DR. JOHN FRIZELLE, of Wheeling, read an intolerably lengthy and monotonous column of manuscript, touching on

THE TERRIBLE DANGERS ATTENDING THE USE OF TOBACCO,
ALCOHOL, ETC.

About an hour was consumed in the elimination of this humanitarian effort. Its effect upon the delegates was disastrous.

The paper was referred to the State Board of Health, with the request that they publish it in their proceedings.

NATIONAL BOARD OF HEALTH.

DR. W. F. VANKIRK, of Grafton, offered the following: *Whereas*, The National Board of Health, by its efficiency and faithful discharge of official duty, has won the confidence and endorsement of the most expert sanitarians both in this country and Europe, and of the medical profession, generally, in the United States; and

Whereas, This society deems it of the greatest importance that the strong arm of the general Government shall be exercised to prevent the introduction of contagious disease into the United States from foreign ports, and there spread from State to State; to co-operate with and aid State and municipal boards when such domestic authorities are unable to control or stamp out epidemic diseases among the people; therefore,

Resolved, That this Society requests the senators and representatives in Congress from West Virginia to use their influence to accomplish such legislation as will secure the perpetuity and usefulness of the National Board of Health in preventing the importation of foreign pestilences and their spread among the people; to co-operate with and aid State and municipal boards of health, when such boards are unable to control and suppress pestilences which are afflicting and killing the people; to encourage investigations concerning the sources and causes of disease among the people, and clothe the central power and authority with a sufficient appropriation of money to enable it to discharge the important trusts committed to its care in a matter creditable alike to the general good of the medical profession of the United States.

Adopted.

DR. S. L. JOHNSON, of Wheeling, read a paper on

PUERPERAL FEVER, WITH SPECIAL REFERENCE TO TREATMENT BY EXTRA-UTERINE ANTISEPTIC IRRIGATION.

He combated the specific theory of causation, and advocated the septic or toxæmic nature of the disease. He suggested that when "puerperal" fever arose apparently from erysipelas or scarlatina it was due to the fact that an atmospheric state was produced by these diseases predisposing to putrefaction of lochial discharges.

He recommended the following classification of grave puerperal diseases: 1, Puerperal inflammation; 2, puer-

peral fever, septicaemia, or toxæmia; 3, zymotic diseases in puerperal women; and gave the following rules for antiseptic irrigation of the uterus: 1, What must be done only by a physician; 2, must be preceded by vaginal irrigation; 3, must be done by gravitation and not by injection; 4, fluid used must be as warm as the body temperature; 5, a free exit from uterus must be secured; 6, concentrated solutions must be avoided.

A discussion ensued at this point as to the use of ergot in labor. DR. S. G. LANDIS, of Columbus, denied the "oxytocic" properties of ergot in his experience, and deplored its use in any of the stages of labor. He thought it acted simply as a nauseant, nauseants being well known to cause contraction of the womb.

DR. R. B. STOVER, of Richmond, spoke at some length in support of Dr. Landis's remarks. DR. J. GREGG, of Quet, Del., was also in the habit of conducting his cases of labor without employing ergot.

MISSOURI MEDICAL ASSOCIATION.

Twenty-sixth Annual Meeting, held at Jefferson City, Mo., May 15 and 16, 1883.

(By Telegraph to THE MEDICAL RECORD.)

ADDRESS OF WELCOME—URGING APPROPRIATION FOR FIRE-PROOF BUILDINGS FOR NATIONAL MEDICAL LIBRARY—DISCUSSION OF THE CODE—THE USE OF THE WORD ALLOPATH—REPORT ON GENITO-URINARY SURGERY—ELASTIC LIGATURE IN SURGERY—THE PROGRESS OF MEDICINE—STANDARD FOR THE EXAMINATION OF STUDENTS.

THE twenty-sixth annual meeting of the Missouri Medical Association opened Tuesday afternoon, May 15th. The Address of Welcome was delivered by Governor Crittenden. He criticised the Code of Ethics and prophesied the abolition of the Code and of the American Medical Association itself. He paid a handsome tribute to the memory of Dr. Hodgins, late President of the Association.

PRESIDENT GORE protested against breaking down the Code of Ethics.

Resolutions were adopted urging upon Congress appropriations for a fire-proof building for the Medical Library and publishing index catalogue.

DR. G. M. DEWEY read a paper, "Remarks with Reference to the Code," which led to an animated discussion.

DR. TODD, of St. Louis, introduced a resolution condemning the use of the word allopath.

DR. FORD, of St. Louis, presented a long report on "Genito-Urinary Surgery," discussing strictures, litholapaxy, etc.

DR. TRADER, of Sedalia, read a brief paper on "The Elastic Ligature in Surgery."

DR. ALLEN reported from the Committee on Medical Legislation the history of the bills passed by the last Assembly.

On Wednesday, May 15th, DR. LESTER presented a report on "Progress of Medicine," referring specially to the bacillus tuberculosis, and the treatment of typhoid fever and of rheumatism by the salicyl compounds. This elicited an extended discussion.

DR. J. W. BRENT read a paper on "Force."

DR. T. POLLOCK, of St. Louis, presented a paper on "Jequirity in Ophthalmia," giving personal observations.

DR. HOLLEY, of Kansas City, presented an abstract of an extended paper on "Pathology and Classification of Tumors."

DR. WARTH's paper on "Spontaneous Evolution" was read by title.

DR. B. F. WILSON, of Salisbury, read a paper on "Bacteria," denying that they can affect normal tissues. This paper was fully discussed in the afternoon.

THE PRESIDENT gave an address recalling some points in the progress of medicine, but showing how far short of

our wishes is that progress, noting also defects of medical education in practical points.

DR. T. J. NORRIS presented a long report of the Committee on Medical Legislation, with letters from prominent physicians in this State and elsewhere. The paper was partly read, and referred without discussion to the Committee on Publication.

DR. ALLEN proposed a resolution containing a recommendation to the Board of Health to fix a certain standard for the examination of students grading from medical schools, and requiring publication of questions and answers. After some irregular discussion an adjournment was had without action on the resolution.

ILLINOIS STATE MEDICAL SOCIETY.

Thirty-third Annual Meeting, held at Peoria, Ill., May 15 and 16, 1883.

(By Telegram to THE MEDICAL RECORD.)

THE Thirty-third Annual Meeting of the Illinois State Medical Society was called to order May 15th, at 10 o'clock by the President, DR. A. T. DARRAH, of Bloomington, who made an address of welcome on behalf of the Committee of Arrangements and the citizens of Peoria, which was responded to by DR. WILLIAM HILL, of Bloomington.

After the routine of business, the arrangements for the reports of the various committees was made, making provision for voluntary reports in connection with the same.

The morning session concluded with the reading of the Annual Address of the President.

Reports on the Practice of Medicine were offered by Drs. N. S. Davis, of Chicago; B. M. Griffiths, of Springfield, and J. F. Todd, of Chicago, which were received. These reports were discussed by several members, among others Drs. S. C. Plummer, of Rock Island; J. P. Walker, of Mason City; D. Prince, of Jacksonville, and B. F. Crummer, of Warren.

The report on Necrosis showed that death had not invaded the members' ranks during the past year.

DR. BOOTH presented the report of a special

COMMITTEE ON MEDICAL EDUCATION,

expressing the desirability of separating teaching and the conferring of diplomas, criticising severely the American system of medical education, and warmly recommending the creation of an

EXAMINING BOARD SEPARATE AND DISTINCT FROM ANY AND ALL MEDICAL COLLEGES.

This caused considerable discussion, the point being generally conceded that the existence of separate examining boards is greatly to be desired.

PROFESSOR W. HAY, of Chicago, as chairman of a special committee, submitted a report relative to the

COMMITMENT OF THE INSANE,

and submitted a brief of a bill to be recommended to the Legislature. The report was accepted, and the committee was continued for two years.

At the Wednesday morning session, reports on Surgery were given by Drs. E. Owen, of Chicago, and J. T. Stewart, of Peoria. The latter related a case of

EXSECTION OF THE UTERUS, OVARIES, AND GREATER PORTION OF THE POSTERIOR WALL OF THE VAGINA, WITH RECOVERY.

DR. VERITY, of Chicago, exhibited an ingenious and simple device for

SUSPENSION DURING THE APPLICATION OF THE PLASTER JACKET.

DR. DAVID PRINCE, of Jacksonville, exhibited an apparatus for evacuation of the bowels, and

DR. J. S. WHITMIRE showed a new spring truss for

which he claimed certain advantages of simplicity and universality of application.

DR. N. HOLTON, of Smithfield, reported a case on the

SPONTANEOUS DISLOCATION OF A KIDNEY

to the anterior part of the abdomen, with a reduction of the same.

The Treasurer, DR. J. H. HOLLISTER, having completed his twentieth year of service, tendered his report through Dr. N. S. Davis, requesting at the same time to be released from service.

The appointing of the Nominating Committee and the discussion of the Reports on Surgery concluded the morning session.

At the Wednesday afternoon session the following resolutions were presented from the Special Committee on Recommendations on President's Address:

Whereas, The Illinois State Medical Association take much interest in

URGING AND PROMOTING THE FORMATION OF THE STATE BOARD OF HEALTH,

and the results of its work since its organization fully justifies the expectation of its friends in protecting the people from professional ignorance and imposition from epidemic diseases and various other causes prejudicial to life and the promotion of a higher standard of medical education, thus placing Illinois in the front rank in this respect among her sister States, this rule being largely due to the personal sacrifices of members of the board, the appropriations made by the State having never been sufficient to carry out the duties imposed on the board by law; therefore be it

Resolved, That in the opinion of this Society, it is the duty of the Legislature of this State to make such appropriations as will enable the board to carry out the important duties assigned it by the acts creating the State Board of Health and the act to regulate the practice of medicine.

Resolved, That a copy of this preamble and resolutions be sent to members of the Legislature now in session. Adopted.

DR. PRINCE, of Jacksonville, and DR. CHENOWETH, of Decatur, and DR. E. S. NORRIS then read papers on gynecology.

THE REPORT OF NOMINATING COMMITTEE

was then presented and adopted.

President—Prof. Edmund Andrews, Chicago; *First Vice-President*—David Booth, Sparta; *Second Vice-President*—Geo. W. Nesbitt, Sycamore; *Treasurer*—Walter Hay, Chicago; *Members of the Judicial Council (for three years)*—Robert Boal, Peoria; Herbert Judd, Galesburg; L. G. Thompson, Lacon; *Committee on Practical Medicine*—J. C. Frye, Peoria; J. W. Hensley, Yates City; N. S. Reed, Chandlerville; *Surgery*—Roswell Park, Chicago; D. S. Booth, Sparta; J. D. Whitley, Petersburg; *Obstetrics*—S. R. Crawford, Monmouth; Ellen A. Ingersoll, Canton; C. Duhadway, Jerseyville; *Gynecology*—W. S. Caldwell, Freeport; L. H. Corr, Carlinville; A. F. Rooney, Quincy; *Ophthalmology and Otolaryngology*—J. P. Johnson, Peoria; Robt. Tilly, Chicago; P. H. Garretson, Macomb. Place of meeting, Chicago, 1884.

During the afternoon session a communication from the Missouri Medical Association, asking that the time of meeting of one of the associations should be changed, was received. The Missouri association was considerably invited to make such change.

Reports on Drugs and Medicine were submitted by Drs. S. J. PITNER, of Jacksonville, and HERBERT, of Galesburg.

After the conclusion of the afternoon session, the delegates were invited to partake of a carriage excursion in the suburbs, and a promenade reception was given in the evening.

INDIANA STATE MEDICAL SOCIETY.

Thirty-third Annual Session, held at Indianapolis, May 8, 9, and 10, 1883.

W. H. BELL, M.D., PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

MEDICAL PAPERS READ—THE NEW YORK CODE IN INDIANA—INSTRUCTING DELEGATES TO AMERICAN MEDICAL ASSOCIATION—ELECTION OF OFFICERS.

OVER two hundred members of the Society were present. The Secretary, Dr. E. S. Elder, reported that the Society was larger than ever, numbering now over 1,200 members. During the past year 44 members had been suspended, 2 expelled, which shows that Indiana doctors are rather uncontrollable, or that the censorship is rigid.

Papers were read by Dr. S. E. Earp, of Indianapolis, on "Typhoid Fever," Dr. G. F. Beasley, of Lafayette, on "A Case of Gunshot Wound in the Knee," Dr. J. M. Green, of Stilesville, on "Typhoid Fever," and by Dr. T. B. Harvey, of Indianapolis, on "The Laceration of the Cervix Uteri." Dr. Mary J. Thomas, of Richmond, read a paper on "The Medical Education of Women of the State," advocating the removal of the restrictions of sex in the reception of students by the colleges.

The paper was really a plea for co-education in the Indiana Medical College. Dr. T. B. Harvey, in reply, said that co-education in that college was impracticable at present.

Dr. George Sutton read a paper on "Human Parasites."

Dr. George Rowland, who had previously posed as an ethical reformer by introducing resolutions condemning the New York Code and its originators, read a paper on "Medical Legislation," which excited the charge of plagiarism. Dr. Boyd, of Dublin, said that it was nearly identical with a paper read by himself two years ago, which paper had been lost by the Secretary.

A paper by Dr. Worrell and one by Dr. Gaddy were read by title.

A resolution was adopted, instructing the delegates from Indiana to the American Medical Association to vote against any change in the Code of Ethics, so far as consultation with irregulars was concerned.

A resolution was adopted, allowing Dr. T. M. Stevens to spread upon the record of the county his defence from the charges made by the State Health Board against him as its secretary, and on account of which he had been deposed.

The following officers were elected for the ensuing year: *President*—Dr. S. E. Munford, of Princeton; *Vice-President*—Dr. Wm. H. Shulse; *Secretary*—Dr. E. S. Elder, of Indianapolis; *Assistant Secretary*—Dr. G. W. Burton, of Mitchell; *Treasurer*—Dr. G. W. H. Kemper, of Munich.

The Society adjourned to meet in Indianapolis on the second Tuesday in May, 1884.

THE SOUTH CAROLINA MEDICAL ASSOCIATION

Held its thirty-third annual session at Yorkville, April 25th and 26th, the President, Dr. F. F. Gary, in the Chair. The annual address by the President was upon the subject of the State Board of Health, which is the State Medical Association. Resolutions endorsing the National Board of Health and asking for a quarantine station at Sapelo Sound were passed.

A committee consisting of Drs. Bralton, Taylor, and Taber, appointed to investigate the subject of anæsthesia, reported with the following conclusions: 1. That for more than fifty years the inhalation of sulphuric ether as an excitant has been common in some parts of Georgia, though not practised in the colleges. 2. That Wilhite was the first man to produce profound anæsthesia, which was done accidentally with sulphuric ether in 1841. 3.

That Long was the first man intentionally to produce anæsthesia for surgical operations, and that this was done with sulphuric ether in 1842. 4. That Long did not by accident hit upon it, but that he reasoned it out in a philosophic and logical manner. 5. That Wells, without any knowledge of Long's labors, demonstrated, in the same philosophic way, anæsthesia by the use of nitrous oxide gas in 1844. 6. That Morton, desiring to use the gas in dentistry, asked Wells to show him how to make it in 1846. 7. That Wells referred Morton to Jackson, as the latter was a scientific man and an able chemist. 8. That Jackson told Morton to use sulphuric ether instead of gas, as it possessed the same properties and was as safe and easy to get. 9. That Morton, acting upon Jackson's suggestion, used the ether successfully in the extraction of teeth in 1846. 10. That Warren, Haywood, and Bigelow performed important surgical operations in the Massachusetts General Hospital, October, 1846, on patients etherized by Morton, and that this introduced the practice throughout the world.

Dr. A. A. Moore read a paper reporting cases to show that chloroform tended to increase the danger from hemorrhage during labor. Dr. T. P. Bailey read a paper on hemorrhagic malarial fever, a form much resembling yellow fever. Dr. John Forrest read a paper on boryglyceride, commending it as an antiseptic in surgery, diphtheria, and ulcers. Dr. J. J. Chisolm, of Baltimore, read a paper in which he urged the use of spectacles by children suffering from optical troubles.

The following officers were elected: *President*—Dr. R. A. Kinloch; *Recording Secretary*—Dr. John Forrest; *Corresponding Secretary*—Dr. H. D. Frazer.

The Association adjourned to meet at Florence, April 22, 1884.

THE MISSISSIPPI STATE MEDICAL ASSOCIATION

Held its Sixteenth Annual Meeting at Meridian, April 4th, 5th, and 6th. Numerous papers were read, among them one by Dr. R. S. Toombs, on a case of "Gin-Saw Injury of the Hand, Forearm, and Elbow-Joint," in which the arm was saved after a very extensive injury. Dr. John Brownrigg showed an apparatus for securing counter-extension in fracture of the femur, a close-fitting jacket being substituted for the perineal band; Dr. Brownrigg also showed an apparatus for the treatment of Barton's fracture. Dr. W. E. Todd read a paper on a case of "Hysterical Convulsions in a Woman with Anteflexion and Endocervicitis Cured by the Galvanic Current." Dr. Mabry read a paper on "Puerperal Convulsions," Dr. Guise a paper on "Veratrum Viride in Puerperal Convulsions," Dr. D. L. Pharis a report on epidemic orchitis, which had occurred during the past year. The following officers were elected: *President*—Dr. J. M. Greene, of Aberdeen; *Vice-Presidents*—Drs. S. N. Walker, and Dr. McCallum; *Recording Secretary*—Dr. W. E. Todd, of Clinton; *Assistant Secretary*—Dr. J. F. Hunter, of Jackson; *Corresponding Secretary*—Dr. M. S. Craft, of Jackson; *Treasurer*—Dr. Robert Kells. The Society adjourned to meet at West Point the first Wednesday in April, 1884.

THE TEXAS STATE MEDICAL ASSOCIATION

Held its Fifteenth Annual Meeting at Tyler, April 24th, 25th, 26th, and 27th, over one hundred members being present. The annual address was delivered by the President, Dr. S. F. Starley, of Corsicana. It was voted that the "Transactions" be published in pamphlet form instead of in the Galveston *Medical and Surgical Record*. Among the papers of interest read was one by Dr. Johnson, who reported the case of a girl six years old, who had menstruated ever since the first week of life. Dr. E. J. Beall and Dr. W. A. Adams reported the case of a large indolent ulcer cured by sponge-grafting. Dr. D. M. Ray read a paper in which he described a very novel

method of removing pins, etc., from the stomach. He gave the patient, who had swallowed a pin, a mixture of mush and cotton; he then produced emesis and the pin was expelled.

The following officers were elected: *President*—Dr. A. P. Brown, of Jefferson; *Vice-Presidents*—Drs. T. H. Nott, J. D. Osborne, and Frank Allen; *Secretary*—Dr. W. J. Burt, of Austin; *Treasurer*—Dr. J. Larendon, of Houston. The Society adjourned to meet next year at Belton, on the last Tuesday in April.

THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

Held its Thirteenth Annual Meeting in San Francisco, April 18th and 19th. The President, Professor L. C. Lane, delivered an address, taking for his subject the climate and diseases of Guatemala, which country he had just visited. He stated that the deaths from phthisis were proportionately very small, being about eight per cent. on the whole mortality. Goitre prevails, but without cretinism. There is a small colony of lepers. The practice of medicine is carefully regulated, and hardly any quackery prevails. Dr. Lane says: "In passing along the streets one is struck with the almost total absence of medical signs; and even if one is seen, it is in characters so small as to be illegible at a short distance." Guatemala has a tolerably good medical college with about one hundred students. The scientific work of the Society was chiefly in the form of reports on the various special branches. Thirteen of these were made, and about the same number of original papers was read.

The Board of Examiners reported that eighty-eight licenses had been given during the year. The Board of Censors recommended the expulsion of Dr. P. D. McD. Miller, *alias* Dr. Francis St. Clair Miller, on the ground that his diploma had been fraudulently obtained. The recommendation was adopted.

An exhibition of the gastroscope was given by Dr. J. O. Hirschfelder.

The Society voted to have the next annual session cover three days.

The following officers were elected: *President*—Dr. Ira E. Oatman, of San Francisco; *Four Vice-Presidents*; *Treasurer*—Dr. F. W. Hatch; *Permanent Secretary*—Dr. W. A. Briggs, of Sacramento; *Assistant Secretaries*—Dr. Thomas Ross and John Wagner. A Board of Censors and Examiners were also elected.

THE SECOND GERMAN CONGRESS OF INTERNAL MEDICINE.

Held at Wiesbaden, April 18, 19, 20, and 21, 1883.

PROFESSOR FRERICHS, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

The number of physicians present upon the opening day was over two hundred, the list including well-known representatives from Berlin, Breslau, Bonn, Würzburg, Göttingen, Tübingen, Kiel, Jena; also from Prague, Vienna, St. Petersburg, Copenhagen, Bern, and Zurich.

The Congress was opened on the morning of the 18th (Wednesday) with an address by the President, PROFESSOR FRERICHS. The speaker congratulated the association upon its rapidly attained success, called attention to the need of a renewed interest in internal medicine, which had threatened to be overtopped by other and minor specialties. He said that the present Congress had three specially important questions to discuss: 1, The germ theory of tuberculosis; 2, the nature, prevention, and treatment of diphtheria; 3, the abortive treatment of infectious diseases.

At the close of the President's address, Drs. Biermer and Liebermeister were elected Vice-Presidents.

The scientific work then began with a paper by PROFESSOR RÜHLE, of Bonn,

UPON THE INFLUENCE OF THE DISCOVERY OF THE TUBERCLE BACILLUS UPON THE PATHOLOGY OF TUBERCULOSIS.

The author gave a history of the various experiments and observations which culminated in Koch's discovery of the bacillus. He reviewed and endeavored to answer the arguments against the view that the bacillus is the specific cause of phthisis. Accepting it as a cause, he urged the use of disinfection, isolation, and antiseptics in the treatment and prevention of the disease. His conclusions were: 1, Human tuberculosis is an infectious disease; 2, the bacillus discovered by Koch is its special cause; 3, the fact that pulmonary tuberculosis may be transmitted from man to man by contagion is established; the exact method is not certainly known; 4, tuberculosis in man and animals is identical; 5, the therapeutics relate chiefly to prevention, but the best methods of prophylaxis cannot yet be formulated.

Professor Rühle's remarks were received with much applause.

He was followed by PROFESSOR LICHTHEIM, of Bern, who agreed in the main with the preceding speaker.

DR. FRAENTZEL, of Berlin, related the results of the experiments made in connection with Koch and Gaffky with the

ANTISEPTIC METHOD OF TREATING PHTHISIS.

They had employed inhalations of menthol camphor, naphthalin, anilin, etc., but with negative results.

PROFESSOR KLEBS, of Zurich, believed it demonstrated that bovine tuberculosis was communicable to man. He thought that a certain predisposition must exist in order that contagion occur, and reaffirmed his old view that the intestinal tract was often the place where the infective virus entered.

PROFESSOR HILLER, of Berlin, had made injections into the lung tissue (in cases of phthisis) of corrosive sublimate, bromide of ethyl, and alcohol, but without any result.

DR. SCHOTT, of Mannheim, recommended salicylate of sodium and sulphurous acid as antiseptics in tuberculosis.

DR. ZEIGLER, of Tübingen, described his views of the way in which the tubercular virus enters the system. He thought that the entrance occurred through three channels, viz., the blood-vessels, the lymphatics, and the lungs. In accordance with this we may distinguish

THREE TYPES OF TUBERCULOSIS.

When it enters by the blood-vessels we usually have general miliary tuberculosis, but in rare cases, especially in children, tuberculosis foci are formed in the lungs, making the disease resemble a localized tuberculosis.

The second form, in which the lymphatics take part, is that which is generally produced by inhalation. A tubercular lymphangitis is excited. The tubercular foci thus formed enlarge, then soften, and their products may be carried further (1) by the lymph paths, or (2) by the blood-vessels, causing an embolic tuberculosis, or finally (3), directly along the bronchi. In this way, or by direct infection, we find developed the third type, or bronchial tuberculosis.

PROFESSOR RÜHLE, in concluding the discussion, called attention to the fact that not a voice had been raised against the view that tuberculosis was an infectious and parasitic disease.

A debate was opened on the second day by PROFESSOR GERHARDT, of Würzburg, on

DIPHThERIA: ITS PATHOLOGY, CONTAGIOUSNESS, THERAPY, AND PROPHYLAXIS.

The speaker reviewed the history of diphtheria, and showed how our knowledge of its infectious and contagious character had gradually been obtained. He

believed in the essential identity of croup and diphtheria. He gave an interesting account of an epidemic of diphtheria among the hens in a village of France. Among 2,500, 1,400 died of diphtheria. One thousand chickens hatched from their eggs died within six weeks. A diphtheritic hen bit an hospital attendant, who soon developed a diphtheria.

Diphtheria, the speaker believed, depended upon the presence of micro-organisms, but these probably carried or generated some chemical poison. They varied in character and appearance, a fact which accounts for the varying course of the disease. The differentiation of various kinds of diphtheria, in accordance with the special micro-organism, was the future problem for the pathologist.

He discussed the question whether the membranous exudate in scarlatinal sore-throat was truly diphtheritic, and was inclined to think it was not.

As regards therapeutics the indications were two: First, the loosening or removal of the membrane, by vapors with lime-water or lactic acid, by pilocarpin or papayotin (which latter he recommended as useful). Second, the attack upon the cause of the disease with antiseptics.

(To be continued.)

THE TWELFTH CONGRESS OF THE GERMAN SURGICAL SOCIETY.

Held in Berlin, April 4, 5, 6, and 7, 1883.

PROFESSOR V. LANGENBECK, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

(Concluded from p. 524.)

THE morning session of the second day was occupied with the presentation of cases.

EXCISION OF TARSUS, REPRODUCTION OF BONE.

DR. LAUENSTEIN, of Hamburg, presented a woman, fifty-four years of age, from whom he had removed the greater part of the tarsus of the right foot, on account of caries, nearly two years before. The under portion of the os calcis, as well as its neck and head, the scaphoid, three cuneiform, cuboid, and tarsal ends of the fourth and fifth metatarsal bones were excised. In addition, the remaining part of the calcaneus was scooped out. The patient could stand at the end of five months, and could at present walk for half an hour without fatigue. There was good reproduction of bone, and the foot was less than half an inch shorter than its fellow.

DR. WÖFLER, of Vienna, presented a report, with specimens, upon

RESECTION OF THE SMALL AND LARGE INTESTINES.

In a case of a woman, fifty-two years of age, the attempt was made to remove a large tumor of the abdomen by laparotomy. Upon opening the abdomen, however, the tumor was seen to be a fibroma of the mesentery. So closely attached was it to the small intestine, that it was found necessary to cut out a strip of the latter, over three feet in length, before the tumor could be removed. The patient died in collapse.

A second case, in which a piece of the transverse colon, six inches in length, was removed with a cancerous tumor, made a good recovery. This was the second successful resection of the transverse colon which the speaker had been able to find. In conclusion, Dr. Wöfler described the steps in the operation of gastro-enterotomy as recommended by him, and detailed the indications therefor. The operation should be attempted in all cases of cancer or ulcer of the pylorus, in which the patency of the opening is impaired by the new growth.

DR. LAUENSTEIN stated that he had made a gastrointestinal fistula in a case of advanced cancerous steno-

sis of the pylorus, but there was no relief of the vomiting or constipation.

DR. SCHÖNBOM, of Königsberg, related a case in which there was

A BALL OF HAIR IN THE STOMACH IN A YOUNG GIRL.

An anæmic girl, suffering also from lateral curvature, had complained for three years of severe gastric pains. Examination after eighteen months revealed the presence of a tumor in the left side of the abdomen, freely movable, of an oblong, kidney shape, about the size of a man's fist, and painful on pressure. The diagnosis lay between a tumor of the spleen or omentum and a floating kidney. The fact that the pain was greater at night and when at rest argued against the latter supposition. The removal of the tumor was determined upon because of the constant vomiting and decreasing strength of the patient. The tumor was found to be a bundle of matted hair lying free in the stomach. It was removed and the patient recovered. She stated that four years previously she had been in the habit, for about a year, of biting off the ends of her hair and swallowing them, with the object of thereby acquiring a clear voice. The mass of hair was black in color and of a kidney shape, or of the shape of the contracted stomach. The patient was a blonde, and the dark color was probably caused by the iron which had been taken. The reporter could find but seven similar cases on record. All of these died either from peritonitis or from uncontrollable vomiting. Death in one case occurred through hæmatemesis.

At the afternoon session Dr. WÖFLER presented an elaborate paper on

THE EXTIRPATION OF BRONCHOCELE,

which he had been unable to read the previous day. There was no further discussion of the subject.

DR. RIEDEL, of Aix-la-Chapelle, presented a report upon

THE RESULTS OF THE BISMUTH TREATMENT OF WOUNDS IN THE CITY HOSPITAL AT AIX DURING THE FIRST QUARTER OF 1883.

His results correspond pretty closely with those obtained by Kocher. He had followed very nearly the directions of the latter, except that he had not employed secondary suture (*Secundänaht*), but rather primary suture and drainage. The bismuth was found useful not only in fresh wounds and operations, but also in cases where suppuration had already occurred. The most beneficial action of this substance seemed to reside in its dryness and tendency to repress secretion, whereby primary adhesion of the wounded surfaces was promoted and septic infection avoided. The author had added to his clinical observations numerous experiments upon animals, which all tended to show the value of this method. He never observed any symptoms of poisoning. Although bismuth was a good antiseptic, still, like the other antiseptics, it was not absolutely unfailing. He had observed erysipelas (during an epidemic) although this method was strictly carried out. He had tried a mixture of bismuth and corrosive sublimate, but even then had had one case of erysipelas. Dr. Riedel desired to hear from the members if they had found corrosive sublimate to be protective against erysipelas. If so, he thought he could recommend the combination with bismuth, in spite of his want of success in one instance. The discussion was postponed until the next session.

The scientific work of the afternoon session of the third day began with a discussion of

THE BISMUTH TREATMENT OF WOUNDS.

DR. KOCHER thought he need only say that further experience had increased his confidence in the value of this method in promoting union by first intention.

DR. VON LANGENBECK had had but little experience in

operative surgery since leaving Berlin, and it was difficult to judge of the value of a procedure of this nature from the results obtained in a small number of cases. In the instances in which he had used it, however, it had served him so well that he could only praise its action. He also, as Dr. Riedel, departed slightly from the rules proposed by Kocher. He closed the wound at once by suture, inserting a drainage-tube, but removed the latter not later than the second day. In one case especially the result was so beyond expectation that he could attribute it to nothing else than the bismuth. It was that of the extirpation of a cavernous angioma situated on the inner side of the thigh. The resulting wound was one apparently most unfavorable for healing by first intention; it was a large, deep hole, whose walls were formed of muscles moving with every change of position of the body. The surface was sprinkled with water holding bismuth in suspension, a drainage-tube was inserted, the edges of the wound were exactly approximated by suture, and over all was applied a bismuth compress. The drainage-tube was removed on the second day, and the wound healed throughout by first intention, without any secretion. He had never seen such a result with other antiseptics, except when deep sutures were used. He would never fill a cavity with bismuth for fear of toxic effects. There was one disadvantage of bismuth as compared with iodoform, that it was impossible with it to obtain healing by a scab.

DR. ISRAEL had had a case in which he regretted his employment of bismuth. It was one of carcinoma of the breast. He amputated the breast, following Kocher's rules strictly in every particular. The wound healed beautifully in ten days, but the patient developed a gangrenous stomatitis, from which she suffered for eight weeks. The same patient presented herself some weeks later because of numerous nodules, about the size of a cherry, which she had noticed in the neighborhood of the cicatrix, and which she feared were cancerous in nature. An exploratory incision showed them to be composed of little collections of bismuth. To a remark of Langenbeck, that it was evident that he had made too free use of the bismuth, Dr. Israel answered that he had followed Kocher's directions implicitly.

DR. HAHN had obtained excellent results from the employment of bismuth, and had never seen stomatitis. He had noticed the beneficial action of the substance in stopping hemorrhage.

DR. KÜSTER, of Berlin, then read a paper upon

THE TREATMENT OF MAMMARY CARCINOMA.

The author condemned the practice of some surgeons who amputated the entire gland for every new growth of whatever nature. In doubtful cases he thought it better to first make an exploratory incision. If the malignancy of the tumor was established, the entire breast should be removed, as well as the axillary glands, even though the latter could not be felt to be enlarged. He had collected the statistics of 132 cases, in 15 of which the mammary gland alone had been removed. Of the latter, 13 died within a short period, from a return of the disease; in 2, a second operation was performed. In the remaining 117 cases the axillary glands were extirpated, with a result of 21.5 per cent. of cures, after a lapse of over three years, and 20.17 per cent. free from a return at the end of two years. In every instance the axillary glands were submitted to a microscopical examination, and in but two cases were they found free from disease.

A somewhat heated discussion followed.

DR. GUSSENBAUER said that he went further, and removed the supraclavicular glands as well as those of the axilla. As far as his observation went, there was scarcely a surgeon who did not extirpate the axillary glands in every operation for the removal of mammary cancer, and therefore he could not discover that Dr. Küster's paper contained anything new.

DR. VON LANGENBECK thought it was of little use to

remove the supraclavicular glands, for when they became involved the disease had usually invaded other organs also.

DR. ESMARCH not only took out the axillary glands but advised amputation of the arm in cases in which the arteries and nerves were involved in the new growth. He had done so in one instance, and his patient was now in good health, free from any return.

DR. VON LANGENBECK approved of this course. He himself had cut away the diseased vessels, nerves, and muscles in three cases. One was cured, one died of a return of the disease, and the other from gangrene of the arm. In future he should prefer to amputate.

DR. KÜSTER, in concluding, expressed his gratification in learning that Dr. Gussenbauer was so convinced of the necessity of extirpating the axillary glands; but he could assure him that there were many surgeons who did not think it necessary to resort to such a radical procedure in every case; and if his remarks were effective in convincing them of their error, he would not regard his labor as having been in vain.

DR. HEUCK presented some statistics concerning

THE OPERATIVE TREATMENT OF CANCER OF THE RECTUM,

in which he showed the successful results of a total extirpation of the tumor by the knife.

DR. KÜSTER then read a second paper upon

THE USE OF IODOFORM IN OVARIOTOMY.

Upon the conclusion of the operation, after the abdominal cavity was thoroughly cleansed, all the presenting portions of the intestine were wiped with a sponge which had been dipped in iodoform, and then shaken to remove all excess of the powder. Thus the peritoneum was covered with a very fine layer of iodoform, enough to insure antiseptis, and not so much as to give rise to toxic symptoms through absorption. An iodoform tampon was also placed in the vagina. The patient made a rapid recovery without the least inflammatory reaction. The speaker also recommended iodoform in collodion, as a simple and effective antiseptic application in wounds of the face, and of other parts on which the ordinary dressings were retained with difficulty.

The only paper read at the last session of the Congress was one by DR. ZABLUDOWSKI, of Berlin, entitled,

THE PHYSIOLOGY OF MASSAGE.

The author based his conclusions upon a number of experiments upon men, in different physical conditions, upon rabbits, and frogs. His investigations led him to believe that nearly all the bodily and mental functions could be influenced by the various kinds of massage. The weight of the body is reduced in corpulent and thin persons, but is increased in those of medium build. Capacity for work and bodily strength is increased. The mental processes become more active, and sleep is rendered more sound and regular. The frequency of the pulse is lowered, motility is favored, and sensibility is blunted. These effects would serve to explain the value of the method in affections of rheumatic and neuralgic nature. Massage also favors resorption, and hence is useful in many surgical diseases of the limbs and joints. The speaker warned his hearers not to attempt to substitute massage for orthopaedia. The former may well precede mechanical treatment, as it renders the ligaments more supple and promotes the absorption of extravasations and pathological exudations. In conclusion, he said that massage should be performed by strong and active men, to whom some knowledge of anatomy and physiology was necessary; without this knowledge massage might well be productive of more harm than good. Medical men should superintend this method of treatment in the individual cases, and should endeavor to avoid a routine treatment for all conditions.

After the transaction of some general business the Congress adjourned.

MEDICAL SOCIETY OF PENNSYLVANIA.

*Thirty-fourth Annual Session, held at Norristown, Pa.,
May 9, 10, and 11, 1883.*

(Special Report for THE MEDICAL RECORD.)

(Continued from p. 522.)

SECOND DAY—MORNING SESSION.

THE Society was called to order by the President, DR. VARIAN, at 9.20 o'clock.

The meeting was opened with prayer by the REV. H. M. KIEFFER, of the Reformed Church of the Ascension.

The following gentlemen were named as

MEMBERS OF THE NOMINATING COMMITTEE

from their respective counties: Adams, A. Knowell; Allegheny, T. J. Gellever; Armstrong, R. S. McCurdy; Blair, W. R. Finley; Bradford, E. P. Allen; Bucks, Joseph Foulke; Cambria, W. B. Towman; Carbon, A. J. Donnelly; Centre, P. S. Fisher; Chester, E. Jackson; Clearfield, S. C. Stewart; Crawford, G. O. Moody; Cumberland, R. L. Sibbett; Dauphin, Hugh Hamilton; Delaware, I. N. Curtin; Erie, I. L. Stewart; Huntingdon, A. B. Brombere; Indiana, William Ansley; Lancaster, J. A. E. Reed; Lackawanna, I. W. Gibbs; Jefferson, W. B. Gibson; Lycoming, J. W. Young; Mifflin, A. Rothcock; Montgomery, S. N. Wiley; Montours, S. Shantz; Northampton, Charles McIntyre; Philadelphia, W. G. Porter; Schuylkill, J. S. Kaland; Snyder, J. F. Kanawald; Venango, S. G. Snowdon; Warren, F. A. Shubert; Westmoreland, J. A. Fulton; York, W. S. Rowland.

THE ADDRESS IN [SURGERY]

was then read by DR. A. CRAIG, of Columbia, who reviewed the progress of that science within the past few years. He advocated the use of the knife as an expedient when all other methods of treatment had failed. He dwelt at considerable length on the treatment of the various forms of fracture.

DR. S. W. GROSS, of Philadelphia, read a paper on

THE THOROUGH REMOVAL OF CARCINOMA OF THE BREAST.

The speaker illustrated his method, which consists in thorough excision and the removal of all the diseased tissues liable to produce recurrence of the malignant growth, by offering the results of fifteen cases occurring in his own practice, seven of which were perfect cures; three of the subjects operated upon by Dr. Gross were brought upon the stage and the cicatrices pointed out to the audience. These scars seemed to move free over the underlying tissues, and in one of the cases, that of a rather fleshy woman, the wound made by the operation, which was originally as large as a dinner-plate, had closed up perfectly.

Dr. Samuel D. Gross, of Philadelphia, and Dr. John L. Atlee, of Lancaster, were invited to take seats on the stage, but declined the honor.

DR. WM. PEPPER, of Philadelphia, was next introduced, amidst applause. His paper was entitled

A CONTRIBUTION TO THE CLINICAL STUDY OF TYPHLITIS AND PERITYPHLITIS.

He said that from his observations he found that the cæcum and the ileum are the seat of very frequent disease. He is convinced that cases of

TYPHLITIS CAN SAFELY BE TREATED WITHOUT THE USE OF LAXATIVES

for several days, and that much harm has often been done, even by the use of mild laxatives. This class of cases partake more of the nature of a surgical than medical disease. The time for performing the operation cannot be definitely stated; but if after eight or ten days signs of inflammation become apparent, an incision

may be made into the bowels. He gave a description of the symptoms and treatment of numerous cases which had been under his treatment.

DR. E. A. WOOD, of Pittsburg, spoke on an

UNAVOIDABLE MALFORMATION THAT SOMETIMES ACCOMPANIES OUTWARD DISLOCATION OF THE FOOT.

He drew models on the blackboard to illustrate his remarks, which were instructive and entertaining.

DR. J. C. WILSON, of Philadelphia, read his voluntary paper on

THE TREATMENT OF PURULENT PLEURAL EFFUSIONS.

According to Dr. Wilson, the treatment of patients suffering from collections of fluid in the pleural cavity, is capable of exceeding favorable results which tend to diminish human suffering and prolong life. The physical signs of such effusions relate, first, to the actual condition of the lung, and, second, to the relative displacement of that organ by pressure. These inflammatory fluid exudations are first fibrino-serous, and second purulent. The hypodermic needle is generally used for the exploratory puncture, but Dr. Wilson prefers the aspirator. In adults after aspirating the pus rapidly reaccumulates. A thoracic fistula should be established as soon as possible. The dangers to life are many: the patient may perish from exhaustion, or from heart-clot, the lung may not expand, necrosis may occur, or gangrene of the lungs or tuberculosis supervene. The real dangers attending the operation are puncture of the lungs and collapse. A preliminary withdrawal of a portion of the pus should be made by aspiration. Morphia, and other stimulants may be given prior to the operation, and salts of ammonia should be administered internally during the treatment. There should only be one puncture made; the external air need not be excluded; a short needle, not exceeding two inches in length, should be used for the puncture, and the cavity should be washed out by means of a ball syringe, and a system of soft-rubber tubing once or twice a day. Of five cases treated in this way, three fully recovered, one died of heart-clot, and one is at present under treatment. Dr. Wilson introduced a young man to show the position of the drainage-tube in the body.

DR. CHARLES K. MILLS, of Philadelphia, read a voluntary paper on

THE MEDICAL SERVICE OF INSANE HOSPITALS.

The substance of his address was as follows: The number of resident physicians in State asylums is entirely too small. There should be an individual examination of every patient. Governor Hoyt's new law makes admirable provisions, but they are impracticable with the present force of physicians. Let steps be taken to provide means to carry out the supervisions of Governor Hoyt's bill. The physicians and attendants are required to do too much routine work. Why not have unpaid resident physicians or internes? The opportunity for study, etc., would be of incalculable advantage to young physicians in their first year after graduation. The number of surgical operations and examinations which such an experience offers are wonderful, as shown by the statistical tables of the Norristown Asylum. There should be in every large hospital or asylum a board of consulting physicians, in deed and not only in name. Each of the board should have a distinct task. Dr. Mills believed that the measures of the Hoyt Committee would do much good.

Some remarks on scarlet fever by DR. E. O. BARDWELL were read by title, and ordered to be referred to the Publishing Committee.

Under new business, DR. C. B. NANCREDE gave a history of a case of carcinoma of the breast which had come under his charge.

DR. LEE made some remarks with reference to addresses on surgery.

The Corresponding Secretary next read his report.
DR. HIRAM CORSON then offered,

A COMMUNICATION FROM THE PHILADELPHIA ANTI-VIVISECTION SOCIETY

protesting against vivisection, and asking that the State Society take some action on that subject.

DR. E. A. WOOD, of Pittsburg, spoke against the paper. He alluded to the poisoned sausages which the Pittsburg policemen throw to stray dogs, causing them to die in great agony. Why did not the society turn its attention to that subject?

The following gentlemen were appointed a committee to act upon the resolutions of the Anti-Vivisection Society: Eskridge, Wood, Keen, and Little.

The following resolution was offered by Dr. W. W. Keen, of Philadelphia.

Resolved, That the Medical Society of Pennsylvania, in view of the very urgent need of

ENLARGED FACILITIES FOR VIVISECTION,

both in the medical schools of Pennsylvania and also by physicians throughout the entire State, a privilege now denied them, most earnestly urge upon the Legislature of Pennsylvania the passage of

THE PENDING ANATOMY BILL.

The resolution was carried.

DR. S. D. GROSS, of Philadelphia, then offered a resolution which was read by the secretary,

TOUCHING THE REMOVAL OF THE MEDICAL LIBRARY AND MUSEUM OF THE SURGEON-GENERAL'S OFFICE TO A FIRE-PROOF BUILDING,

and requesting that resolutions be passed by this Association favoring that removal. These resolutions were adopted by the Society.

COMMITTEES ON MEDICINE, SURGERY, AND GYNECOLOGY.

DR. JOHN CURWEN, of Harrisburg, presented the following resolution: That the President of this Society be requested to appoint a committee of three members on each of the following branches: Medicine, Surgery, Diseases of Women and Children, Ophthalmology and Otology, Nervous Diseases, Insanity and Idiocy, to prepare a series of questions calculated to obtain the history, symptoms, and treatment of the different forms of disease, that when these questions are prepared they be sent to the different members of the Society throughout the State with the request that each member fill out in full one specified case of disease in the list of questions sent him and return the same to the chairman of the committee of that branch; so that by this means

A COLLECTIVE INVESTIGATION OF THE DIFFERENT FORMS OF DISEASE

may be made and thus a more thorough account be obtained of the facts bearing on the disease in all its different stages, and when these answers have been received the different committees shall arrange the facts and present them to this Society. Adopted by the Society.

SECOND DAY, AFTERNOON SESSION.

The Nominating Committee reported the following names for officers for the ensuing year:

President—H. H. Smith, Philadelphia; *First Vice-President*—Ellis Phipps, New Haven; *Second Vice-President*—H. B. VanValseah, Clarefield; *Third Vice-President*—J. W. Kerr, York; *Fourth Vice-President*—S. S. Schultz, Danville; *Permanent Secretary*—William B. Atkinson, Philadelphia; *Recording Secretary*—M. S. French, Philadelphia; *Corresponding Secretary*—J. G. Lee, Philadelphia; *Treasurer*—Benjamin Lee, Philadel-

phia; *Additional Members of the Committee of Publication*—Hugh Hamilton, Harrisburg; James Tyson, Philadelphia; C. S. Turnbull, Philadelphia; *Members of Judicial Council*—A. Rothrock, McVeytown; G. O. Moody, Titusville; William Pepper, Philadelphia. The society to meet next year in Philadelphia. John B. Roberts, Chairman of the Committee of Arrangements; his associates to be selected by the Philadelphia County Medical Society.

Resolved, That this committee recommends that the Publication Committee be instructed to have the transactions of the Society printed and ready for distribution within three months from the date of the final adjournment of the Society.

A resolution was offered by the Secretary and adopted by the Society, providing that the President and Permanent Secretary fill any vacancies occurring in the national and various State delegations.

THE ADDRESS IN OBSTETRICS

was read by DR. G. O. MOODY, of Titusville. The speaker referred at some length to the various means for the prevention of abortion. He advocated the early use of the forceps. When greater reliance is placed upon the use of the forceps and less upon the administration of ergot much better results will ensue. On obstetrics, he spoke of the uses and abuses of Tarnier's forceps; he concluded that this instrument was one of unquestionable value. He then passed to a consideration of the various therapeutical appliances and remedies for the treatment of puerperal convulsions, support of the perineum, etc.

Other papers read were "Address in Hygiene," by Henry Leffman, of Philadelphia; "Our Asylums and Our Insane," by Sayres, of Pittsburg; "Surgical Expedients in Emergencies," by R. J. Levis, of Philadelphia; etc., etc.

DR. BENJAMIN LEE, the Treasurer, offered the following report of the Society's financial condition: Balance on hand May 11, \$1,965.68; receipts through year, \$2,269.91—total, \$4,235.59. Expenses during year, \$1,871.75. Balance on hand, \$2,363.84.

The same gentleman, as chairman, also offered the following: The committee appointed at the last meeting of the Society to memorialize the Legislature of this State with reference to

AMENDING AND CODIFYING THE LUNACY LAWS.

now on our statute books, beg leave to report that soon after their appointment the government of the State anticipated their proper action by appointing a commission for the very purpose contemplated in the resolution. They therefore considered that further action was unnecessary and beg to be discharged.

The report was adopted.

DR. WILLIAM T. LITTLE, of Philadelphia, read a paper upon

REFLEX UTERINE DISEASE FROM IRRITATIONS OF THE EYE,

in which, after tracing the irritations of the eye from the uterus, as described by Professor Forster, of Breslau, he next traced the influence of the eye upon the nervous system and various organs as described by S. Weir Mitchell, of Philadelphia. He desired to report a case where a chain of reflex symptoms extended to the uterus impairing its function, and relative sterility ensued and lasted for twelve years. This case also presented various nervous and physical symptoms.

The subject of

THE HIGHER MEDICAL EDUCATION

was discussed at some length at the close of the day's proceedings, by Drs. S. D. Gross, James Tyson, William Ulrich, etc.

In the evening receptions were held at their homes by the members of the Montgomery County Medical Society.

THIRD DAY—MORNING SESSION.

The third day's session was called to order at 8.30 on Friday morning by PRESIDENT VARIAN, and a blessing invoked by the REV. A. J. WEDDELL, of Norristown.

The new order of business was then called for, and DR. E. J. JACKSON, of West Chester, moved the adoption of the following :

Resolved, That at each annual meeting the President appoint one member to deliver, at the next yearly meeting, an address on "Ophthalmology and its Relation to General Medicine."

DR. W. S. LITTLE, of Philadelphia, moved to amend by adding the subjects Otology and Laryngology.

The resolution and amendment were both warmly discussed until DR. W. T. BISHOP, of Harrisburg, demanded that the regular order of the day be called.

The President sustained his point and introduced DR. JOHN CURWEN, of Harrisburg, who delivered

THE ADDRESS ON MENTAL DISORDERS.

It is most assuredly a subject demanding the most earnest and persevering investigation by the profession to trace out the cause of the peculiarly intractable character which mental and nervous disorders have lately assumed, to discover, if possible, the reason why they are so. In such investigations it is desirable and important to keep constantly before the mind the error into which all are likely to fall, of confounding cause and effect, and thus nullifying the correctness of the results to be attained. No one doubts but that physical diseases are transmitted from parent to child. That we cannot explain the reason does not invalidate the fact, and to endeavor to discover that reason should be our prime motive. In certain families part of the children will be found to have not only the physical peculiarities of one parent, but also that parent's mental idiosyncrasies, while the other children will have all the physical and mental traits of the other parent. In many cases actual disease may be transmitted from parent to child, and this tendency may be traced back through several generations.

To the indulgence in intoxicating drinks is unquestionably due much of the moral depravity, want of true principle, and attendant mental inability to exercise proper self-control, or to resist certain forms of temptation, which characterizes the rising generation. In this fact of the impaired physical condition of the mother also lies the explanation of the great difference sometimes observed in certain members of a family who seem to be constituted diversely (mentally and morally) from the other children. During the period of gestation the mother should be enlivened by cheerful scenes and impressions of every kind, so that the mind may be led into bright and healthful thoughts.

During infancy and early childhood the greatest care must be given to the child's physical condition, so that it may be strengthened for that course of discipline and school education through which all should pass. The necessary activity of the first few years of life needs to be regulated, not restrained. The child should not be kept at school too closely, as this form of restraint has the double effect of increasing the child's irritability and its dislike of its lessons to be learned. Too close an application at an early age is apt to strain the mental powers, and in this way retard development. The steady, continuous influence of a good example will do more than precept upon precept to impress upon the mind of the child the important lesson that true happiness is always to be secured. A true and healthful education consists in such a cultivation of each of these states that one shall not preponderate over the other. Ample and regular nutrition is essential to the proper growth and development of the body. Next in importance to nutrition must be ranked sleep, to recruit the exhausted powers. Those who do the best work and the largest amount of it are

those who carefully observe these requirements. Observation has clearly shown that those who make the greatest apparent progress in early life are not those who hold out to the end, while those who are more slow are more sure to retain and better able to make use of that knowledge. Bodily and mental habits have also a decided influence on the functions of the different organs.

The following voluntary papers were then read : "Diagnosis, Prognosis, and Treatment of Mitral Constriction," by Dr. J. T. Eskridge, of Philadelphia ; "Lithæmia," by Dr. J. B. Walker, of Philadelphia ; "Clinical Notes on the Use of Convallaria Majalis," by Dr. E. T. Bruen, of Philadelphia.

The resolution offered at the opening of the morning session by Dr. Edward T. Jackson was then adopted.

DR. HENRY LEFFMAN, of Philadelphia, on behalf of the Philadelphia County Medical Society, presented an amendment to the Constitution of the State Medical Society, the purport of which was that hereafter no paper should be read before the Society unless it had been previously read before a county society, and by them referred to the State Society.

Action on this amendment was postponed for one year.

The resolutions of respect adopted by the Montgomery County Medical Society on the death of Dr. David Shrack, of Jeffersonville, were read and ordered to be printed in the Transactions.

At eleven o'clock the Society adjourned, and were conveyed by a special train to the State Hospital for the Insane in the Southeastern District of Pennsylvania, situated just outside the city limits. The members were accompanied by their wives and daughters. Arriving a little before twelve, an hour was spent in a tour of some of the male and female wards, the resident physicians acting as guides. No one could fail to be impressed with the great cleanliness everywhere apparent.

The area covered by the buildings is immense. There are now nine hundred and sixty inmates, male and female, black and white, yet there is no indication of crowding.

After doing justice to a substantial and well-arranged cold collation, in a long hall of one of the new buildings, the Medical Society re-convened in the Asylum Chapel.

DR. MAYNE, a trustee of the Asylum, spoke briefly, and, while hoping that the results of the inspection had been satisfactory to the visitors, expressed, nevertheless, the firm intention of the managers of the institution to persevere to the end in the course which they are now pursuing.

In some respects, he continued, the Norristown Hospital for the Insane is different from, and in advance of, the other similar institutions in the State. Its leading physician, or superintendent, is not burdened with its material interests, and is not forced to cater, or make contracts for coal, wood, provisions, etc. In another respect, also, it is generally conceded that the Norristown Asylum is managed in a more progressive spirit—it has an independent female physician at the head of the female department, of powers equal to, and coordinate with those of the male physician in charge.

At the conclusion of Dr. Mayne's remarks Dr. Wm. Thompson, of Philadelphia, was invited to occupy a seat on the platform and participate in the proceedings.

The Secretary then read an invitation from the physicians of the Philadelphia Hospital for Skin Diseases for the Society to visit that institution that evening.

INCREASE OF MEDICAL STAFFS IN INSANE ASYLUMS.

DR. B. LEE read a resolution to the effect that the State Medical Society, after listening to the able papers on insanity which had been read at its present session, resolve that the popular idea that sane persons are incarcerated in insane asylums is an unworthy aspersion on the medical profession, and that the State Legislature be made to feel the necessity of making such appropriations for these institutions as will warrant the increase of their medical staffs.

The paper expected from Dr. M. Landesburg, of Philadelphia, on "Stretching the Optic Nerve," was not read, owing to that gentleman's absence.

One of the most novel and, to the general profession, most interesting papers presented during the session was that then read by Dr. J. M. ANDERS, of Philadelphia, on the

HYGIENIC MANAGEMENT OF CONSUMPTION,

in which he claimed that the effect of plants on the atmosphere of houses is not only beneficial, but almost a specific preventive in cases of incipient consumption. House plants exhale a great deal of aqueous vapor, and may so increase the humidity of the atmosphere to any desired extent. It is now known that flowering plants emit ozone, and so the atmosphere of the living rooms may be very beneficially medicated. Half of all cases of consumption are known to be preventible, and persons threatened with this disease have, in all known cases, escaped it as long as they lived and worked among house or hot-house plants. Thirty Philadelphia florists, who work from ten to sixteen hours a day among hot-house plants, had been found to confirm this theory to a remarkable extent. In a consumptive family of a father and two sons, the father and one son were healthy until they abandoned their business as florists, but died almost immediately afterward. The other brother, after working all his life among growing plants, went into the "cut-flower business," and died in less than a year.

Other striking cases were cited. Dr. Anders spoke of the purifying influence of house plants on the air, and the relief and amusement afforded an invalid in caring for them. They should be kept in a living- or sleeping-room of not less than 12 x 20 feet, with a southern exposure, and arranged so that the sun would strike them. A temperature of from 68° to 74° F. should be maintained in the room, and soft, thin-leaved plants, with large foliage, should be chosen, such highly scented flowers as the tuberose being excluded.

Resolutions of thanks to the Montgomery County Medical Society, the officials of the Norristown Asylum, etc., were passed.

DR. E. H. WOOD, of Pittsburg, made some remarks on insane asylums, speaking in the highest terms of praise of the management of the Norristown Hospital.

DR. VARIAN, before resigning the chair, made the following appointments for the annual meeting of 1884, in Philadelphia: Address in Medicine, Dr. W. H. Daly, Pittsburg; Address in Surgery, Dr. J. B. Roberts, Philadelphia; Address in Obstetrics, Dr. J. Price, West Chester; Address in Hygiene, Dr. J. G. Lee, Philadelphia; Address in Mental Disorders, Dr. Alice Bennett, Norristown.

After thanking the members for their kindness and courtesy, Dr. Varian then yielded his place to the new President, Dr. H. H. Smith, of Philadelphia, who adjourned the Society after a few words of thanks.

In the evening a reception was tendered the members by the Philadelphia Polyclinic and School for Graduates at its rooms at the southeast corner of Thirteenth and Locust Streets, Philadelphia. Many ladies were present as well as a number of invited guests.

A large delegation of the members also visited the Philadelphia Hospital for Skin Diseases, No. 923 Locust Street, and were received by Dr. J. V. Shoemaker and his assistants. Refreshments were served in the parlor of the hospital.

THE SITE OF THE INITIAL LESION OF SYPHILIS.—In 120 male patients examined by Mr. Bernard (*Liverpool Med. Chir. Jour.*, January, 1883), the site of the initial lesion was—the furrow, 53 times; the inner prepuce, 57; the outer prepuce, 10; the free margin, 2; the corona, 31; the glans, 10; the sheath, 18; the meatus, 6; the frænum, 6 times; and the urethra once.

MICHIGAN STATE MEDICAL SOCIETY.

Eighteenth Annual Meeting, held at Kalamazoo, Michigan, May 9 and 10, 1883.

(Special Report for THE MEDICAL RECORD.)

(Continued from p. 522.)

SECOND DAY, MORNING SESSION.

THE Michigan State Medical Society resumed its session at Kalamazoo, Mich., at 9.30 A.M., Thursday.

THE COMMITTEE ON ADMISSIONS

reported favorably upon over fifty names.

The application of Dr. George A. Hendricks was reported on adversely. He had issued a circular letter, which he had sent wherever he thought it safe, urging attendance at this meeting, evidently for electioneering purposes.

After a heated discussion his case was referred to the Judicial Council.

From the first there has been an effort on the part of a few to capture the Society for Professor McLean of Ann Arbor.

Many came up under the impression that the University and Professor McLean were to be attacked, but seeing how matters stood refused to support McLean for the Presidency.

DR. TYLER presented the report of the Committee on Nominations.

PROFESSOR VAUGHN, of the University, offered as a substitute a full set of nominations in the McLean interest. Several of the most prominent nominees of the substitute list refused to accept, and the committee's list was elected.

DR. A. F. Whelan, of Hillsdale, was then unanimously elected *President*. The other officers are: *First Vice-President*, H. Tupper, Bay City; *Second Vice-President*, J. S. Hamilton, Tecumseh; *Third Vice-President*, H. B. Barries, Ionia; *Fourth Vice-President*, Augustus Keiser, Detroit. The *Secretary* holds over another year. *Judiciary Council*, Foster Pratt, Kalamazoo; H. B. Sank, Lansing; S. P. Duffield, Dearbornville.

DELEGATES TO AMERICAN MEDICAL ASSOCIATION.

H. C. Wyman, J. B. Book, Wm. Brodie, L. Connor, H. O. Walker, L. Shirly, Detroit; E. E. Dunsler, A. B. Palmer, W. F. Breakey, Ann Arbor; Foster Pratt, Kalamazoo; A. R. Smart, Hudson; J. H. Bennett, Coldwater; J. Andrews, Pawpaw; S. S. French, Battle Creek; C. H. Lewis, Jackson; F. H. Owen, Ypsilanti; Y. M. Hurd, Pontiac; Hugh McCall, Lapierre; A. F. Hagadorn, Bay City; J. H. Jerome and L. D. Bliss, Saginaw; W. U. Smart, Grand Haven; S. R. Shepherd and C. V. Beebe, Manistee; W. E. Dockery, Pentwater; M. A. Duckinson, East Saginaw.

The following papers read by title were referred to the Committee on Publication: "Plaster-of-Paris as a Surgical Dressing," by H. O. Walker; "Water and its Relations to Health and Disease," by J. R. Post; "Etiology of Urethral Inflammation," by H. J. Reynolds. Dr. H. B. Baker, of the State Board of Health, read

A PAPER ON DIPHTHERIA.

He claimed it was epidemic. The death-rate appeared as a wave, more fatal in cold months, but not necessarily in cold years. Did not seem to be much influenced by known conditions of filth. Length of waves between points of greatest mortality in city, five or six years; country, fourteen. More fatal in children.

DR. PRATT called attention to the subject of exposure, and DR. WORCESTER related the history of a series of cases which occurred in the asylum.

DR. BRODIE considered simple diphtheria non-contagious, malignant, or contagious. Diphtheria was always complicated with scarlatina. He thought placarding houses did no good but harm, by alarming the people.

DR. SMART reported a case in which a brass glove-

button had been carried in the ear of a patient for thirty years without having been discovered, though the patient had a purulent otorrhœa all the time.

DR. WARD read a poetic effusion, entitled "Pro Bono Professorium."

The committee to whom the President's address was referred brought some questions before the society for discussion.

PROF. PALMER called attention to

THE HIGH REQUIREMENTS OF THE MEDICAL DEPARTMENT OF THE MICHIGAN UNIVERSITY.

He denied that the professors were unprofessionally advertised, and that they took time for themselves which belonged to the University.

After further speeches by Professor McLean and others the matter was referred for publication.

Grand Rapids was decided upon as the place for the next meeting.

After seating the new President, and passing the usual resolutions of thanks, the Society adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 25, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

DR. CARPENTER, in behalf of a candidate, presented microscopic sections of carcinoma of the breast.

DR. KUCHER presented what he believed to be a portion of

THE SAC OF AN ECHINOCOCCUS,

which came from a patient whom he saw with Dr. Bradbury, a woman, fifty years of age, who five years ago had what was supposed to be an ovarian cyst. She was examined by Professor Schroeder, who doubted that the cyst was ovarian. Although it increased in size rapidly it was not operated upon. Shortly afterward the patient had an attack of pleurisy, and during that sickness she discharged from the rectum a slimy, gray fluid, which gave her very great relief. On examination the tumor in the abdomen had disappeared, and afterward she felt quite well. Six months ago she came to this country, and one week ago she discharged from the rectum the mass which Dr. Kucher presented. On the following day she was up and felt very well, except that her abdomen was somewhat tender to the touch. On examination he found the liver increased in size, and in the lower part of the abdomen a tumor about the size of two fists. Otherwise the patient feels quite well. The material discharged from the rectum had been washed and made completely clean before Dr. Kucher saw the specimen. He had examined it microscopically, and found it to be a structureless membrane, which led him to the conclusion that it was a portion of the sac of the echinococcus, although he was unable to find any hooks. He thought there was a sac somewhere in the abdominal cavity, that a communication with the intestines had been established, and that a portion of the sac had been discharged. He was unable to say whether the echinococcus had originated in the liver or not, although that organ was considerably enlarged. Perhaps it was from the omentum, as occurred in Dr. Schnetter's case, reported a few years ago.

DR. WACKERHAGEN presented a specimen of

CARCINOMA OF THE BREAST

with the following history: Mrs. C—, aged sixty-two years, widow, born in Ireland, came under his care on March 24th. In July last she noticed a small tumor in the right breast, but as it caused no inconvenience, she did not consult her physician, Dr. Rooney, until November, when it had grown as large as a medium-sized orange. She was then suffering some pain from the growth, but would not consent to an operation for its re-

moval. After this time the tumor grew more rapidly, the patient suffering severely from lancinating pains. The patient was anæmic and somewhat emaciated, but had always enjoyed good health. The operation was performed on March 27th. The longest diameter of the tumor extended diagonally upward and outward, involving the axillary glands, and had formed attachments to the axillary vessels and nerves. The body of the mass extended upward, involving a considerable portion of the pectoralis major. It also extended about one inch below the lower border of the breast. The entire tumor was firm, resisting, and surrounded by fat, which also penetrated deeply and lay between the fibrous bands in large quantity. The weight was nineteen ounces.

There was very little hemorrhage during the operation.

She rallied from the effects of the anæsthetic, complaining of severe pains in the wound; pulse rapid and feeble. A hypodermic injection of morphine was administered, followed by stimulants. After resting quietly for three or four hours, she awoke, complaining of severe pain and difficulty in breathing. Stimulants were continued, but the patient gradually sank, and died about eight hours after the operation.

Post-mortem examination not permitted.

DR. W. P. NORTHRUP presented a specimen, with the following history:

TUBERCULAR ULCER OF COLON—GENERAL TUBERCULOSIS.

Female; two years eight and a half months old; New York Foundling Asylum. The case was entered on outdoor book in the spring of 1882, as "bronchitis and enteritis;" in January, 1883, "diarrhœa." Was returned to the house January 15, 1883, "pale, restless; no vomiting, no diarrhœa, no febrile movement." Drank but little. Sent out again to nurse. Returned three days later, the nurse saying that the child would not take food. Convulsions. Died 3 P.M., June 18th.

Symptoms of bronchitis and diarrhœa and "delicate" condition extend back about one year.

Autopsy, January 19, 1883.—Body: Well nourished; skin clear and clean. Larynx and œsophagus: Normal. Lungs: Bronchial glands cheesy and large; left, congested, scattered lobules of pneumonia, adherent at apex by few fine adhesions; right, slight amount congestion. Liver, spleen, and kidneys: Normal. Intestines: Mesenteric glands enlarged, some as large as a hickory nut, and cheesy in centres. Small—Peyer's, patches of lower half of ileum ulcerated; edges raised and rounded; deep excavation in centre; in upper half the patches are congested, dusky, not raised. Large—Large ulcer in cæcum, about $\frac{3}{4}$ by $1\frac{1}{2}$ inch, extending obliquely across axis of gut; another similar ulcer near the middle of the colon extends nearly vertically across the axis of the gut; this is smaller than the first. Of these ulcers the borders are thickened uniformly for some distance around, the whole intestinal wall being involved; the bases are coarsely granular, sunken; margins are extensively undermined, so that they appear rounded and crenate or puckered. On the peritoneal surface covering the region of the ulcers are numerous miliary tubercles. Scattered about the mucous membrane of the colon are numerous enlarged solitary follicles.

On cutting the lungs, subsequently, they were found studded with miliary tubercles.

Microscopic examination of the ulcers of the colon shows numerous tubercle granula with many giant-cells. The induration about the ulcer is due to infiltration of tubercle-tissue. The ulcers in the small intestine show no tubercle tissue. Numerous sections from different ulcers were examined to make this statement satisfactory.

The interest in this case is mostly pathological. Though general tuberculosis is of frequent occurrence,

tubercular ulceration of the intestines is not frequent, and an ulcer like the specimen was unique in his experience.

DR. NORTHRUP also presented a specimen of
CHRONIC FOLLICULAR COLITIS IN A CHILD TEN MONTHS OLD,

with the following history. Male child; ten months old; New York Foundling Asylum. October 27, 1882, entered in out-door department; "condition poor; papular eczema; face thin, peaked; whines." "Marasmus." Returned December 26th; "condition miserable; continues to grow worse." Remained in house one week; diarrhoea constant; nothing peculiar about stools.

Autopsy, January 6, 1883.—Body: Emaciated, otorrhoea; both pinnæ deeply ulcerated and excoriated; excoriations about buttocks; sprue on tongue in abundance, less on gums and buccal surfaces; weight eight pounds two ounces. Brain: Normal. Lungs: Bronchial glands slightly enlarged; left, small amount pneumonia in posterior portion; old adhesions over sides and front; right, extensive pneumonia in lowest lobe posteriorly; pleura thickened; no adhesions. Heart: Normal; weight, one ounce. Stomach: Normal. Intestines: Small, normal; mesenteric glands skirting them normal; large, throughout whole extent sprinkled with clean-cut, circular, "punched-out" ulcers, involving mucous coat; these ulcers are about like solitary follicles in distribution, and seem to have removed the follicles by ulcerative process; mesenteric glands skirting the large intestine, large and hard; contents of colon, dark greenish, and apparently for most part made up of curdled milk and mucus. Kidneys: Urates in straight tubes; the tissue appears normal. Liver: Normal; weight, six ounces and two drachms. Spleen: Normal.

Microscopic examination.—The lungs show ordinary broncho-pneumonia. Colon shows simply follicular ulcerative colitis; the solitary follicle is wholly removed by the process; surrounding tissue not involved; some follicles are just breaking down, though most are in an advanced stage.

TEMPERATURE IN URÆMIA.

DR. J. C. PETERS referred to a case of chronic Bright's disease, in which the patient had suffered so little that she had not seen a physician, but was suddenly seized with difficulty of breathing, and died within three minutes. At the autopsy there was found evidence of well-marked oedema of the lungs and of chronic disease of the kidneys.

DR. VAN GIESON asked if it was not unusual to have low temperature in the uræmia of Bright's disease. Had not the elevation of temperature in uræmic poisoning been regarded as a guide in making a differential diagnosis?

DR. RIPLEY said that a few years ago attempt was made to establish as a fact that the temperature in uræmic coma is elevated, while in apoplexy it is lowered, thus furnishing a ready means of making a differential diagnosis between these two conditions. After a little time, however, exceptions were noticed, and it was also determined that the temperature in apoplexy varied considerably according as it was taken immediately, quite soon, or several hours after the stroke. On the other hand, it was found that the temperature in uræmic coma did not always rise, that sometimes it fell toward the close of life, and occasionally reached a very high point.

DR. VAN GIESON said that he had made a large number of observations in cases of uræmic coma and had invariably found the preagonistic temperature above the normal. In the last case, two hours before death, the temperature reached $106\frac{1}{2}^{\circ}$ F. He could imagine that in cases of apoplexy there might be possibly some interference with the heat-centre which would give rise to

elevation or other changes in temperature, but he believed that in the majority of cases of uræmic coma the preagonistic temperature would be found considerably above the normal, whereas in cases of atheromatous degeneration of the arteries the temperature is usually low.

DR. RIPLEY said that with the general statement made by Dr. Van Gieson he agreed, and only wished to say that elevation of temperature did not invariably occur in uræmia, and that, in his opinion, a differential diagnosis could not be based safely upon the temperature alone. It might be said that, as a rule, the temperature in uræmia is elevated.

DR. CARPENTER referred to cases, seen in hospitals, of well-marked uræmic poisoning and coma, in which the temperature was not elevated, and special attention had been directed to them because of this fact, the visiting physicians regarding them as evidence against the claim that the temperature is invariably elevated in uræmic coma.

(To be continued.)

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE MEDICAL COUNCIL—PROPOSED NEW EDITION OF THE PHARMACOPŒIA—THE LONDON HOSPITALS AND THEIR FINANCES—THE LONDON COLLEGE OF PHYSICIANS AND ITS FELLOWSHIP.

LONDON, April 28, 1883.

THE Medical Council is now holding its general meeting, having commenced its deliberations last week. One of the most interesting items is the announcement that the Council have appointed a committee of three pharmacists to prepare a new edition of the British Pharmacopœia. It is proposed to omit three drugs and add twenty-nine. Other changes are at the same time to take place, with a view to increased accuracy. It is proposed to assimilate it somewhat to the United States Pharmacopœia, by substituting the use of proportional parts, wherever possible, for that of specific weights and measures.

The simultaneous appeal made by two large London hospitals—St. George's and the London—for funds, has drawn considerable attention to the financial state of these institutions. A few of them, such as Guy's and St. Bartholomew's, are so richly endowed that they have little need to appeal to outside charity. It is far otherwise with most of them. The London Hospital, our largest metropolitan hospital, having nearly eight hundred beds, has just made an appeal for £150,000 to enable its work to be carried on for five years. A few years ago a similar appeal was made. Standing as it does almost alone in the midst of a population of two millions the calls upon it are indeed great. Still, it would appear that no pains are taken to check the indiscriminate hordes of out-patients applying for relief. It has the largest and the hardest worked staff in London. The out-patient department in all our hospitals stands in need of reform. It has been suggested that the out-patient department of hospitals should be, to a large extent, closed, and provident dispensaries established in the vicinity to which out-patients should be drafted, being there placed under the care of local medical men who would receive salaries for their services.

The London College of Physicians is rapidly losing ground with the profession. It has lately put itself in opposition to the medical bill in a manner that has called down the animadversions of all the journals and many of its own members and fellows. But it has throughout its long history been obstructive. So this is nothing new. Many years ago it refused its fellowship to obstetric practitioners on the ground that they performed operations. This is not now the case, but still of late years I have

heard much discontent at the cliquism displayed in electing to the fellowship. I should explain that there are three orders, viz.: Licentiates, quite a new grade started in 1869 for general practitioners; members, who are *bona fide* physicians and admitted by examination only; fellows, who are chosen from amongst the members by election only. Nominally, the existent fellows elect the new ones to the number of eight or ten yearly; really, the council elect, for they, sitting in secret conclave, prepare a list which the fellows always pass. It is believed by many that nepotism and favoritism reign supreme. I often hear that the only way to get promotion is to toady some of the officials in some way. I know that relations and protégés often get promoted while abler men are passed over—men who despise toadyism and are left out in the cold. As a surgeon I can look on and smile. Last week a new list appeared of members elected to the fellowship, and it is astonishing to peruse it. Some are good men and none can be objected to, only that others more distinguished are passed over in favor of their juniors. One does not like to single men out, but I may say that there are men who have been for years physicians to large hospitals, teachers in our medical schools, honored officers of medical societies, distinguished officers in the public services, and others with many other claims who have been passed by. Many names could be mentioned that are well known both on the Continent and in the United States, and are everywhere respected, but their holders are simply members and have been so for years. To show you how real is the grievance, I may say that two medical men lately picked out from the official list of members in ten minutes no fewer than sixty who had joined since 1859 who could be said to be fairly deserving of the honor of the fellowship—if, indeed, it be an honor. Many of them can justly be said to be far superior to men who have been made fellows, and comparing them with the latest list of promotions, any ten of the sixty would make as good a show. This was not so much to be wondered at when a weak man like Bennett was President, but better things were expected from Jenner, who has the credit of being a strong man and one disposed to do what is right.

THE ANTAGONISM OF MORPHINE AND ATROPINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: In a valuable communication which appeared in THE MEDICAL RECORD of May 5th, Dr. Wallian gives the details of four cases of opium-poisoning treated in part by the administration of atropine. In his remarks on these cases, Dr. Wallian inadvertently commits me to a statement which is not justified by anything I have said or published. His expression is, "recalling the antagonistic ratio existing between atropia and morphia, as stated by Bartholow, viz., atropia, gr. ss. to morphia, gr. j.," etc. In another place in the same communication he again says: "Yet Bartholow, as stated, and other good authorities, insist that it requires one-half grain of atropia to antagonize one grain of morphia." In my "Manual of Hypodermatic Medication" (4th ed., p. 227), and in my "Cartwright Lectures" on this topic, as also in my "Treatise on Materia Medica and Therapeutics" (4th ed. See articles on opium and on belladonna), I have very distinctly stated that the ratio of antagonistic action is about one-twentieth or one-twenty-fourth grain of atropine to one grain of morphine.

The importance of such a mistake must be my excuse for troubling you with this communication, and for calling in question the statements of Dr. Wallian, whose otherwise excellent paper well deserves careful examination. Before closing I must thank a former pupil, Dr. C. W. King, now on the staff of the Cleveland Asylum for the Insane, for calling my attention to Dr. Wallian's

error. As a "constant reader" of THE MEDICAL RECORD. I must have seen this paper, nevertheless, in the course of the week after its appearance. Thanking you in advance, I am, my dear Dr. Shradly, very truly,
ROBERTS BARTHOLOW.

PHILADELPHIA, May 10, 1883.

MEDICAL CONTROVERSY AND THE NEWSPAPERS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Under the heading "Medical Controversy and the Newspapers," you publish on page 528 of your issue of May 12th, a letter from Dr. T. H. Squire, of Elmira. His acknowledged reputation in the profession for both scientific attainments and superior morals render it necessary that I should take notice of it. Thus I ask you to publish the following statement: I never knew, until I was informed of it by Dr. Squire's letter, that the *Tribune* of May 3d published (a translation of) my letter addressed to a large number of German physicians of the city and State. This letter was printed on April 10th, and mailed to every individual German physician in New York, Brooklyn, and Richmond County, also in Albany, whom I knew, or knew to be German. Most of the city letters were enclosed in a two cent envelope. Many of the letters were directed and mailed by a clerk, who may have sent a few to such whose names (taken from the register) may have appeared to him to be those of "German" physicians. A few copies were also sent to friends in the counties, with the request to distribute them amongst the German physicians, if any there were. A solitary copy was given by me to a medical friend in this city, who was not a "German," but demanded that copy from me. Thus it follows that my letter was a personal one in every instance, and not meant for the newspapers at all. Where the *Tribune* obtained its specimen, or who made the translation for it, I cannot know.

The purpose of my letter is best illustrated by its final remarks: "It is far from me to try to prejudice you. What I desire to impress upon you is but this, that you may not commit and bind yourself without an accurate examination of the subject (viz., the Code question). The question is not one of the relation of medical science to medical sects, for that question no longer requires an answer—but of our, your, individual relation to the sick, of conscience, and of the personal independence guaranteed to each citizen by the usage and the laws of the commonwealth. It is my main object to request that you may, in regard to the subject under consideration and the general interests of the medical profession, grant such attention and co-operation as any community—professional, municipal, or State—is entitled to expect from every educated and thinking member and public-spirited citizen."

In view of the fact that of the large number of German physicians but very few give the required attention to, and co-operation in public affairs—a fact best substantiated, if by nothing else, by the small number of German names appearing in the lists of our medical societies—I think every public-spirited man in the profession, no matter of what code party, ought to welcome every attempt at rousing them from their apathy and indifference, which are the more intolerable the higher the scientific accomplishments of very many amongst them.

In regard to the tone and contents of my letter, I claim that no statement of any man who has taken a decided party stand on any question, could be more quiet or impartial.

The correction of Dr. Squire's, in regard to the "majorities," I accept. I am glad he found nothing else to object to. After all it is a great satisfaction to be one of the "one hundred and five."

Very respectfully yours,

A. JACOBI, M.D.

NEW YORK, May 15, 1883.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 5, 1883, to May 12, 1883.

BARTHOLF, JOHN H., Captain and Assistant Surgeon. The extension of leave of absence granted April 3, 1883, further extended four months. S. O. 105, par. 8, A. G. O., May 7, 1883.

BILLINGS, JOHN S., Major and Surgeon. By direction of the Secretary of War, to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Cleveland, O., June 5, 1883. S. O. 105, par. 10, A. G. O., May 7, 1883.

FORWOOD, WM. H., Major and Surgeon. By direction of the Secretary of War, to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Cleveland, O., June 5, 1883. S. O. 105, par. 10, A. G. O., May 7, 1883.

SMITH, JOS. R., Major and Surgeon. By direction of the Secretary of War, to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Cleveland, O., June 5, 1883. S. O. 105, par. 10, A. G. O., May 7, 1883.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending May 15, 1883 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria	Small-pox.	Yellow Fever.
<i>Cases.</i>								
May 8, 1883.....	5	8	166	9	170	44	1	0
May 15, 1883....	0	5	132	4	163	39	0	0
<i>Deaths.</i>								
May 8, 1883.....	0	5	28	9	24	25	2	0
May 15, 1883.....	2	4	30	6	25	19	0	0

The total mortality for the week ending May 12, 1883, was 668, of which 94 were from pneumonia.

THE TWO DOCTORS.—The following is told of Dr. Channing (*Medical and Surgical Reporter*): "The reverend doctor and the medical doctor were both at a party in Boston one evening, and, some one being taken ill, the man of medicines, Dr. Walter Channing, was summoned. The servant entered the room where the brothers were seated, and said, 'Dr. Channing is wanted.' 'Which Dr. Channing?' said Walter, the physician; 'the one who preaches, or the one who practises?'"

NEWPORT MEDICAL SOCIETY AND THE CORONER QUESTION.—In behalf of the committee appointed to consider the present system of coroners the undersigned would respectfully report: That the coroner system, as usually constituted, of non-medical men, is not in accordance with the advanced intelligence and needs of the present time; and that, even when the coroner is a medical man, the antiquated encumbrances of the system are so decided as to occasion very serious disadvantages. Therefore the committee recommend the replacement of the whole system of coroners by that of the medical examiner, as in the State of Massachusetts; and as a means toward this end that a special committee, to con-

sist of Drs. Rives, McKim, and Fisher, be requested to prepare a draft of a law in accordance with the Massachusetts statutes, incorporating therein the slight modifications suggested by Dr. Alfred Hosmer, President of the Massachusetts Medico-Legal Society. The committee further recommend that the said draft, when accepted by this society, be presented in its behalf, by the President and Secretary to the State Assembly, with the prayer that it be made the law of Rhode Island; and that a copy of the draft and petition be communicated to the State Medical Society, with the request that it at once take concurrent action. All of which is respectfully submitted. SAMUEL W. FRANCIS, M.D., Chairman; FRANCIS H. RANKIN, M.D., of Committee.

A QUACK ARRESTED.—Dr. O. C. Gage, of New York, who has extensively advertised himself as the man so celebrated for his wonderful cures in New Hampshire, was arrested at Dover, N. H., May 5th, at the instance of a medical student, who charged him with practising medicine without a license from some medical society of the State.

GOOD WORK AND BAD IN MEDICINE.—The following graphic sketches of two types of professional workers are from a recent address of Dr. Andrew Clark :

In the work of the younger members of our profession I see, or at least I think that I see, greater care, patience, and accuracy in observation, a more rigorous fidelity in the record of therapeutical experiments, wiser caution in speculation, graver deliberation in judgment, a growing frankness in the confessions of oversights and errors, increasing severity in the sifting and testing of their own conclusions, a readier effacement of personality in the work, less unseemly eagerness for mere priority of publication, a deepened sense of the responsibilities of premature speech and writings, a rapidly abating bitterness in the conflicts of opposing views, a more robust and manlier spirit of scientific life, and less reluctance in making admission that there is no unconditional truth in the results of our inquiries—no finality in our finished work—no creed in medicine.

But, for one competent and conscientious worker there are ten incompetent and unconscientious, and who in divers ways hinder our progress and spoil our present possessions. Intolerant of the patient and painful toil of the true worker, acute in power of superficial observation, gifted with a certain showy versatility, quick at catching hold of new ideas, ingenious in guessing, crude in experiments, loose in therapeutic trials, hasty in speculation, strong in dogmatic assertions, accomplished in the transfiguration and use of other men's work, finding what they want wherever they seek, unhindered by difficulties, facile in speech, ready in writing, thirsting for notice, such men, now, alas! not uncommon in medicine, beget papers so quickly that they can have no necessary relation to time, observation, or thought, and flood our literature with their unworthy if not unvarnished lucubrations.

The favorite hunting ground of such men is therapeutics, and their favorite sport is the catching of new remedies, the putting of them to new uses, and the setting forth of their successful results. These men discern no difficulties and have few failures; they can illustrate their successes by scores of cases, and explain them by the most ingenious theories. There is scarcely any limit to the extent or the variety of their achievements; and, as they flaunt along in the fulness of self-satisfaction, they look down with pitying condescension upon those in the strait and narrow way, who conscientiously toil with small success in seeking after truth, but who, nevertheless, missing the praise of men, find strength and solace in the sacred search.

THE NUMBER OF FEMALE MEDICAL STUDENTS in the University of Paris in 1880-81 was 52, in 1881-82 it was 39; of whom 10 were French, 11 English, 5 Americans, and 9 Russians.

Original Lectures.

THE DETERMINATION, BY THE GENERAL PRACTITIONER, OF THE NECESSITY FOR WEARING GLASSES.¹

By D. B. ST. JOHN ROOSA, M.D., LL.D.,

PROFESSOR OF DISEASES OF THE EYE AND EAR IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL; SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL; PROFESSOR OF DISEASES OF THE EYE AND EAR IN THE UNIVERSITY OF VERMONT.

LECTURE III.

GENTLEMEN: You will very often hear patients say that their eyes have been overused, and that for this reason their vision is deficient. I think experience is rather against the likelihood that great use of the eyes necessarily impairs the sight. The best eyes, like the best brains, are those which are used most. The use of eyes forms no exception to the general rule that the organs of the body are the better for employment. They are all the better for being used under proper conditions. The fact that an eye has become presbyopic, does not at all prove that that eye has been overused. Very indolent people, who seldom overtax their eyes, sometimes have very poor sight. In practice, I never regard it as intrinsic evidence that a man has been a very great student merely because his eyes have given out. I must have other proof than the existence of useless eyes. The function of adapting the eye to vision at different distances is called accommodation, and the employment of it will not necessarily injure the eyes. Therefore you are often to encourage this ordinary action of the eyes as a curative means. The continuous employment of the eyes upon fine objects, without breaking the tedium of it, is sometimes harmful. But all of you must know men and women who, while using their eyes constantly in what are called trying employments, never are troubled with asthenopia or with inflammatory affections of the eyes. Long ago exact observers showed that watch-makers and others, who used one eye at a time, and almost constantly, have just as good eyes as mechanics who scarcely use their eyes, or as the idle men about town who read nothing but the newspapers, and of these very little. Remember, if you please, as a preface to your knowledge about the eye, that ordinary eyes are better for being used.

I have talked to you concerning hypermetropia and myopia, and there remains, of the forms of disturbance of vision to be discussed in these lectures, the condition known as presbyopia, or far sightedness.

Fortunately, I am able to show you, to-day a case which illustrates not only hypermetropia but also presbyopia. Perhaps the general practitioner might ask what is the difference between conditions which require the same remedy?

Hypermetropia is an error in the refraction of the eye, that is to say, the hypermetropic eye has not sufficient refractive power. The myopic eye has a refractive power that is too great. The presbyopic eye may be either hypermetropic or presbyopic, or it may be *emmetropic* or of normal refraction. *Presbyopia is a failure of accommodation.* It is a condition that does not necessarily have anything to do with an error of refraction. What-

ever the refraction of the eye, presbyopia must occur if more than forty years of life are passed.

If a person is hypermetropic, he has an eyeball that is congenitally too short from before backward, and he needs convex glasses. If a person has reached the age of forty years or over, and is no longer able to read the finest type at a convenient distance he also needs convex glasses.

Now, you ask what is the difference between these two conditions? Are they identical? By no means.

The little girl present at our first lecture has the condition known as hypermetropia. She has an error of refraction. The refractive power of her eye is insufficient. In the man present at the second lecture, one of my staff, who has myopia, the refraction is too great, the rays of light that enter the eye are bent too much. In the latter case the eye is too long, in the former case it is too short. Your lecturer has passed beyond the age of youth, he has turned the corner, which means that he is among middle-aged men, and he has become presbyopic in the natural course of things. But my eyes were never hypermetropic. I could always read the bottom line of the test-types, since these tests have been suggested, at twenty feet, and the weakest convex glasses before my eyes blur my distant vision throughout. Besides, the fundus of my eyes was examined by an expert ophthalmoscopist, and said to be emmetropic; that is, my eyes when at rest are adapted to parallel rays. But the time has come when, although I can still read the bottom line with perfect distinctness, my accommodation is beginning to fail, and I cannot read fine type at eight inches from my eyes. I will show you the nearest point at which I can read "Jaeger No. 1," or "brilliant" type. According to Donders' table the near point of a man of forty-four should be eight inches. But I find that it is often at nine or ten inches, in an average light. When the near point has come to be farther off than eight inches, presbyopia is reached. The near point of your lecturer, for *brilliant* type in this light at the age of forty-four is nine and one-half inches.

This recession of the near point, from the weakness of the ciliary muscle, and from the loss of the elasticity of the lens, describes far-sightedness, or presbyopia.

But, on making a test in your presence, I find that in this fair light mine is nine and one-half inches. I think it is usually found as far off as that in an emmetropic eye past forty-three years of age. In practice, when the near point of vision for fine objects is beyond eight inches, there begins to be inconvenience in reading fine print (unless the illumination is exceedingly good), in sewing, in detecting foreign bodies on the cornea, in short, in any use of the eyes on near and small objects. This change always comes as a surprise.

We are very apt to ascribe the results of failure in the power of the ciliary muscle and senile rigidity of the lens to other causes than the real one. When a person talks much of the poor type they have nowadays, of bad gas, and has at the same time reached forty or forty-five years of age, an examination of the distance of the near point, and the application of weak convex glasses will often clear up the mystery of the change that has come over the sight.

Myopia and hypermetropia are errors of refraction; emmetropia, the normal condition of refraction; presbyopia, an error of accommodation, and it appears as life advances. It does *not* depend upon flattening of the cornea, it does not depend upon alteration in the length

¹ Delivered at the University Medical College, Session of 1881-82.

of the eyeball from before backward. It depends, as I have already intimated, upon diminished power in the ciliary muscle. The inevitable processes of time have begun. The ciliary muscle is no longer able to contract as vigorously at forty as at twenty-nine years of age. In addition, this perfectly transparent lens, with its capsule and its tubular contents, has become less yielding.

These are the two factors which have rendered the presbyope unable to thicken his lens by muscular contraction; that is, to perform the act of accommodation with the same vigor as he did when he was a younger man. The presbyope, for certain occupations, at least, such as reading the finest type, etc., is doomed to the necessity of seeking artificial aid by means of glasses. But I will now show you the case of which I spoke, which combines an error of refraction with this error of accommodation; that is, a case in which both hypermetropia and presbyopia exist. It is a case perfectly within your capabilities of diagnosing with these test-types, and with this case of glasses. Pleasant and profitable as it may be to use the ophthalmoscope to determine an error of refraction, it is not necessary in this case. This woman is fifty years of age, and has worn glasses about fifteen years. She began to wear glasses, then, at the age of thirty-five, a period in life at which she had no right to wear glasses as a presbyopic person. What is technically known as presbyopia does not begin until after forty years of age. The near point never recedes in a healthy eye farther than eight inches, that is, there is no natural change in the accommodation until after forty years of age. We are, therefore, at once interested in her statement that she began to wear glasses at the age of thirty-five years. She first used them for reading, and she does not remember having used them before that time. We have discovered that the error in this case is not myopia, because the patient who wears glasses for reading at thirty-five years of age, but does not wear them for looking at objects at a distance, is certainly not myopic. Myopia does not necessarily require glasses for reading, unless the myopia is of a very great degree. We have discovered, then, that the condition of her eyes differs from myopia. She has not worn glasses for going about the streets or in her ordinary avocation.

Let us next test her vision by means of the test-types. We find that V. R. E. is $\frac{2}{300}$, and V. L. E. is the same, $\frac{2}{300}$, and with both eyes open her vision is a little clearer than with either one blinded.

Now we will try and find out what kind of glasses she has been wearing. How can that be done? Simply passing them between the fingers does not amount to much, but with my case of glasses and test-types I can tell exactly. I take the glass that has been worn, shut one of my eyes, hold it before the other several inches away, and then look at the test-types, and I find that everything is blurred; the glass obscures my vision. It may be a concave or a convex glass that does this. If a convex glass, a concave glass will certainly neutralize it. So I will take up a concave glass of thirty inches focal distance and put it before this glass, and now I can see a glimmer of the letters. That shows that I am going in the right direction, and the glass which the patient has been wearing is undoubtedly convex. If I had added a *convex* glass it would have increased the indistinctness of my vision.

I put on another concave glass, correcting the glass worn by the patient until I can see the large letters distinctly and in their natural size.

With a concave glass of twelve inches focal distance, put before the glass being corrected, I see the letters larger than they should be, as the glass is still more convex. I wish to have a glass that will make these letters look as though seen with the naked eye. By the next trial I find that No. 11 neutralizes the patient's glass, and I see the letters as though looking through a plain glass. The glass worn by the patient is undoubtedly convex, and the number is probably 10. The patient now tells us that she was ordered to buy No. 10.

I have now settled, beyond question, that she is not myopic if she can read with this convex glass. You will please notice where she is holding the book, although wearing a convex glass, in order to read fine type; it is at a distance exceeding eight inches. At the distance of sixteen inches she can pick out letters. But the glass is too weak; it does not correct the condition of things there. She has something more than presbyopia. She is not myopic. Now what is she? She must be hypermetropic and presbyopic.

In the next place, let us correct her hypermetropia. Let us put on a pair of glasses which makes the eyes of the proper length for distance. If I find that she reads with a glass having a twelve-inch focal distance, but that this does not enable her to read from eight to twelve inches, her glass is not strong enough for near objects. Even a presbyope, in the beginning of his trouble, can read at nine or nine and a half inches. The rule in fitting glasses for presbyopia is to order a glass with which fine type, No. 1 Jaeger (brilliant), can be read at eight inches from the eye; of course it can then also be read at a greater distance.

I will try one eye at a time. I will put on a No. 14 convex glass with the view to correcting her hypermetropia, which is of a different form from that seen in the little girl presented at the first lecture, who could see with or without glasses. Here is a patient who cannot see well at a distance without glasses, and we will now see if she can do any better with them. With her right eye she can read, aided by a glass having fourteen inches focal distance, the bottom line at twenty feet. This is a case of *manifest* hypermetropia. Her vision is not distinct at a distance, unless aided by a convex glass. The left eye is very much like the right. With a convex glass of fourteen inches focal distance her vision becomes normal; her hypermetropia is converted into emmetropia.

Now about her reading. If you have followed me carefully in this course of lectures, you are able to say whether she will need a stronger glass to read with or not. She is not particularly concerned about her distance vision, or she would have had glasses for that purpose long ago. She has not worn glasses habitually. Very comfortable and clear vision for all ordinary purposes is consistent with an inability to read the bottom line of Snellen's test-types at twenty feet. $V = \frac{2}{300}$. If patients have never had more visual power than $\frac{2}{300}$ or $\frac{2}{400}$, they do not always appreciate $\frac{2}{300}$. One of my myopic and astigmatic patients, a lady, whose vision was made normal by glasses which she began to wear for the first time when she had reached middle life, complained that objects appeared too distinct with them, and that "the beautiful haze" was taken away from the scenery of the world.

Another, however, also a lady, under the same circumstances, after having walked down Broadway, and having looked at the shops with her new concave cylindrical lenses, turned about and walked immediately up again, saying that she had never enjoyed the street before.

It is an interesting fact that some patients who have not worn glasses habitually, do not estimate them as having much advantage, even if they do not see well without them. Certain myopes, who can scarcely see large objects *six feet away* from them, will say that they see perfectly well, and object to using glasses, and positively state that they do not care to see any better. They will even deny, after their vision is increased from say $\frac{2}{300}$ to $\frac{2}{200}$, that they see practically any better. The fact is that these tests by letters at a distance, do not furnish to all patients satisfactory subjective evidence of visual power. That is only found out by tests with small type near at hand, and by looking at familiar objects. This patient has no special inconvenience in looking at a landscape. This fraction, $\frac{2}{300}$, does not express her real vision. If she could not see to read or sew, she would be inconvenienced. Now, does she need thicker glasses for reading than for looking at a distance? If so,

a glass of fourteen inches focal distance will not answer. Look at this diagram, and then you will be able to tell me. Here is illustrated an eye of the same kind we are studying; the eyeball is too short, and a glass has been put in front of it to bend the rays of light so that they will take the course indicated by these dotted lines. Now, suppose I change these rays to those coming from an illuminated page, or from a lady's sewing—change their direction so that they are no longer parallel but divergent, does it take a thicker lens to focus divergent than parallel rays? Certainly it does. We need more refraction; a greater breaking up of the rays of light. If this patient requires a glass with a focal distance of fourteen inches to see objects illuminated by parallel rays, she will need a stronger glass to read objects illuminated by divergent rays.

I proved to you, a few minutes ago, that a glass with ten inches focal distance was not strong enough, because she could not read No. 1 test-type nearer than sixteen inches, and indistinctly. I will take a glass having six inches focal distance, I think, because I have found that the near point recedes further than eight inches, which is the dividing line between presbyopia and emmetropia even with the glass. To correct the presbyopia and bring it back to the normal, it is necessary to give a glass with which she can read the finest type at eight inches. The glass that will correct her hypermetropia, added to that ordinarily used by a presbyope of her age, will be the one which will enable her to read fine type at eight inches. This will be one of about seven inches focal distance in her case. I try one of seven inches focus.

She fancies it is rather strong; but with that fancy we are not to be particularly impressed, but we are to prescribe that glass with which she can see No. 1 easily at eight to twelve inches, which will be the one generally needed for fine work in the evening, when the light is not perfect. Then you can allow a little for other work, giving a weaker glass for daylight.

I therefore prescribe it and one of fourteen inches focal distance for going about at work, if she chooses to wear it.

We might imitate Dr. Franklin, and have a glass made after his suggestion, the upper part of which would be of fourteen inches focal distance, for looking about, and the lower part of seven inches focal distance for fine work.

This is a typical case illustrating manifest hypermetropia, to which has been added presbyopia, and the general practitioner may be perfectly competent to diagnose this condition. When vision can be made $\frac{2}{3}$ with a glass, or the person can read the finest type without a glass, it is not necessary to have an ophthalmoscope nor a large case of glasses in order to diagnosticate these conditions of refraction and accommodation, and to prescribe for them. I see from different neighborhoods, where the general practitioner has paid no attention to the advance made by a knowledge of the different spectacles required for the improvement of vision, case after case that has been neglected, which should be treated successfully by some of the recent graduates from the University or Bellevue or the College of Physicians and Surgeons. Some practitioners are so absorbed in the diagnosis of pneumonia, which can be readily made out, that they have had no time to attend to the little and more obscure matters that might enable them to relieve many persons from serious inconvenience and even danger. I hope that, with your test-types and glasses, you will, before dismissing them, at least see whether or not it is within the bounds of your knowledge and experience to correct the condition of their eyes. I have shown you three typical cases, and you should, as general practitioners, be competent, without any special knowledge, except that which I have indicated, to diagnosticate and prescribe for them with correctness.

There is one interesting point in this patient's case. Hypermetropia may remain latent for years and years,

and finally the eyes break down, and it becomes manifest. This patient may have been able, as a school girl, to read $\frac{2}{3}$; but, as time went on, her ciliary muscle weakened, the natural refractive condition of the eyeball appeared, and she was no longer able, by any extra amount of force she possessed, to make the lens thick enough to see parallel rays, and she then needed glasses for a distance.

I remember the case of a judge who came to me in great distress, saying that he was becoming blind; that he was no longer able to see the lawyers in front of him. He had worn glasses for several years for reading, and had always been able to see at a distance, and I found that his entire blindness depended upon hypermetropia, which had suddenly become manifest, so that he was obliged to wear convex glasses for distance. For years, by an extraordinary strain upon the ciliary muscle, he has been able to see distinctly at a distance, but his accommodative power suddenly gave out one day while in court, *hinc illæ lacrymæ*.

FACULTATIVE HYPERMETROPIA.

This gentleman, one of your number, complained of asthenopia; that is, weakness of vision. The first thing I did was to find out whether or not he could read the bottom line at twenty feet. He was able to do so without glasses. But he complained that he was unable to continue to read; that the eyes watered, etc. I found that he could see just as well at a distance, that is $\frac{2}{3}$, with glasses having thirty-six inches focal distance, and I made my diagnosis, without an ophthalmoscope, that it was a case of facultative hypermetropia, voluntary hypermetropia; that is, he is hypermetropic or not, as he chooses. I said to him, "Your trouble is because you are using your ciliary muscle too much. You are using it to see objects at a distance, and also for reading. In a natural condition you are only required to use it in work upon near objects. If you will put on convex glasses and relieve your ciliary muscle from some of the strain, if my diagnosis is correct, if no general condition exists which causes paralysis of accommodation, you will be able to get on very comfortably." He is wearing the glasses, and he says that he can read without inconvenience. With the glass of thirty-six inches focal distance we have relieved the ciliary muscle, which was busily engaged in thickening this lens; in other words, we have relieved the strain upon it, and the asthenopia disappears. It is a case of facultative hypermetropia relieved by the use of convex glasses for the near point. This patient will become like the patient who has just gone out. The time will come when he will not be able to see the bottom line at twenty feet; will not be able to adjust parallel rays to an exact focus, and then he will have manifest hypermetropia, and require convex glasses for distance as well as for objects near him.

CHLOROFORM NARCOSIS DURING SLEEP.—Dr. S. Murrill, of West Liberty, Ia., writes: "In your issue of April 28, 1883, I have read with interest an article on chloroform narcosis during sleep, and I contribute my item of experience. I was requested to remove a tooth from a little girl, Mabel D—, aged five, daughter of Herbert and Almira D—, who now reside in the village of Potsdam, N. Y. The child was nervous and afraid, and would not allow me to even look at the tooth. I approached her while sleeping, put her under the influence of chloroform, and extracted the tooth, which was a front upper one. There was very little hemorrhage. The child showed no signs of awakening. I watched her for some time, and she quietly slept on until morning. Some time the next day she noticed the tooth was gone, but had no knowledge of when or how it had taken its departure. I would suggest that Dr. John H. Gardner, would try it again. It succeeded in my solitary case, and that is the only time I have had occasion to try it."

IS 'THE BLOOD A LIVING FLUID?'

By FRANCES EMILY WHITE, M.D.,

PROFESSOR OF PHYSIOLOGY IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

THE question, Is the blood a living fluid? announced as the subject for discussion at this meeting, is, to the physiologist at least, if not to the pathologist, a most interesting one, since it involves some consideration of living matter in general and the characteristics by which it is distinguished both from matter which has never lived and from that which has ceased to live. The so called vital functions, common to all grades of living matter, vegetable as well as animal, may be briefly stated to consist in such an interchange of materials between any organism and its environment as serves to maintain the chemical and structural integrity of that organism.

The life of the various tissues of any complex organism, though in some sense distinct from that of the organism as a whole, may nevertheless be defined in identical terms with that of the body of which they form a part. Says Professor Huxley: "The preservation of the life of the tissues from moment to moment is a physiological act consisting in successive and simultaneous degenerations and regenerations of parts." In other words, vital processes are *nutritive* processes, nutrition and denutrition going on to some extent simultaneously, though by no means with always equal steps. But these two processes—nutrition and denutrition of tissues—though mutually dependent, stand in very different relations to the functions of the organism *considered as a unit*. The processes of assimilation are concerned solely with the welfare of the tissues, as tissues. The activities of the organism, considered as a unit, are accomplished by means of denutrition, *i.e.*, the retrograde metamorphoses of individual tissues or parts of tissues, which thus complete their functions only in dying—the potential energy stored up in the assimilation of materials obtained from food becoming kinetic in their breaking down. Thus the production of secretions, the movements of respiration, the activity of the heart as an organ of the circulation, the voluntary movements, emotion, volition, and thought, are all immediately dependent on the breaking down of certain constituents of the various tissues concerned. Work means waste, and the measure of the activity of any living mechanism is to be found in its excretions. Thus, increased muscular exertion is accompanied by increased escape of CO₂ in the expired air, and intellectual work adds to the labor of the kidneys in eliminating the greater amount of excrementitious salts thereby added to the blood. That tissue-waste during any given period is not, however, necessarily commensurate with the matter at the same time assimilated by any given tissue is proved by the whole history of metabolism in the body.

It may be said, probably without fear of contradiction, that the processes of nutrition are localized in cells—that the cell alone is the essentially vital structure; and there exist biologists (notably Beale among the English) who limit vital activity, in their belief, to certain parts of the cell, mainly the nucleus, which they regard not only as the chief agent in the reproduction of the cell but in its nutrition also, the outlying portions consisting largely of formed material in which nutritive changes have ceased. It is, nevertheless, through changes in this formed material, rather than by the activity of the living matter, that the function of the tissue is accomplished. Whether or not the views of Prof. Beale and his followers be wholly accepted, it must be admitted that only certain parts of the tissues of any complex organism are, strictly speaking, living. The heart of the oak is physiologically dead, playing a purely mechanical rôle in the life-history

of the tree, whose vital processes are carried on in other parts of its structure.

This is an extreme example of a principle which holds good, though to a less extent, in animal organisms; and a large part of the tissues which make up the bodies of adult animals have, in a great measure, lost their resemblance to the living formative protoplasm from which they were derived.

It is only certain portions of cartilage and bone, for example, which have the power of reproducing new tissue out of pabulum; the other parts consist of formed material which has no reproductive power and which serves a purpose as purely mechanical as that of the heart of a tree.

So in the case of the actively secreting glands, it is the formed products of their nutritive activity which break down to supply the characteristic organic constituents of their respective secretions which then serve their purpose in the body. So also the glycogenic function of the liver is completed only when the glycogen, built up as a part of the hepatic cells, breaks down into the sugar necessary for maintaining the normal constitution of the blood. To what extent these principles may be applied to the chief active tissues—the muscular and the nervous—it will be difficult to determine until more is known of the *modus operandi* of these tissues; it may, however, at least be doubted whether biologists are in a position to refute the theories of Dr. Beale in denying life to everything but bioplasm.

But probably the real question before this Society is somewhat more restricted in its scope than the one just considered, and may be stated as follows: Can the blood be regarded as a true tissue, having a definite origin, structure, and function; also undergoing phases of growth and decay, of repair and waste, like the solid tissues of the body?

In this inquiry, the first point to be established is what constitutes a tissue.

If we restrict our statement to the more simple forms of nerve and muscle tissues, all tissues may be described as alike consisting of cells and an intercellular substance or matrix. The various kinds of cells are also marvelously alike—tissues differing far more in respect to their intercellular substance than in their cells. The cartilage cell, the bone-cell, the connective-tissue corpuscle, the epithelial-cell, the non-striated muscle, and the nerve-cells, may all be described in terms almost identical. May the blood also be regarded as consisting of cells and an intercellular substance differing from cartilage—for example, in having a liquid instead of a solid matrix?

In other words, is the red-blood corpuscle (which, for brevity's sake, I will designate as a *hamacyte*) a true cell? If it be admitted that the hamacyte is derived from the leucocyte and represents the adult stage of the white-blood corpuscle, the question is at once answered in the affirmative; for the white-blood corpuscle (first discriminated from the red by Hewson) is well-known as a living, amœboid cell; it has been seen by Klein to multiply by simple division, and its curious movements (first observed by T. Wharton Jones in the blood of the skate¹) have since been watched by many eyes; these are evidences of life which cannot be adduced in the case of many cells which are nevertheless considered as belonging to living tissues. Moreover, whether the red bodies be recognized as arising from the white, or, as claimed by Hayem, from certain intermediate corpuscles (designated by him as *hæmatoblasts*, and by Klein as *microcytes*) or from some as yet undiscovered source, they have a definite form and chemical composition which they maintain in the midst of a plasma differing materially from themselves, since they contain all the iron of the blood, and a large proportion of the fats as well as of the phosphates and the potassium salts, while the chlorides and sodium salts predominate in the plasma.

¹ A Paper read before the Montgomery County Medical Society.¹ Philosophical Transactions, 1846

These cells also perform a definite physiological function. What more can be said of any cell in support of its claim to being considered as the active element of an anatomically distinct and living tissue?

The complex body of any of the higher animals may be regarded as consisting of tissues, all of which have not only been developed by and differentiated from the original protoplasm of the fertilized ovum, but each of which corresponds in its perfected function to some one of the fundamental properties of protoplasm, to the manifestation of which, in a highly developed degree, it is especially devoted in the interests of the organism as a whole, on the important principles first spoken of by Milne-Edwards as the *physiological division of labor*. Each tissue, nevertheless, retains in its own private interests, as it were, vestiges of many of the other properties belonging to their common ancestor. Thus, all the tissues are assimilative to the extent of keeping up their own nutrition; all are to some degree irritable; all are capable of reproduction of their own kinds of cells, and so on. To what extent can these statements be applied to the blood? What property of protoplasm is specialized in this fluid, and what common protoplasmic properties does it retain?

Pflüger has said that "albumen lives" (that is, becomes protoplasm) "when it begins to take in oxygen"—a power exalted to the highest degree in the hæmacyte, which, to this extent, not only establishes its own claim to being regarded as a living cell, but that of the blood to a place among the true tissues.

The fully developed, non-nucleated, red-blood corpuscle in its state of formed material has undoubtedly lost the power of reproduction—a power which belongs to all tissue-cells—but that it has this power at some stage of its existence scarcely requires proof.

In the embryo the first red corpuscles are derived from mesoblastic cells of the vascular area, and they increase by simple division; at a later stage of embryonic life, hæmacytes are produced by transformation of leucocytes (which probably arise in the liver and spleen and pass thence into the blood) and by transformation of connective-tissue corpuscles; in the spleens of adults, also, as well as in the large capillaries of the red medulla of the bones, small nucleated red corpuscles, similar to those seen in the embryo, have been observed (Rollett). Both von Recklinghausen and Golubew have watched the actual conversion of colorless into colored cells in blood drawn from the body of a frog and kept in suitable conditions of moisture and warmth. The proofs of this transformation in human blood are, it must be admitted, indirect, and dependent on analogy and reasoning rather than upon actual observation. Among these indirect proofs may be mentioned the fact that although leucocytes are constantly being poured into the blood from the lymph-ducts, appearing in excess after any special influx (as following a full meal), their number nevertheless maintains a remarkable uniformity in proportion to the hæmacytes. The rapid regeneration of red blood after hemorrhage, which appears to be promoted by the administration of iron in connection with a generous diet, also admits of the same explanation, while in the blood of leucæmic patients *nucleated* red-blood corpuscles are often found presenting the appearance of the nucleated embryonic blood-corpuscles of mammals and of man (Rollett); and since the red corpuscle is not known to reproduce itself in the blood of adult animals, notwithstanding numerous and careful observations on this point, we must conclude that it constitutes a later stage in the life of some other cell which has the reproductive power—and the probabilities are immensely in favor of its derivation from the leucocyte of the lymph and the blood.

The same conclusion may be drawn from considerations of another and perhaps higher character. If it be admitted that the numerous homologies of structure existing between man and the lower animals, taken in connection

with the significant facts of human and comparative embryology, throw a powerful light on man's ancestral history and on his kinships, both near and more remote, with the lower forms of life throughout the entire animal series, then the same must be admitted in regard to the origin and descent of the red-blood corpuscle. The blood of most invertebrates is colorless, its white nucleated cells resembling the earliest corpuscles of human blood. The blood-cells of the lower (the oviparous) vertebrates, though colored, are nucleated like those of human blood in its second embryonic phase. The blood of the young, also, of all mammalia (except the human) has nucleated red corpuscles, the nucleus disappearing only when the mammal has reached the adult stage, its corpuscles being then homologous with those of human blood in its third and last phase. It thus appears that the corpuscles of human blood, originating from cells of the blastoderm as colorless, nucleated, reproductive, amœboid cells, later giving rise to colored cells which still retain the nucleus, and finally appearing as fully differentiated, highly colored, non-nucleated, non-reproductive, and non-contractile corpuscles, pass through various successive stages which establish their resemblance to those of the blood of all the lower animals represented by the invertebrate, the oviparous vertebrate, the young mammalian, and the adult mammal types, reaching their full perfection about the middle of foetal life.

The leucocyte may then be regarded as the original cell-element of the blood, the hæmacyte having been specialized for the more successful performance of the respiratory function.

White blood has undoubtedly the power of absorbing a certain amount of oxygen, illustrating the general law of absorption of gases by fluids; and in those exceptional cases of colored blood in invertebrates (as in certain annelides described by Milne-Edwards in 1838, in several molluscs reported by Harless and von Bibra in 1847, and in various other groups especially investigated by Dr. Ray Lankester¹) the capacity of such blood for absorbing oxygen is undoubtedly increased by its coloring matter, since, when red, it contains hæmoglobin, and when of other colors, substances capable of acting as oxygen-carriers, some of which—notably the hæmocyanin (Frédérique) of the blue blood of the octopus—contain copper, which may be supposed to take the place of the iron in hæmoglobin. In most of these cases the coloring matter is found, not in the corpuscles, which are white, as in other invertebrates, but in the plasma, which thus adds a special respiratory to its other general nutritive functions. The fluid which circulates in the water-vascular system of the sea-urchin, and which undoubtedly serves the same purposes as the blood of higher animals, contains richly colored nucleated amœboid cells, the coloring matter of which is readily oxidizable and de-oxidizable, and therefore well adapted for respiratory purposes.

These and numerous other facts which might be cited, did time and your forbearance permit, all favor the supposition that blood is primarily a nutritive fluid which may or may not possess special respiratory power; in all the higher animals, however (beginning with the craniate vertebrates), the principle of the physiological division of labor is doubly illustrated in the blood by the differentiation of the hæmacytes for the performance of the respiratory function—a specialization of its general function of nutrition; and how well these bodies (which consist of almost pure hæmoglobin) are adapted to their work is shown by the fact that a given bulk of human blood is capable of taking up from ten to thirteen times as much oxygen as an equal bulk of water can do. That this power belongs to the hæmacytes is thrice proved: 1, By comparison with white blood; 2, by the fact that blood-serum has no greater power of absorbing oxygen than has pure water; and 3, by the fact that solutions of hæmoglobin out of the body readily combine with oxygen.

¹ A Contribution to the Knowledge of Hæmoglobin. Proceedings of Royal Society, 1872.

The avidity of the hæmacytes for oxygen is only equalled by the readiness with which they surrender it when they reach the tissue capillaries under the influence of the change in external pressure of this gas to which they are there exposed. This delicate balance of physical and chemical forces is a marked characteristic of living matter; were it not so, development and physiological progress would be impossible. Since life consists in the continuous reactions of organized matter in response to the actions of the various forces of its environment, the grade and quality of the life of any organism will depend on the sensitiveness of the matter of which it is composed. The more delicate the balance of its forces, the more ready are its reactions and the more complete its adaptations to the environment—the more assured, therefore, the continuance of its life.

Thus the hæmacytes, through the facility with which their hæmoglobin is oxidized in the lungs and the chemical instability of the resulting oxyhæmoglobin, are not only most admirably fitted for the performance of their important function, but also afford a conspicuous illustration of the living state of matter.

The blood differs, it is true, from other tissues in seemingly performing a variety of duties—the corpuscles having one office, the respiratory, and the plasma another, that of conveying dissolved and liquid nutriment to all the solid tissues, affording at the same time a means of ready escape for their numerous gaseous and other soluble waste materials; but these various offices (of which the latter may be regarded as merely incidental to the liquid character of the plasma) have a single object, viz.: the nutrition of the tissues.

A great advance was made in the principles of nutrition when Liebig's classification of foods as *plastic* and *respiratory* came to be regarded as unphysiological, and it was shown that the tissues are the seat and immediate source of all the energy, including heat, which is liberated in the body—that food, therefore, must become a constituent of some tissue before it can serve as a source of energy. The same is probably also true of respiratory oxygen, which first serves in the building up of the oxyhæmoglobin of the arterial blood-corpuscle; and the supposition that respiratory oxygen acts solely in the tearing down of tissues, thus becoming the agent in the liberation of their stored-up energy, is undoubtedly a false one.

The celebrated experiments of Pettenkofer and Voit, from which it appeared that more oxygen was consumed during sleep than in an equal number of waking hours, carbon dioxide elimination being at the same time greatly diminished, go far to prove that respiratory oxygen, like nutritive material in general, is assimilated in the restoration of exhausted tissues, especially the nervous.

Numerous observations have shown also that the activity of muscle tissue is not immediately dependent on oxidation, since excised frog's muscle will continue to contract for a considerable time in an atmosphere free from oxygen, when artificially stimulated. Not oxygen, but the *nerve-centres* supply the normal stimuli by which the energies of all the other tissues are liberated, their own energy being set free in automatic action (so-called), or through the influence of the various external forces transmitted to these centres by afferent nerve-fibres; and respiratory oxygen, in common with other constituents of the blood, is without doubt appropriated in the building up of those highly complex substances by the explosive decomposition of which the energies of both nerve and muscle tissues are liberated.

The blood has therefore, *par excellence*, a single function—that of supplying nutriment, gaseous as well as liquid, to the solid tissues; and to what extent its life-sustaining power depends on the hæmacytes is shown by the rapid occurrence of asphyxia (in three to five minutes in the dog) when their function is seriously interfered with, as well as by the facts of transfusion, since whipped blood containing these bodies retains all its restorative properties, while mere serum has no immediately reviv-

ing power; and although the importance of the plasma in nutrition must not be overlooked, the highest place (as in other active tissues) must be accorded to the fully developed adult cells—the oxygen-carrying hæmacytes.

We next inquire whether the activity of the blood, like that of the other tissues, is accompanied by waste.

That the red cells die in great numbers (finding a grave, as many believe, in the spleen) is a necessary corollary of the conclusion that the lymph-cells are being constantly converted into these bodies; otherwise, the red cells would be disastrously increased in number. The various pigments, also, found in the bile, the urine, etc., give evidence of having been derived by retrograde metamorphoses from the coloring matter of broken down corpuscles, which thus escapes in both the solid and fluid excretions. That a portion of the iron is retained in the spleen in some peculiar proteid compound¹ is probable, perhaps serving for the perfecting of the new cells which are supposed to have their birth there.

The marked chemical similarity which exists between blood and muscle, long ago procured for the former the *soubriquet* of liquid flesh. The proportions of water in the two substances are about the same, and the same salts abound in muscle-tissue, which have already been mentioned as predominating in the red-blood corpuscles. Red muscle gives the spectrum of hæmoglobin, and crystals of hæmin may be obtained from it by appropriate means (Kühne). But the researches of Kühne have disclosed other still more interesting points of resemblance, and the ultimate muscle-fibre is now described as consisting of an elastic tube, the sarcolemma, filled with liquid or semi-liquid contents, the muscle plasma, capable (like the plasma of the blood) of spontaneous coagulation at ordinary temperatures and separating into clot and serum—the process being similarly accelerated by contact with foreign matter, by whipping, etc. The myosin which constitutes the clot, though not identical with fibrin, has many properties in common with it, while the albumen of muscle-serum (the most abundant of its proteid constituents) is apparently identical with the serum-albumen of the blood.

Liberation of heat, which takes place not only during the contraction of living muscles but in rigor mortis (a state of coagulation shown by Prof. Hermann to be in all likelihood an extreme condition, of which every contraction is a partial illustration), also accompanies coagulation of the blood. There is a similar change from an acid to an alkaline reaction during the contraction and the rigor mortis of muscle and in the coagulation of blood.

Were it desired to carry the parallelism between these tissues still further, the solid doubly refracting bodies contained in the muscle-plasma—the sarcous elements, which appear under the microscope to be especially concerned in the phenomenon of contraction—might be compared to the solid corpuscles of the blood floating, in like manner, in the fluid plasma; but perhaps too little is known of the nature and function of the sarcous elements to afford grounds for an analogy, nor would it greatly strengthen the resemblance. More significant, perhaps, are the nuclei embedded in small masses of granular protoplasm, which, in the frog, may be found at varying depths in the substance of the fibre, but in mammalian muscles are generally situated just beneath the sarcolemma.

These nucleated masses of protoplasm, taken in connection with the distinctly cellular character of the more simple non-striated muscle-tissue, reveal the morphological unity existing between this tissue and all the other tissues of the body.

Kühne, in 1859, was the first to compare the amœba and the vorticella with the muscle-fibre in respect of their excitability and death changes; and the unity of the contraction exhibited by these microscopic proto-

¹ See Foster's Test-Book of Physiology.

plasmic creatures and the highly specialized muscle-tissues of the higher animals may be regarded as established.

Thus, through the hæmacyte of the blood in its amoeboid contractile stage as a leucocyte, the resemblance between these two tissues is made complete.

Before leaving this division of the subject, however, I beg your sufferance in calling attention to still another point in this analogy which involves the reference to a purely hypothetical substance—the so-called *inogen substance* of Prof. Hermann—the probable existence of which, as the result of the final synthesis of the contractile material, he offers as an explanation of certain remarkable facts, viz.: the marked increase of non-nitrogenous excretions and the equally conspicuous non-increase of *urea* which accompany muscular activity. This substance (the constituents of which in contraction are supposed to become disassociated to the extent of liberating carbon-dioxide and sarcolactic acid without the breaking down of its proteid part, which is thus spared to recombine with fresh supplies of non-proteid materials in the construction of new *inogen substance*) finds its analogue in the oxyhæmoglobin of arterial blood, which appears as reduced hæmoglobin in the venous blood, ready to reunite with more oxygen in the lungs, the previous supply of this element having escaped from the hæmacytes without further chemical disturbance of the proteid compound with which it was combined—loosely, it is true—nevertheless in a real chemical union; and the plausibility of Prof. Hermann's theory is, to my mind, greatly strengthened by this analogous phenomenon of the red-blood corpuscle.

Dr. Foster, in his valuable and charming book, for which the student of physiology can hardly be grateful enough, in introducing the subject of the blood, speaks as follows: "In regarding blood as tissue, we come upon the difficulty that it, unlike all the other tissues, possesses no one characteristic property. The receptive tissues pour into it the material which they have received from without, the excreting tissues withdraw from it the things which are no longer of any use; and the irritable, the contractile, and indeed all the tissues seek in it the substances (including oxygen) which they need for the manifestation of energy or for the storing up of differentiated material, and return to it the waste products resulting from their activity. Its real usefulness lies not so much in any one property of either its corpuscles or its plasma, as in its nature fitting it to serve as the great medium of exchange between all parts of the body."

It has already been shown (unless I overestimate the significance of the various facts cited and the importance of the arguments employed) that the differences in these numerous offices of the blood are more apparent than real; moreover, transferring our attention for a moment from the processes of nutrition to those higher phases of animal life known as sensation, emotion, volition, and thought—an equally broad and comprehensive view may be taken of the various functions of nervous tissue. Exposed through the terminations of innumerable nerve-fibres (the different varieties of which are as universally distributed among the other tissues as are the capillaries themselves) to an environment which may be indefinitely extended by the microscope and the microphone on the one hand, and by the telescope, the spectroscope, and the telephone on the other, the central nervous organs are played upon by all the forces of the external world. Changes are thereby set up in these centres, of the nature of which we know little (except that they are accompanied by the liberation of heat with elimination of carbon dioxide and other products of tissue activity), changes, however, which are capable of modifying the action of every other tissue in the body through the return threads by means of which these central organs are brought into communication with all the other organs.

Not only this, but "striking the electric chain where-with we're darkly bound," which links all sentient beings

in a common brotherhood, vibrations from these central organs thrill through the magnetic touch, sound from the vocal cords, or, more subtly still, flash from the speaking eye, and penetrate to the conscious centres of many thousands of other similarly constituted beings. Nor does nervous tissue forfeit its character as a true tissue in thus serving as a *medium of exchange* in comparison with which the exchanges of the blood seem trivial.

From every point of view, then—whether of origin and development, of structure and function, or of analogy with other tissues—the blood must be regarded as a *true tissue*; originating, in common with the other tissues, from the cells of the blastoderm; consisting, like other tissues, of structural elements and an unstructured matrix; maintaining its chemical and structural integrity by the processes of nutrition common to all tissues, and, like other tissues, subserving the interests of the organism at large through the performance of its own particular function.

A SUCCESSFUL CASE OF SPONGE-GRAFTING.

By W. G. THOMPSON, M.D.,

NEW YORK.

DURING a recent service in the Bloomingdale Insane Asylum a patient suffering from acute mania came under my charge. Several days before admission, his wife had been instructed by his physician to "blister his back with mustard." This she had done with an heroic zeal which resulted in the removal of the deeper layers of the integument at intervals over the greater part of the lumbar region! At one point, a little above the left buttock, a deep and extensive slough was formed which separated in a few days, leaving a granulating ulcer with sloping sides, $1\frac{1}{2}$ inch deep, 2 inches wide, and $3\frac{1}{4}$ inches long. As the patient's temper was none of the best, it was important that this source of irritation should be removed as speedily as possible, and I accordingly tried sponge-grafting to hasten the granulating process. Not having time to prepare the sponge by removing the silicates and cretaceous salts in the manner suggested by Dr. D. J. Hamilton, I used an ordinary fine-grained sponge, thoroughly washed, and soaked for twenty-four hours in acid. carbol., 1 to 20. From the periphery of this sponge were cut a dozen pieces from one-fourth to one-third of an inch square, which were closely applied to the floor and sides of the ulcer. The *peripheral* surfaces of these pieces were placed in contact with the ulcer, because the spiculae are larger and more branching there than in the interior, and consequently the fragments were more likely to adhere like burrs until the granulations should grow into them. The wound was cleaned with acid. carbol., 1 to 40, and powdered with iodoform. A compress was placed over the grafts and a bandage applied.

Next morning the patient had torn off the dressing, and only one graft remained *in situ*. The grafts were replaced, and instead of a bandage, broad strips of adhesive plaster were employed to secure the compress. The wound discharged pus freely, and for the first six days it was cleaned with acid. carbol., 1 to 40, and the dressing was renewed every twelve hours. After this it was only necessary to reapply the dressing once in twenty-four or thirty-six hours. Five of the grafts adhered well after forty-eight hours, and those which came away with the dressing (owing to the restlessness and interference of the patient) were replaced, so that at the end of a week the entire dozen were quite firmly adherent, and those which had been first applied could not be pulled off with a forceps without giving some pain and using considerable force. At the edges of the grafts the granulations could be distinctly seen pushing their way into the interstices of the sponges and forming little bridges from the walls of the ulcer. At the end of a fortnight the sponges had been raised to a level with the surrounding integument, and most of them had become

very much smaller, while one or two seemed to have been completely absorbed.

After three weeks the ulcer had almost entirely healed, and the grafts which had not become absorbed or dissolved, perhaps in part by the pus, were gradually removed with scissors as the skin grew inward to meet them.

From the situation of the ulcer and the restlessness of the patient, who was constantly walking about, it would have been impossible to maintain the grafts in position had they not early become very firmly attached.

The granulations sprouted up with such vigor that one could almost see them grow, and the healing was no doubt completed in less than half the time that would have been required without the support and stimulus afforded by the grafts; and had the sponges been elaborately prepared, the result could not have been more satisfactory.

DEATH FROM VACCINATION.

By HORACE M. SIMMONS, M.D.,

BALTIMORE, MD.

IN view of the universal interest which must attach to such a subject, I avail myself of a little space in the columns of your wide-spread journal in reporting a case of death superinduced by vaccination. The extent to which small-pox prevailed in our city during the past winter, requiring the most prompt and energetic measures to suppress it, afforded ample opportunity for observation and experimentation in proving the efficacy of vaccination as a prophylactic. No sooner had general compulsory vaccination been inaugurated than the ravages of the disease began to abate. During the prevalence of small-pox in this city in 1873 similar measures were instituted with equally apparent results. Other cities have had a like experience. It would seem that such incontrovertible evidence should convince the most skeptical; nevertheless, there are those among us who deny the efficacy of vaccination as a prophylactic, and denounce it as a most pernicious practice, the outgrowth of barbarism and superstition. The occurrence of so unfortunate a case as we are about to relate only affords the opposition element more plausible grounds for their arguments, and makes them more bitter in their denunciations.

In the discharge of my duty as a city vaccine physician, I visited the house of Michael R—, and vaccinated all the inmates whom I did not deem sufficiently well protected from previous vaccinations. The date of this occurrence was January 20th. On February 23d, on my second visit to this locality, I repeated the operation where it had not been successful in the first instance. Among the number was a white female infant nine months old, apparently in perfect health, whose arm bore no signs of the previous operation. Accordingly I repeated it, using this time the National virus which I had obtained from the Health Department. The operation was performed in the usual manner, by making the abrasion about one-sixth of an inch in diameter, with the pointed end of the quill, without drawing blood. (I would state here that I did not follow these directions in every instance, as sometimes I would make the abrasion much more extensive. But I never employed the lancet while using either the National or Chelsea virus, both of which were furnished us by the Health Department; nor did I use the same point a second time.) Nothing unusual was noticed until the ninth day after the operation, when the child became fretful and showed signs of fever, accompanied by swelling of the lymphatic glands of the neck and axilla. Simultaneously, a measles eruption developed over the abdomen and extremities. The arm appeared to be paralyzed, and was somewhat swollen, especially in the region of the axilla, while the skin presented a rough, chafed appearance, and was dotted with ecchymosis extending almost to the hand.

The scab had assumed a dark reddish hue, with contracted margins and depressed centre, and did not present the characteristic appearances of a genuine vesicle. The contiguous glands, together with the parotid and submaxillary, became involved, and showed signs of suppuration. Convulsions supervened, with an aggravation of all the other symptoms, on the third day of the attack, being the twelfth after the operation, and the child died on the thirteenth day.

No constitutional taint could be discovered in the parents or grandparents, all of whom are living and in good health. The peculiar circumstances attending this case render it difficult to account for the unfortunate result. This is the first case known in medical annals where a child has died of vaccination in Baltimore. In my daily rounds as vaccine physician, numerous instances were recounted to me by the laity in which they attempted to depict the horrors of vaccination. I discredited these reports, believing them to be fabrications devised by those who deny the efficacy of the Jennerian method, or who wished to oppose it from some other point of view. Upon further investigation, however, I have derived information from authentic sources, showing conclusively that vaccination is by no means free from danger. I shall not encroach upon your valuable space in relating the details of cases, but suffice it to say that the principal abnormal deviations consisted for the most part of erysipelas, pyæmia, gangrenous ulcers, suppurations, glandular involvements, eruptive disorders, etc.; though, perhaps, some of these complications may have occurred coincidentally, and not as the result of vaccination. The operation may have acted only as an exciting agent in arousing a latent predisposition to the disease. On the other hand, cases have occurred, no doubt, where the disease was on the point of outbreak, and not the result of any exciting cause. The following instance is recorded: For some reason a proposed vaccination was postponed; in the interval the infant developed an inherited syphilis. In this case, as in all other troubles that happen to appear after vaccination, the parents would have been only too happy to avail themselves of a convenient scapegoat for their own infirmities.

As to what may be regarded the most formidable complication following the operation of vaccination, I am unable to say from personal experience. *Apropos* to the subject, however, I shall quote briefly from a few eminent authorities. In Hardaway's "Essentials of Vaccination," erysipelas is spoken of as a comparatively rare although one of the most serious complications of vaccinia, or rather of vaccination. Dr. Ballard makes a wise distinction between erysipelas *after* vaccination and erysipelas *from* vaccination. He points out that the disease may occur as a consequence of the prevalence of general erysipelas, or may be due to sanitary defects in the house of the patient. Dr. J. Lewis Smith observes that the vaccination acts often merely as an exciting cause, not from any deleterious property in the virus itself, but just as an equal degree of inflammation might be produced from a cut, burn, or other indifferent agency. On the other hand, the virus itself may be the direct exciting cause. Vaccinal erysipelas may commence immediately after the operation, or it may wait upon the development of the vesicle, or be delayed until the fall of the crust.

Excluding those cases of erysipelas in which the vaccination has been merely an accidental factor, it is stated that the disease is prone to occur from use of revaccination lymph, from spurious primary cases, or from lymph taken at too late a period of the vesicle, or, finally, from lymph which has become partially decomposed. The course of the vaccine vesicle is sometimes interfered with by mechanical influences, such as scratching, rubbing of the clothes, etc. The inflammation under these circumstances is apt to be increased, and suppuration may occur. The scab which results is composed of large yellowish crusts unfit for use in vaccination. Inflammation and suppuration of contiguous lymphatic glands are some-

times an annoying, although not generally a serious, complication. Hebra states that occasionally swelling of the parotid and submaxillary glands occurs after vaccination, attended with rather abundant salivation. In children of a vitiated constitution, when the inflammation surrounding the vesicle has been intense, circumscribed abscesses may occur. Mr. Savory reports a case of pyæmia following about the ninth day after vaccination which resulted in death. Dr. Day records the case of a patient who had wasting of the deltoid and paralysis of the arm, which he regarded as consequent upon vaccination.

The foregoing facts would lead us to the conclusion that we may reasonably expect, as *unavoidable*, a small percentage of mortality, with other untoward results, consequent upon the operation of vaccination. In view of this fact, it behooves us, as intelligent and faithful physicians, to exert our utmost endeavors in combating and overthrowing those wide-spread notions which are the outgrowth of skepticism and incredulity, and which are so prejudicial to the cause we espouse and to the well-being of human-kind. It is only through a more extensive dissemination of knowledge upon this subject, derived from a careful observation of facts, that we shall be able to refute those absurd theories which have already gained favor with the unenlightened. Such incontrovertible evidence is needed to restore the confidence of the wavering, and to disabuse the public mind of those preconceived and unwarranted conclusions which have been so universally propagated by the opponents of vaccination.

558 WEST FAYETTE STREET.

A CASE OF PARALYSIS OF THE ARM, FOLLOWING VACCINATION.

By J. H. POOLEY, M.D.,

PROFESSOR OF SURGERY IN THE TOLEDO MEDICAL COLLEGE.

EUGENE S—, German, married, aged twenty-two. He is a finely developed, athletic young man, and has always been perfectly healthy.

On August 5, 1880, he was vaccinated on the left arm at the usual situation, the insertion of the deltoid muscle, with the so-called bovine virus. A large number of persons—about fifty—were vaccinated at the same time, and with the same virus, in none of whom did any untoward results follow.

S— had a very sore arm; the vaccine pustule became a large, deep ulcer, with a wide-spreading areola of dusky redness, indurated, painful, and tender.

The lymphatics in the axilla were exceedingly painful, and enlarged to such an extent that it was thought at one time they would inevitably suppurate. He had also pretty severe constitutional reaction, with high fever and slight delirium.

About September 1st, when both the local and constitutional symptoms were decidedly on the decline, he got up one morning and found his left arm completely paralyzed. Though he had formerly been in the habit of sleeping with this arm thrown up under his head, he had not, of course, done so for some weeks, owing to its painful condition.

I first saw him on December 1, 1880; his condition then was as follows: The left upper extremity was still perfectly paralyzed. When lifted up, and then let go of, it dropped to his side like a lifeless and inert mass; he had not the slightest power to move it, nor any part of it, not even a finger. There was also complete anæsthesia and analgesia; he could not tell when it was touched, or distinguish between ice and boiling water. A pin thrust into the limb, or small incisions, were entirely unnoticed.

This anæsthetic region extended completely up the arm, and quite up to the top of the shoulder, also over the pectoral region half-way to the sternum, and behind

as far as the spine of the scapula, ending quite abruptly at these points. The limb continued to be well-nourished, not even measurement showing any difference in the size of the two arms, but I thought the muscles were decidedly flaccid and deficient in tone.

I could detect no difference in the pulsation on the two sides, and the temperature was the same in both axillæ. The electrical excitability of the paralyzed muscles was good. The vaccination sore had been well some time, there was no enlargement in the axilla, and his general health was first-rate. The palm of his left hand was constantly wet with perspiration, even in the coldest weather, while the other was quite dry; there was some of the well-known "glossy-skin" appearance about the fingers, but no causalgia, or pain of any kind. A few herpetic or eczematous vesicles were distributed about the roots of the nails.

He had no pain of any kind, anywhere, when I saw him, but had previously had, in addition to that caused by his sore arm and axillary swelling, darting, lightning-like pains the whole length of the limb, together with tingling and pricking sensations.

I advised the hypodermic use of strychnine into the paralyzed arm, in gradually increasing doses, till some toxic effects were produced, together with massage, and faradic electricity.

I saw no more of him till about a year afterward, when I met him accidentally, and found that he was quite well, and had been for some months; he said that he began to improve soon after I first saw him, and attributes his recovery mainly to the electricity.

This is certainly a very interesting case, and perhaps not quite easy of interpretation, though my own opinion was, and is, that it was a neuritis of some of the nerves of the axillary plexus, perhaps all of them, brought about by pressure and extension of inflammation from the enlarged lymphatics.

The entire absence of more grave general symptoms, and the peculiar phenomena of the sweating palm, glossy skin, and vesicles about the nails, seem to me to establish the diagnosis. As to the treatment, we must not forget the element of time, and very likely he would have recovered with this alone, but what we did was at any rate in the right direction, and could do no harm.

TOLEDO, O., May 18, 1883.

SUTURE-CLAMP COAPTATION.

A NEW METHOD FOR CLOSING WOUNDS.

By J. H. CIPPERLY, M.D.,

MEDICAL ASSISTANT, MARSHALL INFIRMARY, TROY, N. Y.

To the means ordinarily employed in repairing a lacerated or incised wound—bandages, adhesive strips, surgical pins, and the various sutures—another, a new and facile method, is obtained with what I am pleased to call, in the want of a better term, a suture-clamp. Made of hard silver wire, bent at acute angles at both ends, the extremities of the arms sharpened to a point, the instrument is pictured thus:

One hand supports the severed parts together, while the other introduces a clamp, penetrating one lip at a time, and introducing a clamp at regular distances until the coaptation is complete. Their position is retained by the tight grasp of the skin and tissues on the arms of the clamps, supplemented by the inclination of the arms toward each other. A moment's consideration of the advantages of this method: the most striking are the ease and rapidity with which you close the wound. A single instrument is all there is at hand; you do away with needle, wire, needle-forceps, scissors, and the trouble accompanying them. In the closure of the wound there is less constriction to the lips than results in the use of

sutures or pins, where the swelling often causes a tearing out; thus is aided the better work of repair. The arms of the clamp sustain both walls, so that the deeper parts of the wound conjoin, and there is less opportunity for the pocketing of blood and pus, and more rapid healing. Again, there is the minimum of pain attending their introduction and they are removed without pain, and may be used again. Made of various sizes (usually required but three or four), their application is general. With short arms they may be used in scalp wounds and over bony places. In wounds where there is contusion and laceration and gaping, long clamps reaching across will produce a partial union at least, otherwise not attained. The first application was made in the case of an injury where the toes and portions of the metatarsal bones were removed, a buzz-saw accident leaving a single flap from the plantar surface of the foot, and rather short to cover the exposed bones. Five clamps were applied that closed the wound, and were allowed to remain six days, when adhesive plaster was brought into play, as the wound was healing by granulation. In this first instance their ready, time-saving usefulness was at once clearly demonstrated. This occurred in March, 1882, and I have since made use of them repeatedly, and with the uniformity of repeated satisfaction in their success.

Suture-clamp for wounds.—I. Is a new method.

II. Is made of hard silver wire by preference.

III. Has advantages: 1, Of rapidity in application; 2, of a single instrument at hand; 3, of less constriction; 4, of better coaptation; 5, of but little pain on introduction and removal; 6, that it may be used again; 7, of partial union in gaping wounds.

IV. First used in March, 1882.

DOUBLE IDENTITY AFTER TREPANNING.

By J. N. McCORMACK, M.D.,

BOWLING GREEN, KY.,

PRESIDENT OF THE KENTUCKY STATE MEDICAL SOCIETY, AND MEMBER OF THE STATE BOARD OF HEALTH OF KENTUCKY.

C. W.—, an American farmer, aged twenty-three years, was brought to me in March, 1881, for examination as to his mental condition, that I might testify before a jury, which his friends had requested, as they desired to send him to a lunatic asylum. He was brought from the country in an open wagon by his wife and two friends, and from them was learned the following history: When fifteen years of age, and while engaged as a "striker" in his father's blacksmith-shop, he was struck on the head with a pointed hammer and felled to the floor, was unconscious for several hours, gradually recovered, and after a few weeks, suffered no noticeable inconvenience from the injury, although a marked depression of the skull remained. This occurred in Allen County. Two or three years later he came to the community in which he now resides, was married when nineteen years of age, purchased a farm shortly afterward, and all this time presented no mental peculiarity which was sufficiently marked to attract attention. Six months before he was brought to me he began to complain of pain and tenderness in the seat of the old wound, and about the same time began to exhibit indications of mental derangement. At first he was morose and sullen, but later became maniacal and difficult to restrain, and for several weeks had had no lucid interval. He had eaten but little, his sleep had been much disturbed, and he had lost strength and flesh rapidly. At the time I saw him he was emaciated and cachectic in appearance, with furred tongue; pulse, 110; temperature, 98°. He was very nervous and impatient of restraint, and presented all the symptoms of acute mania. There was a deep depression, about the size of a silver quarter, at the junction of the sagittal with the coronal suture, and the scalp in the vicinity of the depression was so sensitive that it was examined with great difficulty. The man was

evidently in no condition to be sent to an asylum, and was returned to his home a short distance in the country.

On the following day the operation of trepanning was performed in the presence of Drs. Porter, Murray, Neale, and Meredith. At first a section of bone was removed with a large trephine, and as this did not include all the internal depression, a second section was taken out which slightly lapped into this; still a corner remained, which was removed with bone forceps. The membranes were not injured, and the dura mater appeared healthy. The wound was closed, except at the posterior part, which was left open for drainage. The recovery was rapid, and the relief of the mental derangement was immediate and permanent. He gained strength and flesh rapidly, and in a few weeks appeared to be in perfect health.

Immediately following the operation were developed those curious mental phenomena which gave special interest to the case. The man seemed to be impressed with the idea that he had just recovered from the effects of the blow on the head, and although he talked freely of his history up to the time of the accident, seemed to have no recollection of any event of his life from this time until he was relieved by the operation. He said that he did not know his wife, or that he had a wife; his neighbors were strangers to him, and his business transactions in connection with the purchase of his farm could only be understood after an examination of the deeds and full explanation. He seemed to be entirely ignorant of his former surroundings, and had to learn the roads of his neighborhood like any other stranger. Some of his friends were sceptical in regard to these things, and many tests were made of their truth. His answers were frank and candid, and he always said that he was totally unable to recall anything occurring in this period of his life. When it is remembered that while a man of fair intelligence, that his education was very limited, and that he had never heard of a similar case, it is more difficult to believe that he could manufacture and be consistent in such a story than to believe the story itself. His friends all concurred in saying that there had been a marked change in his general demeanor since the operation. While always industrious and sober, he had been rather boisterous and turbulent in disposition, which was in striking contrast with his quiet manners since the operation. It is to be regretted that the man was not highly intellectual and accustomed to describing his methods of thought, as the interest of the case would be greatly increased by minute mental details.

GONORRHEA OF THE RECTUM.—Thiry (*Presse Méd. Belge*) believes in the reality of gonorrheal inflammation of the rectum, an affection which is not recognized by many authors. In support of his opinion he relates the following case: A woman, aged twenty-four, a clandestine prostitute, was admitted into the Hôpital St. Pierre, Brussels, complaining of weight and shooting pain in the pelvis, pain in defecation, and a constant thick discharge from the bowel. Walking also was difficult. On examination, there was a well-marked funnel-shaped depression of the anus, the anal folds were obliterated, and the sphincter was weak and dilated. A vaginal speculum of ordinary size passed easily and without causing pain. On washing away the abundant thick discharge, the lower portion of the rectum was seen to be acutely inflamed and studded with bright red points, which bled when wiped with wool. The follicles in the rectal folds were enlarged and discharged pus. The patient confessed that she had had relations with men who were suffering from clap. Solution of borax was used locally at first; afterward red cinchona bark was applied to the mucous membrane, and, finally, an injection of oak-bark was used. Under this treatment, combined with sitz-baths, and the internal administration of iron, the woman recovered in about three weeks.

Progress of Medical Science.

PECULIAR DISTURBANCE OF THE CAPILLARY CIRCULATION.—At a recent meeting of the Harveian Society, Dr. Broadbent showed a patient who was suffering from a peculiar disturbance of the capillary circulation. Eight years ago he had a sunstroke, which for a time rendered him insensible; previously to this, he had frequently suffered from pain in the occipital region and vertigo, which since that time had been much aggravated. Seven weeks ago, while looking over a bridge, he was seized with a sudden and violent pain in the back of the head, and intense giddiness, upon which supervened unconsciousness, lasting for fifteen minutes; since that time he had had many similar attacks, as many as three or four a week. He was a man aged forty-six, somewhat deaf, and with a confused manner when spoken to. The patellar tendon reflex was increased, especially on the left side, ankle-clonus was absent; there was slight loss of sensibility in the lower extremities. On speaking to the patient a blush appeared on the face, which extended over the chest and back, and lasted several minutes, leaving a mottling of the skin which somewhat resembled roseola. The *tache cérébrale* was unusually well marked, a line of vivid redness appearing in the track of the finger-nail drawn over the skin; myoidema was also present, though not in so marked a degree as when the patient first came under observation. Dr. Broadbent stated that this was a condition occasionally seen when the nervous system was broken down by overwork and strain. The *tache cérébrale* was most frequently seen in tubercular meningitis, but it was often present in other acute cerebral diseases, and sometimes in enteric fever; its recurrence in association with prostration of the nervous system without fever was interesting. He was reminded of cases in which artificial urticaria could be produced by very slight irritation, but he had seen this in robust health, and it appeared to be congenital. Myoidema was most common in phthisis, and in the late stage of enteric fever, and was generally indicative of wasting under fever. In the case before the meeting, however, there was no history of any febrile condition. It might possibly have been due to insufficient food, which, during the siege of Paris, had given rise to myoidema on a large scale. Dr. Broadbent had once seen this condition in a single muscle, the right trapezius, in a case of aneurism of the aorta.

ARE PHTHISIS, BRONCHITIS, AND PNEUMONIA EPIDEMIC DISEASES?—At the last meeting of the Epidemiological Society (*British Medical Journal*, April 21, 1883), Dr. Longstaffe presented an interesting report touching the above question.

The author explained that his object was to examine the Registrar-General's returns in such a way as would make clear their bearing on the solution of the question propounded. As in previous papers relating to summer diarrhoea and the diseases allied to erysipelas respectively, he exhibited diagrams graphically representing the death-rates for England and Wales from the diseases in question, and certain others in various ways allied to them, during a period of twenty-five years. He also showed the same death-rates in London for thirty-three years, compared with a curve expressing the number of cold days in each winter. One diagram showed that the death-rate curve of phthisis deviated very little from a straight line, resembling in this respect those for cancer, apoplexy, paralysis, convulsions, and fractures. The curves of tubercular meningitis, and to a less degree *tabes mesenterica*, resembled the phthisis curve. The death-rate from phthisis had fallen twenty per cent. during the last twenty years. The bronchitis curve exhibited considerable fluctuations, but, on the average, it had risen eighty-one per cent. during twenty years. Pneumonia gave a curve closely resembling that of bronchitis in many respects, but the average mortality had fallen twenty per cent.

The total mortality from all diseases of the respiratory organs, together with phthisis, showed an increase of five per cent., indicating that probably many deaths formerly returned as due to phthisis or pneumonia were now classed with bronchitis. Pleurisy appeared to be more allied to rheumatism than to respiratory diseases. From the curves relating to deaths in London, it appeared that bronchitis and pneumonia corresponded with the coldness of the winters, but not so closely as might have been expected. Phthisis was but little affected. Curves derived from Messrs. Buchan and Mitchell's paper on "The Influence of Weather on Mortality," showing the average weekly fluctuations of the death-rates from various causes in London during thirty years, strongly confirmed the author's conclusions, with the single exception of *tabes mesenterica*, which gives an entirely different curve from that of phthisis. In another diagram were exhibited the weekly fluctuations of the deaths from bronchitis and pneumonia during the last five winters in London, and their relation to cold; also the same for phthisis during two of the winters. This diagram showed clearly that the death-curve of pneumonia had a general correspondence with the death-curve of bronchitis; but it differed in two particulars: the fluctuations were much less, and while it rose in the autumn as rapidly, it fell in the spring more gradually. The author's main conclusions were these: 1. The mortality statistics of England and Wales did not give any evidence in favor of the view that phthisis is communicable; but they showed, on the other hand, that weather had very little influence on the death-rate of phthisis. 2. While bronchitis and pneumonia were both greatly influenced by meteorological conditions, it was difficult to explain by those conditions only all the phenomena. 3. Common catarrh was a communicable disease; and it was probable that very many cases of bronchitis and pneumonia might be looked upon as complications of that or some similar disease of mild character when uncomplicated. 4. The different incidence of bronchitis and pneumonia on the two sexes pointed to some difference in the causation of the two diseases. 5. There would appear to be some common factor in the causation of phthisis and tubercular meningitis.

A NEW SIGN OF PREGNANCY.—Dr. Jorissenne claims to have discovered a new and certain sign of pregnancy, even in the first months. It consists in an unchanging frequency of the pulse, in the three positions of standing, sitting, and lying. Normally, the pulse-rate varies in these three positions, but in pregnancy, even at the first month, this variation is not observed. The same condition, he states, is observed only in cardiac hypertrophy. Other changes in the genital apparatus, such as tumors, are not marked by this phenomenon. An explanation of this peculiarity is thought by the author to be either in changes in the blood, producing disturbances of the circulation, or in hypertrophy of the heart. The latter is asserted to be a physiological condition in pregnancy by many authors, but denied by others.—*Deutsche Medicinal-Zeitung*, March 8, 1883.

ERGOT AS A PREVENTIVE OF THE POISONOUS EFFECTS OF SALICYLIC ACID.—Dr. Schilling recommends the administration of ergot in conjunction with salicylic acid or quinine, to obviate the unpleasant effects of those drugs. He had observed, in a number of cases in which large doses of salicylic acid were taken, a marked congestion of the external auditory canal and *membrana tympani*. He was thus led to give ergot to cause a contraction of the vessels, and obtained in every case a cessation or notable diminution of tinnitus and deafness. The dose of ergot (aqueous extract) should be about one-tenth that of the salicylic acid. The antipyretic effect of the latter is not weakened by the ergot. Like favorable results were obtained by combining ergot with quinine.—*Allgem. Med. Central-Zeitung*, March 21, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, May 26, 1883.

THE ACTIONS AND USES OF ATROPIA.

ONE of the physiological effects of atropia is diminution or arrest of various secretions. Thus dryness of the mucous membranes of the throat, mouth, and nares has been noted after the ingestion of this drug. The secretory function of the skin is also suspended. Therapeutics has taken advantage of this moderating action on secretion. Thus, in the treatment of coryza, Dr. Gentilhomme, of Geneva, taking his departure from the fact that atropine diminishes the secretion, even causes dryness of the nasal mucous membrane, prescribes pills, containing each one-half milligramme of sulphate of atropine. At the onset of the coryza one pill is taken, and in an hour's time the sneezing will have ceased, the secretion will have disappeared, and the respiration become free. Sometimes a quarter of a milligramme ($\frac{1}{40}$ grain) is sufficient to produce this result. In chronic bronchitis the same favorable result has been obtained. In profuse salivation, from mercury, pregnancy (reflex salivation), etc., Gabler has derived benefit from atropine in minute doses; he prescribes powders of atropine, containing each one-quarter of a milligramme rubbed up with white sugar; one powder may be taken every four hours till the physiological effects of the drug are experienced.

This same authority has prescribed atropine with success in catarrhal diarrhœa, giving from one-fourth to one-half a milligram every five hours till toxic manifestations appeared. There is, perhaps, no better remedy with which to combat the profuse night-sweats of phthisis. As an anhydrotic it has a high place in the practice of physicians all over the world. Dr. J. Milner Fothergill recommends doses varying from the seventy-fifth to the fiftieth of a grain. Vulpian ("Clinique Méd.," p. 338) advises pills of sulphate of atropine, each containing one-half milligramme. Of these, two pills, one hour apart, in the evening. If this is not sufficient, give another about the middle of the afternoon. It is rare, he says, that more than three pills a day are necessary.

Bartholow, who prefers atropine to any other remedy for night-sweats, is much in the habit of prescribing a pill of $\frac{1}{20}$ of a grain three times a day; besides acting as an anhydrotic it facilitates respiration.

That well-known sedative action which atropine exercises on the peripheral terminations of nerves, and on the elements of the nerve-centres, may, irrespective of any supposed constrictive effect on the vaso-motors—which is an effect by no means constant—explain the use of

this medicament in affections of the cerebro-spinal nervous system characterized by phenomena of excitation, such as pain, spasm, convulsions, epilepsy. By this sedative action Gabler (also Trousseau and Pidoux) account for the remedial efficacy (so often noted) of belladonna and its alkaloid in rheumatismal and other inflammations of the spinal cord and its membranes. Under the influence of this drug, the pain and numbness and contracture of the extremities often give way rapidly.

In nocturnal incontinence of urine, atropine, by allaying irritability of the muscular fibre of the bladder, or producing stupefaction of the mucous membrane of that viscus (eminent authorities, as Gabler, believe that both effects are brought about as the result of the physiological action of the drug) proves an invaluable remedy. One grain of sulphate of atropine may be rubbed up with one hundred grains of white sugar and divided into a hundred powders. Of these, one may be taken at bedtime by a child twelve years old. Or one drop may be given at bedtime of the solution of sulphate of atropine of the British Ph., which consists of two grains sulphate of atropine to half a fluid ounce of distilled water. If this should be inefficacious, the second night two drops of the solution may be administered, which will, without doubt, give the physiological effect of the medicament. The dose must gradually be increased according to the necessity of the case.

In pertussis, one of the best remedies is sulphite of atropia, and, given according to Bartholow's formula, it is sure to give relief in the spasmodic stage where there is profuse bronchial secretion. One grain of sulphate of atropine is dissolved in an ounce of cherry-laurel water; of this two drops may be given three or four times a day. We have used this remedy with advantage in whooping-cough in the form of spray; the liquid in the atomizing cap of a spray-producer or steam atomizer being charged with five drops of Bartholow's solution. Atropia has a remarkable sedative or stupefying effect in irritable nerve-terminations when applied locally, and the quantities of the medicament that may be used with benefit are really infinitesimal. The above solution makes a good liniment in painful neuralgias, but must not be rubbed about the orbit for obvious reasons.

These are some of the uses of this valuable medicament. We have not referred to its use as a local anodyne and mydriatic in ophthalmic practice; probably no drug is in higher repute with ophthalmologists.

Properly managed, there is scarcely a remedial agent in the *Materia Medica* that will be of such real service to the physician, but it needs to be used with great care and judgment.

TRANSFERRED IMPRESSIONS AND "TELEPATHY."

ALMOST every physician, during the course of his professional life, hears stories regarding clairvoyance. Some individual has had a vision or dreamed a dream which is subsequently found to have represented, most marvellously, actual objects or persons that were at the time far away.

An organization in London has been investigating the alleged phenomena of this class, endeavoring to apply scientific methods to their study. The *Nineteenth Century* and the *Fortnightly Review* have at different times

published some of the results of this work. Quite recently the latter journal has published an article by Mr. Edmund Gurney and Mr. Frederick W. M. Myers, claiming very positively that the mind may at certain times be capable of receiving impressions through other channels than those of the various senses; in other words, that the so-called *clairvoyance* is an actual physiological fact. The phenomenon is described as a transference of impression, and is somewhat different from thought-reading, no evidence being here given that a train of ideas or an intellectual process can be thus "transferred."

The authors in question have collected a large amount of what they consider evidence for their view, this evidence consisting in stories told to them by persons whose character they in most cases have investigated.

The number of these stories is, we are told, enormous, and they all tend to prove the same thing, so that even if singly they might be doubted, collectively their weight as evidence is overwhelming.

In describing the phenomena certain technical terms are adopted. The person who receives the impression is called the percipient, the person who causes it, the agent. Now it is found that when the transference takes place, one or other of the persons is generally in an abnormal or unconscious condition; *e.g.*, in a state of trance or of sleep, or at the point of death, or under the influence of some powerful emotion. The cases are therefore classified in accordance with the condition of the agent or percipient. As an example of the class of phenomena alleged to be real we append the following:

"One Sunday night last winter, at 1 A.M., I wished strongly to communicate the idea of my presence to two friends, who resided about three miles from the house where I was staying. When I next saw them, a few days afterward, I expressly refrained from mentioning my experiment; but in the course of conversation one of them said, 'You would not believe what a strange night we spent last Sunday,' and then recounted that both the friends had believed themselves to see my figure standing in their room. The experience was vivid enough to wake them completely, and they both looked at their watches, and found it to be exactly one o'clock.' (One of these friends has supplied independent testimony to this circumstance.)"

We have ventured to furnish our readers this account of the work of these gentlemen because of the strong endorsement that has been given to it, and because of its important physiological and pathological significance. If it could be proved that the mind can perceive through other agencies than the senses, it would establish a fact which would antagonize the present physiological theories (based upon evolution) of the development of these senses; for it is now believed that they were developed in order to enable the animal to adapt himself to his environment. They were made *by* the environment primarily, rather than *for* it, and in the history of animal evolution there are absolutely no data which enable us to account for the development of a supersensual perceptive power.

The evidence collected by Messrs. Gurney and Myers is not of the kind, as so far presented, to bring positive conviction, despite their positive claims. The stories,

many of them, are second hand; they are for the most part told by women, and sometimes by children. Some of them were first narrated a hundred years ago. The element of unconscious exaggeration appears to be taken but little into account. Furthermore, the possibility of coincidence is of itself almost enough to explain them. Thousands upon thousands of dreams and visions, impressions and presentiments are occurring constantly. We hear from those which turn out to be true, but not from the others. Despite all this, however, the inquiry is a most interesting one, and if it finally ends in explaining in any way the extremely numerous stories of thought-reading and clairvoyance, a large element in the world's uneasiness will have been removed.

News of the Week.

THE ANNUAL MEETING OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS—DONATION OF TEN THOUSAND DOLLARS.—The Cartwright Prize of five hundred dollars of the Alumni Association of the College of Physicians and Surgeons of this city, was awarded to Dr. Walter Mendelsohn, for an essay entitled: "Circulation in the Kidney during Fever." The experiments upon which the essay was based were performed at Leipzig under the direction of Cohnheim. It was voted to advertise the Cartwright Prize more extensively in the future, for the purpose of securing more and better competing essays.

The president announced that Mr. James T. Swift had given, under certain conditions, the sum of ten thousand dollars to the association as a fund for the purchase and care of physiological apparatus, to be used by and under the care of the professor of physiology of the college. The sum is given on condition that the college secure a new building in which shall be a suitable room for the apparatus in question. The fund is established in memory of Mr. Swift's brother, the late Dr. Foster Swift, formerly assistant professor of obstetrics in the college.

The Alumni Association now possess six different funds for various objects. Three of them amount to about ten thousand dollars, and one to nearly twenty thousand dollars. It is, therefore, probably the richest association of the kind in the country. Effort is being made to increase the fund for the support of the physiological and pathological laboratory. Most of the work in this laboratory is that of elementary instruction in histology and morbid anatomy, and it is to be regretted that it does not or cannot offer opportunity for higher scientific labors.

The association re-elected its present officers.

THE MOSES TAYLOR HOSPITAL.—The work on the new Moses Taylor Hospital, which is to be built on an eminence overlooking Scranton, Pa., on ground given by the Lackawanna Iron and Coal Company, is to be begun about June 1st, under contracts based upon plans made by Mr. Carl Pfeiffer of this city. A group of buildings in the Queen Anne style has been planned to cost \$300,000. It is expected that Mr. Percy D. Pyne and the heirs of the Taylor estate will add \$200,000 to the endowment fund given by Moses Taylor, and it is ru-

mored that the Delaware, Lackawanna and Western Railroad Company, and the Lackawanna Iron and Coal Company will arrange to further increase the endowment by \$1,000,000.

REGULATING THE PRACTICE OF MEDICINE IN MINNESOTA.—We have received a copy of the law which has recently been enacted regulating the practice of medicine in Minnesota. It provides that the Faculty of the Medical Department of the Universities of Minnesota shall organize as a Board of Examiners. All persons who practise medicine in the State must present their diplomas to this Board for verification, or if they have no diploma must submit to examination in order to receive a license.

There is nothing said regarding the character of the diploma, which presumably need only be a medical diploma from a medical college of any kind.

A DOCTOR WITHOUT A LICENSE.—Dr. O. C. Gage, who was arrested at Dover, N. H., for practicing medicine without a license from a New Hampshire medical society, has been discharged without costs. The defendant showed that a license was refused him only because he advertised in papers and did an itinerant business.

The inference is that the laws against charlatany in New Hampshire are very weak.

QUARREL AMONG THE JOHNS HOPKINS TRUSTEES.—A minority of the Trustees of the Johns Hopkins University, led by Mr. Garrett, have published a circular stating that the funds and work of the University have not been properly directed. It is claimed that the buildings should be erected at Clifton, outside the city, also that too much money has been spent in salarizing professors. These charges are denied.

DISEASE IN CONNECTICUT.—The April report of the State Board of Connecticut shows an increase in respiratory and malarial diseases. Measles is quite prevalent. One case of small-pox occurred not long ago.

THE DEATH OF DR. BENJAMIN WILLS RICHARDSON, of Dublin, is announced. Dr. Richardson was a physiologist and histologist of high repute. This is not Dr. Benj. Ward Richardson, of London, who is perhaps more widely known.

FIRE IN THE HARVARD MEDICAL SCHOOL'S NEW BUILDING.—A fire took place in the new building of the Harvard Medical School recently, but it was confined chiefly to the amphitheatre, the building being fire-proof. The damage amounted to about \$2,000, which does not fall on the college, as the building had not been handed over to the trustees.

NEW INSANE ASYLUMS.—Geneva, Ill., has appropriated \$12,000 to erect a county insane asylum; also Racine, Wis., is going to have an insane hospital.

DR. W. E. QUINE, one of the ablest professors of the Chicago Medical College faculty, has resigned his chair.

REMOVAL OF THE UNITED STATES MARINE HOSPITAL AT BEDLOE'S ISLAND.—The temporary buildings on Bedloe's Island, now used as a United States marine hospital, being insufficient for the purposes required, the hospital authorities have leased the Seamen's Retreat at

Stapleton, Staten Island, from the Marine Society. A few alterations will be necessary in the new quarters, but in most respects the buildings at Stapleton, which are of stone, are greatly superior to the temporary ones on Bedloe's Island. The grounds of the Seamen's Retreat are very fine and extensive, and have a large water front.

FORBIDDING THE SALE OF TOBACCO TO BOYS.—The New Jersey State Legislature has passed a law forbidding any person, knowingly, to sell cigarettes or tobacco in any form to any minor under sixteen years of age.

Reports of Societies.

CONNECTICUT MEDICAL SOCIETY.

Ninety-second Annual Convention, held at Hartford, Conn., May 23 and 24, 1883.

(By Telegraph to THE MEDICAL RECORD.)

THE Ninety-second Annual Convention of the Connecticut Medical Society was held at the City Hall, Hartford, Wednesday May 23d, commencing at three o'clock.

The President, DR. WM. G. BROWNSON, after welcoming the Society and alluding to the results they should endeavor to achieve, presented the following suggestions for consideration.

PRESIDENT'S ADDRESS.

That a committee should be chosen to report on the legal status, and a revision of the charter and by-laws, the term of office of the Secretary, which should be permanent, and like topics. A board of councillors was advised, to be made up of all ex-presidents, who should be a board of censors also, and procure suitable literary exercises, etc. An increase of fellows was advised to correspond with the increased membership of the Society. He announced, with regret, that from press of other duties Dr. Chamberlain could not longer serve as secretary, and spoke of the prosperity of the Society during his eight years' service; notwithstanding the loss of eighty-five members by death, the Society had gained over a hundred members, and the balance in the treasury had never been more satisfactory. All was largely due to his labors as the chief executive officer of the Society. The increase of new remedies was mentioned as unduly large, and stated that the temptation to use them to the exclusion of reliable remedies was often carried so far as to result in detriment to the patient. He advised a committee of four to report on new remedies. The tendency to exalt specialists at the expense of the general practitioners was deprecated. He commended, in the highest terms, the results achieved by the State Board of Health, particularizing many special points. The vexed question of the code of ethics was gracefully touched upon, with the conclusion that soon it would be abolished, having outlived its usefulness, but that time was not yet.

On motion of Dr. Wile committees were elected to carry into effect the recommendations of the President, and they reported appropriate measures.

The committee on the

SOCIETY'S CHARTER

was, on motion of Professor Carmalt, selected by the Fellows from each county, who each proposed one member, this committee to report to a special meeting at the call of the President.

There was a lively discussion on the need of any charter and upon the relations of the society to the Medical Institution of Yale College by Professors M. C.

White, S. G. Hubbard, and Dr. C. W. Chamberlain and others.

The Committee on Unfinished Business reported a by-law assigning duties to county censors, which was adopted.

The Committee on Miscellaneous Business reported, in reference to voluntary papers, that it was the duty of the Committee on Publication to decide upon their publication or rejection, but it should be upon the merits of the papers solely.

The Treasurer reported an increase of \$40 in receipts from those of last year, a decrease expense of \$76, and a balance of \$638—an increase of \$200 over that of last year very nearly.

This increase was due largely to Dr. W. S. Holmes, of Waterbury, who had collected all the arrears in his county. There was about one hundred dollars due nearly all collectable, if not all.

OFFICERS ELECTED.

The Nominating Committee reported the following officers who were duly elected: *President*—Dr. E. B. Nye, of Middletown; *Vice-President*—Dr. B. N. Comings, of New Britain; *Treasurer*—Dr. E. P. Swasey, of New Britain; *Secretary*—Dr. S. B. St. John, Hartford; *Committee on Matters of Professional Interest*—Drs. W. C. Wile, J. H. Grannis, and E. C. Kinney; *Disseminator*—Dr. N. E. Worden; *Alternate*—W. H. Holmes.

When

THE DELEGATES TO THE NEW YORK MEDICAL SOCIETY was reached it was moved to

LAY THEIR NOMINATIONS ON THE TABLE,

which was carried, after a short discussion or rather brief statement of the reasons for such action, which was, in brief, viz., the attitude of the New York Medical Society toward the American Medical Association.

PROFESSOR S. G. HUBBARD presented the report of the Committee on the Revision of

THE LAW RELATING TO CORONERS.

He stated that there had been no definite plan agreed upon, but all the members had worked hard and efficiently, each in their own way, and the result was one the Society and State might well be proud of, as the need of such action was notorious.

DR. CHAMBERLAIN spoke of the work done by Drs. Porter and Cleaveland, both of which had, at their own expense, visited Boston several times to learn the details of the working of the Massachusetts law, and thus secured all the results of their experience. The law apparently was an improvement over that law in many respects, while like it in most essential respects.

DR. PORTER presented copies of the law to the Society, and spoke of its peculiar points of merit.

The Committee on Honorary Members reported the name of Dr. John I. Billings favorably, and he was elected unanimously.

Dr. J. E. Reeves, of Wheeling, West Va., and Professor T. A. Emmett, were proposed for honorary membership.

The following were elected members of the Committee on revision of the charter, etc.: Dr. C. W. Chamberlain, Professor W. H. Camall, Dr. F. N. Bramman, Dr. G. F. Lewis, Dr. H. W. Bull, Dr. E. A. Hill, Dr. G. W. Burke, Dr. A. R. Goodrich.

THE ARMY MEDICAL MUSEUM AND INDEX CATALOGUE OF SURGEON-GENERAL'S OFFICE

were endorsed emphatically in a series of resolutions, which the secretary was directed to send to every member of Congress from this State. The general idea of a medical register of New England, as proposed by the Massachusetts Medical Society, was endorsed in general, without entering into details.

Dr. W. C. Wile, Professor W. H. Camall, and Dr.

Charles Gardiner, the Committee on Increase of Fellows, and making ex-Presidents a Board of Counsellors, etc., reported that the by-laws should be so changed as to accomplish this. That the secretary should receive yearly fifty dollars, the treasurer twenty-five dollars, and that the number of Fellows should be increased by seventeen, so that fifty-five should be elected in place of thirty-eight, as now. They also advised that the secretary should be a permanent office. The report was accepted, and the proposed amendments referred to the next Convention for action.

It was voted that the annual tax should be two dollars, payable on and after June 1st; also that seven hundred copies of the proceedings should be published.

The Committee on Business reported favorably on the following, which were passed.

AMENDMENT TO BY-LAWS: THAT NO VOLUNTARY PAPER BE PUBLISHED THAT HAD NOT BEEN READ BEFORE SOME COUNTY SOCIETY.

By rule, this lays over a year.

Resolved, That the Legislature be memorialized by the Secretary to pass a law that

NO PROPRIETORY OR PATENT MEDICINE BE SOLD

in this State, unless there was plainly printed upon the label the formula, with a heavy penalty if the contents do not prove true to formula.

Resolved, That no resolution shall be received by the Secretary unless it be plainly and legibly written.

That all persons making remarks upon any subject should write them either before or after delivery, and that the Secretary be directed to procure, at expense of the Society, lap-tablets for this purpose.

The Auditing Committee reported the treasurer's report correct.

It was voted that each county society elect two fellows to serve on the Nominating Committee, the second as alternate; also that each such society elect alternates for every fellow.

The Society then adjourned.

Wednesday evening, the Hartford Medical Society gave a reception at the United States Hotel, which was largely attended, and proved a pleasant occasion.

Thursday was the general meeting for literary exercises, commencing at 9 A.M.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

The Fifth Annual Congress, held in New York, May 21, 22, and 23, 1883.

MONDAY, MAY 21ST—FIRST DAY—MORNING SESSION.

THE Association met in the Hall of the New York Academy of Medicine, and was called to order at 10 A.M. by the President, DR. GEORGE M. LEFFERTS, of New York.

The Secretary, DR. D. BRYSON DELAVAN, of New York, then called the roll.

The following Fellows were in attendance: M. J. Asch, New York; F. H. Bosworth, New York; S. H. Chapman, New Haven; J. Solis Cohen, Philadelphia; W. H. Daly, Pittsburg; T. A. De Blois, Boston; F. Donaldson, Baltimore; J. H. Douglas, New York; W. F. Duncan, New York; L. Elsberg, New York; T. R. French, Brooklyn; W. Gleitsman, New York; U. G. Hitchcock, New York; E. Holden, Newark; F. H. Hooper, Boston; E. F. Ingals, Chicago; F. L. Ives, New York; W. C. Jarvis, New York; S. Johnston, Baltimore; R. H. Kealhofer, St. Louis; F. I. Knight, Boston; S. W. Langmaid, Boston; R. P. Lincoln, New York; G. W. Major, Montreal; E. C. Morgan, Washington; D. N. Rankin, Alleghany; Beverley Robinson, New York; J. O. Roe, Rochester; C. Seiler, Philadel-

phia; A. H. Smith, New York; and Clinton Wagner, New York.

The ex-Presidents of the Association were invited to seats upon the platform.

The PRESIDENT then delivered

THE ADDRESS OF WELCOME,

in which he greeted his colleagues and fellow-workers with cordiality and extended to them the right hand of fellowship and a most hearty welcome.

With reference to an inaugural address, Dr. Lefferts departed from a custom sanctioned by long usage, and omitted it, believing that the time thus usually spent could be much more profitably consumed in scientific discussion. A few words of congratulation were then said concerning the marked prosperity of the Association, the fact that the constitutional limitation of membership had already been reached, urging emphatically that the limitation should not be extended, and suggesting that it was no more than fair that the few drones which were in the hive should give place to those who were willing to assume the work and responsibilities of active fellowship.

After thanking the Association for the honor conferred upon him by electing him to the high office, the President referred to the social influence of the organization, bade his fellow-workers God-speed, and then proceeded to the regular order of business, which was the reading of papers.

A motion, limiting the time to be occupied by each speaker participating in the discussions to five minutes, was adopted without dissent.

DR. GEORGE M. LEFFERTS then read a paper on

NEW FACTS IN LARYNGOLOGY.

He directed attention to the following class of cases, of which he had seen two: A gentleman, young, strong, free from any abnormality of the heart, lungs, or kidneys, is sitting at the dinner-table, and at a certain point in the conversation, suddenly has a slight attack of spasmodic cough, falls from his chair, is completely unconscious; almost immediately rises, and resumes the conversation at the point where it ceased. Is there any relation between this slight cough and so grave a result as complete unconsciousness and a fall? This is not the first attack. Several had occurred during the past eight years, and repeated partial attacks of unconsciousness, lasting for a few seconds, but then passing away entirely. There is an incomplete history of hereditary neurosis. There is no evidence of convulsive movements during the attacks. The face becomes suffused. Examination of the larynx reveals a normal appearance; the pharynx is granular, and the uvula is not elongated. A second instance of the same affection had been seen by Dr. Lefferts, and these were the only two cases with which he had come in contact during his entire practice. In the second case there was no history of neurosis. The patient's sister was decidedly neurotic.

These cases had been called laryngeal vertigo by Charcot. In looking up the literature of the subject, he had been able to find the records of only seven published instances. Of the etiology Dr. Lefferts asked special consideration. Charcot believes them to be due to irritation of the centripetal laryngeal nerve, and that they are somewhat analogous to the cases of vertigo of Menière's disease. On the other hand, Dr. L. C. Gray questions the accuracy of this position, and believes that the two affections alluded to by Charcot are unlike. This author also substitutes for the term laryngeal vertigo, the term laryngeal epilepsy, at the same time stating that the affection differs from the ordinary epilepsy in the important fact that it is readily amenable to treatment. Is the disease a form of epilepsy? To substantiate that Dr. Gray claims that it is necessary to prove that the affection does not occur except in instances in which there is present a decided neurotic condition. An analysis of the cases already published seems to show that

it does not, but the rule is not absolutely invariable. Dr. Lefferts thought that Charcot's views seem not to be proved. On the other hand, is Gray correct; is the disease a form of epilepsy?

DR. L. ELSBERG, of New York, did not agree with either Charcot or Gray concerning the nature of these cases, but regarded them as cases of spasm of all the adductor muscles of the larynx, and to this completeness was due the brief duration of each attack and the safety of the patient.

DR. F. I. KNIGHT, of Boston, suggested that the etiology might be some disturbance of the respiratory function, as it was well known, for instance, that prolonged and rapid inspiration sometimes results in unconsciousness, showing simply that it does not require a neurosis or a neurotic tendency to produce unconsciousness.

DR. G. W. MAJOR, of Montreal, believed that the disturbance in the larynx was possibly one of the auræ involved in epilepsy.

DR. E. F. INGALS, of Chicago, suggested that the brief unconsciousness was very similar to the pseudo-apoplexy of fatty degeneration of the heart, suggesting that perhaps the cases referred to by Dr. Lefferts were in some way associated with disturbance of the respiratory centres.

DR. S. JOHNSTON, of Baltimore, thought the point made by Dr. Knight was a good one, and that possibly the attacks of vertigo might be due to rapid respiration.

DR. LEFFERTS, in closing the discussion, said that he agreed more especially with the suggestion that the laryngeal spasm was probably a variety of aura of epilepsy.

DR. S. W. LANGMAID, of Boston, then read a paper entitled

A COMMON FORM OF VOCAL DISABILITY RESULTING FROM PATHOLOGICAL PROCESSES—THE PHENOMENA USED TO DEMONSTRATE THE FALSITY OF ONE SYSTEM OF VOICE-TRAINING.

The form of vocal disability referred to was that seen in actors and singers, where an inability suddenly developed itself to sing above a certain note in the scale, or there was a sudden break in the voice. The voice is good for all notes within the conversational register. An interesting feature in these cases is the fact that laryngoscopic examination enables us to say exactly at what point in the register the voice will fail, and therefore is of service in indicating to the singer that music may be arranged accordingly, and is also of service to actors in the fact that they may be warned with reference to the occurrence of the accident when their voices are raised to a certain pitch. Dr. Langmaid believed that the cause of the affection is in most cases a fatigue of the vocal organs produced by unusual efforts, with or without some catarrhal inflammation of the mucous membrane. Ordinarily, the best artists are the subjects of the affection because from them are demanded the best, and most prolonged efforts. The history of the case almost always revealed unusual vocal effort, or, perhaps, only ordinary use of the voice has been demanded during physical prostration. There is slight injection of one or both vocal cords, or there may be none at all; the position of the cords is that of relaxation; the glottis fissure is simply elliptical or open through the entire extent; in other words, the ordinary laryngoscopic appearances of vocal fatigue, such as have been described by Dr. Cohen in his work on "Diseases of the Throat." Besides, Dr. Langmaid had noticed in typical cases that there was nothing unusual in the appearance of the larynx until, as the patient is made to sing from below upward, a certain note is reached, and then a change in the position of the cords becomes well-marked, and instead of a progressive closure of the glottis, especially of the posterior position, a sudden relaxation takes place; the cords receding; the vibrations are slight. The point at which this occurs in soprano and tenor voices is the ninth in the scale, in the key of C; that is, Ra above

Do, or D above C. In contralto and bass voices it occurs in the seventh in the scale.

The treatment of this condition belongs in part to the laryngologist, but mostly to the teacher. Dr. Langmaid was not aware that this condition of relaxation had been spoken of as a result of a school of training. That the strength of the voice might be restored he had reason to know by experiments. In conclusion, he stated that the results, in as far as examination of the larynx was concerned, were those of disability of the vocal cords from straining of the voice, the same as when there is an intentional form of misuse of the voice in attempting to sing falsetto at a degree of the scale where the normal tone is called for.

DR. C. SEILER, of Philadelphia, assented in general to Dr. Langmaid's paper, but he did not quite agree with him as to the production of the paresis of the laryngeal muscles being entirely due to the misuse of the voice. He had found in a large number of cases a peculiar inability to produce certain tones of the voice, which came on gradually and not suddenly, and finally terminated in a break in the voice. In the majority of these cases he had found enlargement of the pharyngeal tonsil, narrowing of the resonance space in the naso-pharynx. In a case which he had under treatment, the voice had materially improved after removal of the hypertrophied pharyngeal tonsil, and the improvement had been much more marked, he believed, than it would have been had the case been one of simple paralysis.

DR. W. H. DALY, of Pittsburg, referred to two cases which had come under his notice, like those described by Dr. Langmaid. In one there was no active disease of the naso-pharynx, the larynx appeared normal, there was no evidence of malformation, and certainly there was no enlargement of the pharyngeal tonsil. He believed that the patient was suffering from fatigue of the laryngeal muscles, especially of the adductors, and advised cessation of work. In the second case he found slight local difficulty, the lodgment of a film of Pittsburg's favorite soot upon one of the vocal cords. After this was removed he found a slight injection of the mucous membrane. The soot was removed and the hyperemia reduced, but after all this had been accomplished there was some loss of power in the vocal muscles when they were called upon to sustain high notes. He believed that even in robust cases something more than local treatment was necessary, and was satisfied that ergot especially, nux vomica, and other active nerve-stimulants would be sufficient to raise the vital action and assist in restoring the power to the muscles.

DR. G. W. MAJOR, of Montreal, said that the last patient referred to by Dr. Daly was under his care in his city, and on examination he found a condition of the larynx very much like that described by Dr. Langmaid, which he attributed to strain in the use of the voice. He ordered rest, together with the internal use of strychnia.

DR. DALY remarked that he saw the patient immediately after she came from Montreal.

DR. LANGMAID, in closing the discussion, thought that in certain cases hypertrophy of the pharyngeal tonsil might possibly be an efficient cause in the production of this condition, but at the same time this fact did not militate against the theory which he had advanced. Anything which diminished the naso-pharyngeal space, of course, would be serious to one who had always had free space there. He had used galvanism and nux vomica with benefit, although he had not tried ergot, which he believed was a favorite remedy with Dr. Daly, but he should hereafter resort to it with pleasure. Dr. Langmaid also stated that Dr. Elsberg, since the reading of his paper, had directed his attention to the fact that Mandel had described this class of cases, and had directed attention to the same point alluded to by himself. Until Dr. Elsberg directed his attention to this fact, he was not aware that the special method of comparison which he had mentioned had ever been adopted.

The PRESIDENT then appointed as *Nominating Committee*—Drs. Knight, of Boston; Asch, of New York, and Daly, of Pittsburg.

Auditing Committee—Drs. Johnston, of Baltimore, and Morgan, of Washington.

Dr. U. G. Hitchcock, of New York, was then appointed teller, and the Society elected as Fellows Drs. C. W. Chamberlain, of Hartford, Conn., and John N. Mackenzie, of Baltimore.

The President also read an invitation extended from the Philadelphia Laryngological Society to the members of the American Laryngological Society to attend their regular meeting, to be held on Friday, May 25th. The invitation was accepted with thanks.

The Association then adjourned, to meet at 3 P.M.

FIRST DAY—AFTERNOON SESSION.

The Association was called to order at 3 P.M. by the President.

The first paper was read by DR. FRANK DONALDSON, of Baltimore, on

THE DESTRUCTION OF NASAL POLYPI BY CHROMIC ACID.

The author remarked that the points to be aimed at in the treatment of nasal polypi were their prompt and rapid removal with as little pain and small a loss of blood as possible, and in a manner to prevent their recurrence. He then referred to the three methods ordinarily resorted to for this purpose, and spoke of their advantages and also of their disadvantages. The forceps, the oldest method and most generally employed, is attended with great pain, considerable loss of blood, and often with ulceration of the adjacent structures. It is very effective if the pedicle is removed near its insertion. The sensibility of the mucous membrane can be somewhat diminished by the use of the spray of ice water containing salt, although the mucous membrane cannot be rendered so insensitive that the use of the forceps will be rendered painless. The advantages of this method are, comparatively short time occupied in the operation and the frequent non-recurrence of the growth. The author then made mention of cutting forceps, snares, and other mechanical apparatus for the removal of polypi, directing special attention to Jarvis' completed instrument. According to his experience, however, it is not an easy matter to get hold of the pedicle with any snare, and, according to his experience also, if the snare only is resorted to, the growth almost invariably returns. After speaking of the use of the galvano-cautery, he directed attention to the use of caustics, and stated that they had been abandoned very largely because they frequently injured the adjacent tissue. Glacial acetic acid injected into polypi destroys them, but when it touches the mucous membrane it inflames it and causes great pain, and destroys a part of it, although its irritant properties can be easily neutralized by spraying the part by aqueous solutions. The agent which he had employed most satisfactorily and most successfully was either minute crystals of chromic acid or a solution of one hundred grains to the ounce. It is a powerful escharotic, does not cause pain, its application is not followed by hemorrhage, and when properly used its action can be perfectly controlled. It is also an antiseptic and a disinfectant, more than all the acids or metallic salts which had been tried. Its action is prompt and not penetrating. His mode of application was, first, to moisten the mucous membrane with a lead lotion to protect it, and then taking the paste with a glass rod, very thin and pointed, stick it into the centre of the polypus as far as possible, and by turning the rod wipe off all the acid in the growth itself. The growth crumbles at once, and is removed without pain and without hemorrhage with the forceps. Sometimes irritation follows the local application, but the lead water, if effectually applied, protects the adjacent structures.

After the application of the acid, if it is desirable, the snare can be used with greater precision than before. It can be used in both varieties of gelatinous polypi. In the treatment of fibromata it is valuable, but not to the same degree as in the gelatinous polypus. He wished to be distinctly understood that he did not recommend it to the exclusion of surgical methods, but he had found it effective as an aid to them by destroying the substance of the neoplasm, in making the surgical operation less painful and less bloody, if it was subsequently to be employed, and it was also a very valuable adjuvant as a supplementary application for destroying the insertions of the growth and thus prevent their reformation.

DR. W. C. JARVIS, of New York, referred to a case of marked deviation of the septum, in which, after its removal, he discovered that the mucous membrane at the root of the nostril was covered with small polypi, which were gelatinous in appearance. These were removed with a very fine wire and subsequently the attached bases were touched with chromic acid. The point which he wished to make was that a return of polypi was to be accounted for not so much on the supposition that they returned from the roots of the stump which was left, as from the polypoid tissue which surrounded the pedicle, and that the application of the chromic acid after the surgical procedure was not so much for the purpose of killing the roots of the large polypi as in preventing the growth of the embryonic polypi, which would enlarge if permitted to remain.

DR. W. F. DUNCAN, of New York, thought that a permanent cure could be effected only by the removal of a portion of the turbinated bone from which the polypi spring; and, according to his experience and observation, unless this was done there had been a recurrence in as much as eighty per cent. of the cases, from one to five years after the growth had been removed by any other method.

DR. C. SEILER, of Philadelphia, spoke with regard to the pathology of nasal polypi. He had invariably found that the gelatinoid variety was a localized hypertrophy of the mucous membrane covering the turbinated bone, which has undergone myxomatous degeneration. According to his experience, the escharotics had given rise to more pain than had the use of the cold-wire snare, provided that the wire écraseur was tightened slowly. Further, he had found that if all the polypi are removed there will be no recurrence. He does not believe that a tumor grows from the stump, but that what appears afterward is a new formation, with localized hypertrophy the same as in the original growth, undergoing myxomatous degeneration. He had never experienced any difficulty in adjusting the snare about the base of a polypus. He preferred the use of the galvano-cautery to any chemical application.

DR. W. H. DALY, of Pittsburg, had used chromic acid, but not exclusively, and had devised a modification of the ordinary scoop, a curette without a fenestrum, made of different sizes, and upon the concave surface the copper was picked up so as to make little meshes sufficiently deep to hold fine crystals of chromic acid. He had found this a very convenient method of applying the remedy to small growths. According to his experience, however, it mattered very little as to what caustic was used, as he had obtained equally satisfactory results with acid nitrate of mercury, and glacial acetic acid.

DR. DONALDSON, in closing the discussion, remarked that he had used all other caustics which had been recommended, but he preferred the chromic acid. He did not wish to say that the pedicle could not be removed with the snare, but that the insertion of the growth could be removed better and more thoroughly with the snare, after chromic acid had been used.

DR. F. I. KNIGHT, of Boston, then read a paper on

CHOREA LARYNGIS,

in which he first directed attention to the close relation

existing between chorea and hysteria. The object of the paper was to call attention to the different kinds of cases which have been reported as chorea laryngis, and to invite discussion upon the same. Chorea laryngis was probably but one of the many manifestations of a general affection. There were three varieties which had been described. First, that in which not only the adductors of the larynx were involved, but the expiratory muscles of the chest are affected, characterized by cough occurring in paroxysms, accompanied with more or less vocal sound, the barking or crowing character of the cough sometimes occurring suddenly, sometimes at particular periods of the day, usually affecting patients between eight and fourteen years of age—these were the leading symptoms mentioned. On examination of the larynx in these cases only structural changes were discovered. The second class of cases were those in which the muscles of the larynx alone had been affected, particularly the thyrohyoid muscle. The author of the paper then reported one case of chorea of the adductors of the larynx without any affection of the expiratory muscles, and hence no effort at coughing. In this case there was a peculiar ticking in the head which the patient heard and which he could hear, and which he identified as a clicking together of the vocal cords. He believed that it was a unique case, at least was in his experience, and, so far as he had been able to find, in literature; that is, a case in which the spasm was rhythmical, and in which it continued during sleep. Third, and which did not, strictly speaking, belong under the head of chorea laryngis, those cases in which the expiratory muscles alone were affected.

DR. LANGMAID, of Boston, spoke of the extraordinary rhythmical movements of the vocal cords in Dr. Knight's case.

DR. E. C. MORGAN, of Washington, referred to a case occurring in a girl ten years of age, associated with chorea manifestations of the expiratory muscles. The rhythmical movements were entirely absent during the night in his case. The most interesting feature was the barking, crowing cough during the daytime, occurring nearly as often as every five or ten minutes. There was no disturbance of articulation. After exhausting nearly all remedies he had obtained the best results from the use of Fowler's solution and monobromide of camphor.

DR. E. F. INGALS, of Chicago, referred to a case in which there was a peculiar rhythmical movement of the levator palati muscle with a clicking sound with each contraction of the muscle. This certainly did not come from the larynx, and he had attributed the clicking noise to the movement of the muscle which opens the Eustachian tube in some way.

DR. LANGMAID then recited the history of a case in which the crowing, barking noise was the most distressing symptom, and after close observation it was found that it was preceded by opening the mouth. He first endeavored to produce a moral effect upon the patient, and then told her that the moment when her mouth opened to close it, which she readily carried out and it succeeded effectually in stopping the peculiar cough.

DR. E. FLETCHER INGALS, of Chicago, then read a paper on

THE TREATMENT OF LARYNGEAL PHTHISIS.

There are three prominent indications: First, to relieve pain; second, if possible to cure the disease; and, third, failing in either of these, to modify the course of the affection and prolong the patient's life. He believed that these indications could be met successfully in quite a proportion of cases. Pain can generally be relieved by topical applications, even though internal medication is of but little avail. The second indication is met best by the combined topical and internal medication. In the third place, we may succeed in modifying or relieving pain, and enable the patient to swallow, and so pro-

long life. Dr. Ingals then gave the history of a few cases which illustrated that the indications mentioned could be satisfactorily fulfilled. He recited the history of two cases which illustrated that laryngeal phthisis can be cured when the pulmonary complications are improving. One favorite local application which he had employed was a combination of carbolic acid, morphia, and tannic acid. He had used eucalyptol with benefit in several cases. In his hands iodoform had given but little or no relief from pain, and had failed to produce any perceptible curative effect. His conclusions were that we may meet the first indication better by topical applications than by any other means, and that we may confidently expect to give relief in a considerable proportion of cases. Second, that a limited proportion of cases may be cured by local and general treatment, the former sometimes being the most important factor. Third, that in many fatal cases life may be prolonged by local applications which relieve the patient from the exhaustion of the pain and irritating cough, and at the same time allow digestion of food.

DR. WILLIAM C. JARVIS, of New York, then read a paper entitled

THE HEALING OF ULCERS IN LARYNGEAL PHTHISIS.

He prefaced his remarks with a reference to the incredulity of the medical profession regarding the cure of phthisical ulcers in the larynx. This was partly due to the fragmentary histories of the cases reported, insufficient evidence, and claims for cure based upon peculiar methods of treatment. The history of one case was given in which the phthisical ulcers had entirely healed. The evidence of the physicians and specialist from whom the case had been transferred and the appearances described by the author of the paper demonstrated conclusively advanced laryngeal phthisis. The lungs had been examined by experts and co-existing pulmonary phthisis discovered. Treatment was explained in detail. It consisted locally in the frequent use of fine alkaline sprays. Atomized alkaline fluids were employed for cleansing. Local sedation was practised and iodoform freely used. Constitutional remedies were considered of importance, to quiet cough, favor cicatrization, promote sleep, relieve restlessness, and to nourish the enfeebled body. Climatic change was considered necessary. By carefully employing these mild means, a patient threatened with death from extreme pain in deglutition, was restored to health and comfort. One vocal cord had been almost entirely eaten away, firm cicatricial tissue forming the excavation. He showed there was analogy between certain forms of phthisical ulcers in the larynx and simple superficial sores in the mouth; that these buccal ulcers were sometimes produced by the irritant action of perverted secretions upon slight wounds. In these cases a pellicle of shellac varnish or simple eschar was sufficient to protect and heal the ulcer. If the lesion occurred on a part in frequent motion it was converted into a painful ulcer, producing discomfort in deglutition and a train of symptoms resembling those found in certain cases of laryngeal phthisis. He believed the incipient wound might be caused by violence, like a cough, injuring the friable and thickened laryngeal tissue.

Constant motion and acrid pulmonary discharges completed the analogy. He considered certain forms of phthisical ulcer, easily recognized by certain peculiarities described by him, curable. Far advanced ulcer, involving extensively the hard structures of the larynx, invariably proved fatal.

A new laryngeal powder-blower, invented for treating ulcerations of the larynx, was exhibited.

DR. S. JOHNSTON, of Baltimore, referred to one case which he had observed *from the beginning*. His diagnosis was sustained by Morell Mackenzie during his late visit to this country. The first appearance was that of white puncta, which resulted in ulcers that coalesced; physical examination of the chest negative; the epiglottis

presented the usual cocked-hat appearance seen in laryngeal phthisis. The ulcers entirely healed under internal treatment with inhalations twice daily, from a steam atomizer, of a solution of sulphate of zinc, one grain, and carbolic acid, two grains, and at the end of a month there was a well-marked cicatrix.

DR. F. DONALDSON, of Baltimore, said that great relief could be afforded not only by sprays, antiseptic inhalations, and local applications of iodoform, but he regarded it as important to sustain the nutrition of the patient by the use of the stomach-tube when there is difficulty of swallowing. He had repeatedly seen apparently phthisical ulcers at least heal under treatment by the local measures just mentioned.

DR. F. H. BOSWORTH, of New York, spoke of the confusion still existing concerning diagnosis of laryngeal phthisis or tubercular ulcers. He thought that no ulcers should be regarded as tubercular except those which were attended by a peculiar boggy inflammatory swelling, most frequently upon the arytenoid cartilages, ventricular bands next, rarely upon the vocal cords, and in a still less proportion of cases upon the epiglottis; the ulcer is covered with bright yellow spots, and never secretes anything except ropy mucus. He had certainly cured cases of laryngeal phthisis, and by the mild plan of treatment which he recommended several years ago, and described by Dr. Jarvis—cleansing, application of morphia, and also the local use of iodoform, done every day until the patient is absolutely comfortable.

DR. J. SOLIS COHEN, of Philadelphia, thought that recovery took place in some cases, but that it could not be said beforehand which they were. "They get well in spite of us." He regarded the absence of pus as one of the most important diagnostic features of phthisical ulcers of the larynx. Tubercular ulcers in the lungs healed, why not in the larynx? He saw no reason why they might not.

DR. F. I. KNIGHT, of Boston, referred to cases in which the local symptoms disappeared, although there was a steady failure in the general condition of the patients. They healed by the constant application of cold carbolic acid spray—two grains to the ounce of water—with frequent applications of morphia and sugar. He thought it was the constant cleansing process that was, after all, the essential factor in the treatment. Although it was well recognized that tubercular disease of the larynx was frequently arrested, as is also seen when the lungs are invaded, we are unable to say in which cases such a result is to occur, and not much encouragement could be held out to the patient, even if it was arrested. He wished to have the question of the influence of climate on these local conditions discussed.

DR. M. J. ASCH, of New York, said that in all the cases of laryngeal phthisis in which he had seen good results follow treatment there had appeared evidence, before the patients were dismissed, that the ulcerations were syphilitic in character, although pulmonary disease also existed.

DR. R. P. LINCOLN, of New York, believed that iodoform in the treatment of ulcers of the larynx associated with phthisical manifestations in the lungs was chiefly beneficial not in the early stages of the inflammation, when there was an unbroken surface, but later. Keeping that idea in mind, perhaps the discrepancy concerning the effect produced by the drug might be removed. He also believed that the beneficial influence of sprays, etc., was increased by the addition of a few drops of the essence of peppermint to the solution, an agent especially cooling to mucous membranes.

DR. G. W. MAJOR, of Montreal, thought that the best local application was atmospheric, although under the general plan of cleansing, etc., relief and, for the time at least, an arrest of the process might be secured.

DR. W. F. DUNCAN, of New York, spoke of the value of the mild plan of treatment mentioned by Dr. Bosworth, and said that in the last sixteen or seventeen cases which

were under the observation of Dr. Bosworth and himself, all terminating fatally, the laryngeal symptoms disappeared entirely, and so far the patients were comfortable.

DR. KNIGHT said that according to his experience, while patients in the incipient stage of pulmonary phthisis were benefited by living in a rarefied atmosphere, those suffering from laryngeal complications were made worse by such a change.

DR. INGALS said that in one of his cases there was none of the boggy tumefaction referred to by Dr. Bosworth. Yet it seemed to him to be reasonable to conclude that when a patient has well-developed pulmonary phthisis and laryngeal symptoms develop, they are also due to the same cause, and that the ulcers in those cases are tubercular. For his own part he had not found the boggy swelling present uniformly. He regarded time as the most important element in the treatment. As suggested by Dr. Cohen, some of these patients, so far as the larynx is concerned, will get well if they have an opportunity. As to whether any of his cases were syphilitic or not, he thought the pulmonary signs justified his diagnosis. With regard to climate, he did not send his patient to Colorado on account of his laryngeal affection, but for the pulmonary trouble, and believed that a dry atmosphere was unfavorable for laryngeal ulcers.

DR. JARVIS thought that no difficulty should be experienced in differentiating between syphilitic and phthisical ulcers. He was unable to see how mere inhalations could produce any curative effect upon these ulcers.

DR. F. H. BOSWORTH, of New York, then read a paper entitled

PARESIS OF THE CONSTRUCTOR MUSCLES OF THE PHARYNX
SIMULATING SPASMODIC STRICTURE OF THE OESOPHAGUS,
WITH REPORT OF CASES.

The histories of five cases were given, which illustrated the myopathic affection, what we had been taught to regard as myopathic paralysis, neurotic in character. Dr. Bosworth believed that the affection was essentially muscular and could be best explained by the general law that muscles which are overworked show a tendency to break down, and this tendency is especially marked if they are situated just beneath a diseased mucous membrane. The author of the paper then spoke of the inherent tendency in certain muscles of the larynx to become the seat of myopathic paresis. His cases were treated with rest, strychnia, salt-water bathing, etc., and all the patients except one recovered.

DR. COHEN, of Philadelphia, regarded this class of cases as essentially hysterical, certainly the majority of them as they had occurred in his practice. He had obtained the greatest success by placing a nurse over the patient and insisting that food should be swallowed.

DR. LANGMAID, of Boston, had had the best success in their treatment by passing bougies, beginning with a very small one and advancing gradually to one of large size.

DR. KNIGHT of Boston, had had similar cases, but there was no loss of electro-muscular contractility. He had felt that in most cases the difficulty was due to hyperæsthesia and was best overcome very much in the way mentioned by Dr. Langmaid.

DR. BOSWORTH said the question of hysteria was excluded in his cases because there was unquestionable sluggishness of the muscles and anæsthesia when touched with the probe.

The Association then adjourned to meet at 11 A.M. on Tuesday, May 22d.

TUESDAY, MAY 22D—SECOND DAY—MORNING SESSION.

The Association was called to order at 11 A.M. by the President.

DR. THOMAS R. FRENCH, of Brooklyn, read a paper
ON PHOTOGRAPHING THE LARYNX.

The paper was illustrated with photographs and ap-

paratus. The conclusions arrived at were the following: 1, That better photographs have been taken with stationary apparatus than last year; 2, a camera has been so adapted that it can be held in the hand and be quickly placed in position; 3, photographs are taken instantaneously by a trap shutter; 4, parts reflected in the larynx are alone exposed; 5, photographs can be taken without the patient's being aware of the object of the procedure; 6, photographs of diseased conditions can be taken (first time on record); 7, photographs of the posterior nares have been taken (first time). Several of the Fellows spoke in commendation of the work of Dr. French.

A paper on

CONGENITAL TUMORS OF THE LARYNX,

by DR. H. A. JOHNSON, of Chicago, was read by Dr. Mackenzie, of Baltimore. The paper contained the report of five cases.

DR. KNIGHT, of Boston, stated his conviction that, from the natural history of papilloma in children and from the sequences of the operation, the best mode of procedure in such cases is to avoid thyrotomy; simply perform tracheotomy and let the growth alone until the child is old enough to allow operation through the mouth, at all events, is given opportunity for spontaneous expulsion of the neoplasm. Thyrotomy is pretty sure to injure the voice permanently. There is also a great chance for the growth to return, and unless urgent indications existed he would avoid this operation.

DR. COHEN, of Philadelphia, doubted whether congenital papilloma of the larynx occurred so frequently as some had imagined. His own opinion was that the occurrence of these growths, congenitally, in the larynx, was exceedingly rare. Papillomatous tumors are very apt to develop in the larynx after the occurrence of measles, diphtheria, whooping-cough, etc., and even after ordinary catarrhal inflammation, all of which are diseases of childhood, and may appear very early in life.

With regard to treatment, any operation in the cervical region, whether it opened the air-passages or not, is liable to be followed by pneumonia. Perhaps the reduction of the temperature of the pneumogastric nerve from exposure might have something to do with the result; therefore it might be possible that better results would be obtained by operating in a warm room and taking precaution to maintain the temperature of the parts at as near the normal as possible. He was opposed to the ordinary operation of thyrotomy unless there was urgent necessity for it. The impairment of the voice, however, he regarded as a secondary consideration, if life could be saved by the operation. The chief danger, in his opinion, was that if a large quantity of cicatricial tissue existed, it would interfere with the enlargement and proper changes in the larynx, which occur normally at about the time of puberty, and in that way permanently impair the patient.

DR. MAJOR, of Montreal, reported two cases. In one the child still wears the tracheotomy tube and is doing very well. The operation was performed in 1880. The other patient died without the benefit of any operation. He believed that thyrotomy, even at the peril of injuring the voice permanently, was preferable to opening the cricothyroid membrane.

DR. DUNCAN, of New York, gave the history of two cases; in one the child died of suffocation; in the other Dr. Fred. Lange performed tracheotomy, subsequently thyrotomy, and the child recovered entirely, although with a somewhat impaired voice.

A paper on

LARYNGEAL PARALYSIS FROM ANEURISM,

by DR. WILLIAM PORTER, of St. Louis, was read by title. The Association then adjourned to meet at 3 P.M.

(To be continued.)

NEW YORK ACADEMY OF MEDICINE.

SECTION IN OBSTETRICS.

Stated Meeting, April 26, 1883.

ALEXANDER S. HUNTER, M.D., CHAIRMAN.

DR. R. TAUSZKY read a paper entitled

HOW TO SECURE THE BEST POSSIBLE PHYSICAL CONDITION
AFTER PARTURITION.

The author of the paper began with the question, Why is it that almost every woman as soon as she becomes a mother begins to suffer from some form of pelvic disease? In support of the words "almost every woman," he referred to the very large percentage of gynecological cases in which the morbid condition present could be traced directly to childbirth, and then asked the significant question, By what means can the occurrence of these conditions be prevented? To the influence of the old term "meddlesome midwifery" he believed that a part of the explanation could be traced, but he regarded meddlesome midwifery scientifically applied as one of the most effectual means of preventing the conditions under consideration. Hygienic and antiseptic midwifery under intelligent direction, even though it be subjected to the term "meddlesome," should be practised in every case of normal labor. Although at the present time it is so practised by most surgeons it is not, unfortunately, carried out to an equal extent by obstetricians. How is this method to be carried out in cases of normal labor? First of all, the accoucheur should be careful to cleanse his hands with soap and water, remove all foreign particles from beneath the nails, and then wash the hands in either a three per cent. solution of carbolic acid, or, what is probably more available, pure vinegar, and afterward oil the hands with carbolized oil of the same strength of carbolic acid mentioned. All instruments and articles used about the woman should be cleansed and disinfected by similar means. Just prior to confinement, or early in the first stage of labor, the bowels should be freely moved by an enema, repeated if necessary. The bladder should be emptied, and if catheterization is necessary the urine should be drawn with a soft Nélaton catheter which has been thoroughly cleansed in boiling water and afterward disinfected. The vulva should be bathed with some antiseptic solution, such as a very weak solution of carbolic acid, perhaps with the addition of a small quantity of glycerine, or with a solution of thymol.

The author recommended careful dilatation of the cervix with the fingers. He also spoke of the advantage which might accrue from gently pushing up the anterior lip of the cervix above the symphysis. Tough membranes also may be ruptured with great advantage. He recommended the use of chloroform, especially in primiparæ, not carrying the anæsthetic, however, to the production of full unconsciousness. The forceps in very many cases, if judiciously used, were advantageous rather than disadvantageous, and should be used rather than allow the head or shoulders to press unduly, for any considerable length of time, upon the perineum.

The cord should not be tied until the umbilical vessels cease to beat. Dr. Tauszky regarded this as a point of practical importance. He also recommended Crede's method of expression of the placenta. The genital passages should be carefully examined after removal of the placenta, and all slight lacerations or wounds should be closed, and the same rules adopted as in the treatment of wounds of soft parts elsewhere, and they should be carefully covered with some antiseptic dressing, such as the application of iodoform, etc. He recommended the use of the abdominal binder. He claimed that the child should be applied to the breast at the earliest moment, believing that the material which it derived in this way from the mother was more beneficial to it than any article which could be administered; and at the same time it

was beneficial to the mother in exciting or maintaining uterine contraction. In multiparæ he recommended the administration of a drachm of ergot after the delivery of the placenta. He believed that ergot in a normal labor should never be given before the expulsion of the child. According to his experience after-pains, when the case was managed according to the plan outlined above, scarcely ever occurred. Should they occur of course they should be controlled by the use of anodynes.

In the management of the puerperal condition careful disinfection should be strictly observed. The thermometer should be used twice daily in the axilla. The breasts and the nipples should receive careful attention. He recommended the following as an application for excoriated nipples.

R. Balsam Peru..... grm. iv.
Olei amygdal..... grm. vj.
Aque rosæ..... grm. xxxv.
Mucil. acac..... grm. vj.

Mix, and apply after each nursing, the nipples being carefully cleansed.

Dr. Tauszky laid special stress upon the occurrence of hemorrhage after parturition, and remarked that a little hemorrhage after parturition is very dangerous, and should be arrested. He took the strong position that the accoucheur should be regarded as guilty of malpractice who would permit a slight quantity of blood to escape from the genital organs of a woman for days after parturition. He maintained that not a single drop of blood should appear after the completion of the third stage of labor; that the napkins when removed should be perfectly free from color; that should they be colored the physician should at once institute an examination with reference to the source from whence the blood came, and set about arresting it.

The bowels need not be moved until the third day after labor. It is not necessary, is often dangerous, is even fatal sometimes to use intra-uterine carbolized injections once or twice daily up to the second day, even after natural labor. He believed that such injections should be used only when the lochia are offensive, and febrile movement has developed. When the lochia are offensive and there is some fever present he invariably syringes the vagina several times a day with a disinfectant solution, but intra-uterine injections post-partum are necessary only in cases of internal violence, such as sometimes attends the manual separation of the placenta or the use of the forceps. When such injections are used, he preferred thymol or simple water to carbolized water, which could be introduced either through a soft catheter or the exceedingly convenient tube invented by Dr. Chamberlain. The injections might be repeated until the fetor of the lochia was either markedly diminished or entirely corrected.

Dr. Tauszky protested against the teachings of Dr. Goodell, of Philadelphia, with reference to the parturient woman being permitted to assume the upright position within three days after labor. He believed that the doctrine was a dangerous one, and unwarranted, and maintained that the recumbent posture should be kept, changing occasionally from side to side, for at least eight days after normal delivery, and especially until the uterus has returned to the pelvic cavity. Dr. Tauszky then referred to his experience on the frontier while in the army, and stated that it was not only among the civilized, but also among the savages, that women suffer from diseases peculiar to their sex, and stated that gynecological affections among the squaws were not at all uncommon. He attributed a large percentage of these conditions to early rising after parturition. He then detailed the history of a case which terminated fatally, and, as he believed, chiefly because of the early getting up of the patient.

For pelvic peritonitis, in case it developed, he regarded cold applications as the best that could be employed, but more especially in the early inflammatory stages. Both

the pain and the hyperæmia were lessened by the use of cold. At first the applications must be repeated very frequently.

Dr. Tauszky then exhibited some of Lieter's (of Vienna) devices for reducing intra-pelvic temperature, which consisted of metallic cylinders three-fourths of an inch to an inch and a quarter in diameter, and two inches in length, within which were coils that terminated in two extremities which projected from the extremity of the metallic bulb, and to which india-rubber tubes could be attached that conducted the water from a fountain above through the bulb into a basin below. He also exhibited a small device of the same kind which could be used for the application of cold to the cervical or intra-uterine canal.

After fever has disappeared warm baths or sitz baths could be resorted to, but he believed that the use of warm injections for peritonitis were dangerous.

Discussion on Dr. Tauszky's paper was opened by Dr. W. M. CHAMBERLAIN, who said he agreed entirely with the author of the paper in the idea of observing scrupulous cleanliness in the management of cases of labor, and believed there was truth and force in the idea. One statement made by Dr. Tauszky, however, struck him as a remarkable one, and one to which he could not subscribe; that is, that the attendant should not be content with himself or his patient, and should not leave her so long as there was any hemorrhagic flow from the vagina. Certainly that conflicted with his own experience and his ideas upon the subject. He expected always a hemorrhage, slight, it is true, but an intermittent flow of blood for from twenty-four to thirty-six hours after labor, and had not been concerned if it passed beyond that measure. He had never recognized, when proper cleansing of the vagina had been employed, that this slight amount of hemorrhage had been productive of any harm. He thought it was natural, almost necessary, and should not be interfered with except to prevent it from becoming excessive.

With regard to the dangers of septicæmia, he had read, as probably most had, the paper of Dr. Thomas, detailing some striking cases of septicæmia in which remarkable results had been obtained from washing out the puerperal uterus. Other writers also had related somewhat similar cases. The idea involved in Dr. Thomas' paper seemed to be that puerperal septicæmia means retention of morbid matter or the formation of morbid matter within the cavity of the uterus, and that that is the essential cause of puerperal septicæmia. Doubtless it is a very frequent, probably the most frequent cause, and in such cases the indication is to wash out the uterus if the cavity can be easily reached. But Dr. Chamberlain believed there were other causes which should be also recognized, for example, breach of the surface anywhere within the entire length of the genital canal, occurring in labor, may allow the entrance of septic matters into the lymph and blood; also any surgical operation in the non-parturient patient may become like occasion of septicæmia and peritonitis. He had certainly seen many cases of puerperal septicæmia which could properly be correctly assigned to lacerations of the perineum and vulva. If there were in addition retention of the secundines and development of morbid products in the cavity of the uterus, all the conditions of septic infection would be present.

As to intra-uterine injections, he would show a specimen tube, employed by himself and many others, and known as Chamberlain's tube. It should be, and generally had been, made of soft or unannealed glass, which was not easily broken. It is eighteen inches long, seven-eighths of an inch in diameter, rounded and closed at the entering end, and perforated on all sides by counter-sunk holes. To the other end a syphon-tube of india-rubber connected with a two-quart wash-bottle is attached. A one per cent. solution of pure carbolic acid (Schering's is the best) was employed. The tube should be passed without the aid of the guiding finger, and, he

believed, greatly simplified irrigation of both uterus and vagina. Care should be taken to leave no fluid remaining in the cavity of the pelvis.

Intra-uterine injections practised upon every lying-in woman would probably be mischievous, and is an unwarranted interference, which nothing except a septic condition of the uterus would justify. The indications that a septic condition is present are the fetid condition of the lochia. The existence of septicæmia is not an indication for washing out the uterus, unless the cause can be located within the uterus. It may be an indication for washing out the vagina, but not the uterus. He had never attempted to introduce his tube and wash out the uterus after the organ had undergone advanced involution. He thought the case which Dr. Johnson cited at a recent meeting of the New York Academy of Medicine was one in which the uterus had ceased to be septic and the occasion for the use of the instrument had passed away.

With regard to intra-vaginal irrigation for anti-febrile purposes, and the use of the cold coil to the abdomen, he had nothing special to say. He had already presented the subject to the Academy of Medicine about a year ago, and to the Medical Journal Association about eight years ago. It is probably not so strikingly efficient as is Kibbee's cot, but its use is so simple and so efficient that it can be adopted with very great and positive advantage in all cases where Kibbee's cot could not be made available. The idea of intra-vaginal cooling also occurred to him at the same time, but he had not practised it. He believed, however, that it was legitimate, and possibly a very valuable extension of the same idea. With his preference for india-rubber over metallic substances he should have continued to use rubber coil inasmuch as it may be difficult at times to secure the metallic tube, and the same idea could be accomplished with rubber tubing in an equally satisfactory manner.

Dr. JEWETT, of Brooklyn, said he endorsed the idea already advanced by the author of the paper, and sustained by Dr. Chamberlain, that the first and most important element in the care of puerperal cases was cleanliness. To promote this end it had been his practice to use the carbolyzed vaginal douche immediately after labor, using a two and a half per cent. solution immediately after the completion of the third stage of labor. From this practice he had seen no evil results. He also ordered the use of the vaginal douche every three or four hours for the first two or three days after confinement. With regard to intra-uterine injections, if had not been his practice to use them except where the vaginal douche has been tried and failed. He used the vaginal douche first, and if it did not immediately bring down the temperature, if evidence of septic infection were present, the intra-uterine douche was then in order. Dr. Jewett was inclined to the opinion that in the majority of cases puerperal septicæmia originates in wounds of the vagina and cervix. He thought, therefore, that the vaginal douche was usually sufficient. The objection to the frequent use of the intra-uterine douche was the liability to produce some traumatism, or to open some new avenue for absorption. The results, however, obtained from well-observed clinical cases must ultimately decide concerning its use.

With regard to the matter of rest after delivery, it had been his practice to keep the patient quiet in bed from twelve to fourteen days, and although the woman might be then allowed to assume the upright position, he always counselled that she should remain quiet during the third week. He was inclined to agree with the writer of the paper concerning Dr. Goodell's views, and thought that if Dr. Goodell examined his patients a year after labor he would find more or less evidence of the evils of the practice. Dr. Jewett believed it was important to secure the early and complete contraction of the uterus as soon as possible after the delivery of the child. In his practice, therefore, the third stage of labor rarely ex-

ceeded five to seven minutes, while most obstetric authorities advised that fifteen to twenty minutes, perhaps more, be allowed to elapse before the delivery of the placenta and completion of the third stage of labor. He believed it to be important that the third stage of labor be completed as promptly and as thoroughly as possible by stimulating at once the natural powers of the uterus. He would not approve of any method which favored the formation of deep thrombi in the structure of the uterus. He favored expression of the placenta, believing that the essence of the manipulation was compression during contraction; that is, the process was merely supplementing the natural powers instead of replacing them.

DR. BURRALL believed it to be a general principle that the more perfect the woman's health is, who is about to bear a child, the greater the probabilities were that she would accomplish her task with the greatest safety, and therefore it seemed that the care of the puerperal woman and the prevention of puerperal accidents should begin during pregnancy. Treatment of the puerperal woman preparatory to labor should begin several weeks before the expected confinement, and should be of such a character as to place the system in the best general condition possible. He thought the internal use of antiseptics before labor, perhaps for four, five, or six days, was reasonable. The functions of all the organs should be carefully examined, and such means taken as might be indicated to put them into the best possible condition. He also believed that the statement with regard to the proper use of the forceps during labor made by the author was very judicious. External pressure and the use of ergot immediately after labor he believed to be proper to avert hemorrhage. It had not been his practice to shorten the third stage of labor so much as had been mentioned by Dr. Jewett. He thought that sometimes more satisfactory results could be obtained by some delay than by the immediate completion of the third stage. He agreed with Dr. Chamberlain concerning the occurrence of a small amount of hemorrhage after delivery, and in that respect differed with the author of the paper. He thought that a little more than the usual quantity of sanguinolent discharge after labor was not specially disadvantageous, but rather otherwise. The use of antiseptic injections and douches he believed to be indicated after delivery of the placenta. With regard to the application of ice to the abdomen and intra-uterine injections, the necessity for their use usually arose at about the same time during the puerperal state; that is, upon the rise of temperature, which is usually accompanied with a fetid lochial discharge. Under these circumstances nothing produced more satisfactory results sometimes than the use of intra-uterine injections.

DR. JEWETT referred to another point which he had omitted to mention, that is, the examination of the patient at the end of the third or fourth week after delivery before she is discharged, with reference to possible lacerations of the soft parts or of the cervix, which occurred during labor and had been overlooked.

DR. BURRALL emphasized the point just made by Dr. Jewett. He also favored the use of the binder for two or three weeks after confinement. He also said that he could not endorse the views advocated by Dr. Goodell concerning the upright position, more especially for those whose pelvic organs are weak and need support.

DR. BROWN remarked concerning vaginal injections immediately after delivery, that it did not seem to him they were necessary in all cases. It seemed to him that neither the vagina nor the uterus was necessarily in an unhealthy condition at this time, and that nature provides for some of these conditions by the escape of more or less blood from the genital passages. He did not believe that such discharges necessarily implied an unclean condition, and therefore that their arrest was essential. He disliked to disturb the patient for such a purpose; further, he did not believe it was necessary to remain by the bedside of the patient until the

hemorrhage had entirely ceased. Dr. Brown then spoke of difficult labor possibly due to cicatricial formations succeeding manual removal of an adherent placenta and injury to the uterine walls.

With regard to antiseptics before labor, it did not occur to him that they should be administered, or that either pregnancy or labor should be looked upon as necessarily a sickness. He therefore did not see the utility of beginning a course of disinfectant treatment before labor commences.

DR. CARPENTER asked Dr. Tauszky if he wished to be understood as saying that not a single drop of blood should be seen in the discharges after the completion of the third stage of labor.

DR. TAUSZKY replied that no bleeding whatever should take place after labor; that not one single drop of blood should be seen.

DR. JACOBUS asked Dr. Tauszky how long he was accustomed to remain with the woman after labor.

DR. TAUSZKY replied that sometimes not more than ten or fifteen minutes; sometimes longer. When the uterus was once firmly contracted it had, according to his experience, remained in that condition and hemorrhage did not occur.

DR. JACOBUS remarked that Dr. Tauszky's experience differed entirely from his own, and that according to his observation a certain amount of hemorrhage had invariably taken place after the completion of the third stage of labor; sufficient, at least, to give the napkins a greater or less blood-stained appearance; further, he believed that this occurred in all cases.

DR. BURRALL then exhibited specimens of the

KOLA NUT.

The nut was introduced to the attention of the profession in England some eight years ago, and had been said to contain a combination of several properties, as the active principle of cocoa, coffee, and coca. It had been said to contain two per cent of caffeine. It had also had a good reputation as an agent for overcoming the appetite for alcoholic drink, and its reputation as an article for procrastinating desire for food was well known.

The Section then adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 25, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

(Continued from p. 558.)

CHRONIC DIFFUSE NEPHRITIS—CIRRHOTIC AND FATTY LIVER—FATTY DEGENERATION OF HEART, WITH HYPERTROPHY AND DILATATION—CEDEMA OF LUNGS—CALCAREOUS ARTERIES OF BRAIN—CEREBRAL SOFTENING.

DR. J. LEWIS SMITH presented specimens, with the following history: The patient was a woman, forty-five years of age, who was admitted into Charity Hospital, in nearly a moribund state, on April 16th, under the care of Dr. Walter L. Carr, House Physician, who furnished the following records: She was cyanotic at the time of admission, and her pupils, which were unequally contracted, did not respond to light. The skin was dry and harsh; limbs cool and somewhat cedematous; pulse, 90, not strong; respiration, 44; vaginal temperature, 96° F. She seemed to comprehend questions, but answered in a very slow and hesitating manner; said she had no headache, had vomited some on the previous day, and that her bowels were constipated.

The respiratory movements were increased; no vocal fremitus could be detected; percussion resonance over anterior part of chest good, except at left apex; posteriorly resonance rather dull, especially low down. Upon left side of chest respiration blowing in character in the entire lung, and expiration prolonged, but not

distinctly bronchial. Breathing on the right side similar to that on the left, but not so loud; no râles heard in any part of the chest. The heart-sounds were normal but weak. The urine, removed by the catheter, had a specific gravity of 1.020, was dark-colored, slightly cloudy, and contained ten per cent. of albumen. In it was a large number of small hyaline casts and a few large ones, with some granular matter.

The patient complained of pain on the right side of the abdomen, a little below the ribs. On palpation the abdomen was found resistant and hard, and the percussion dulness extended downward from the normal liver space to a line just above the umbilicus. The dulness extended to the left over the transverse colon. No indentation could be made. Abdomen not tympanitic, nor distended. Deep percussion sound over the lower part of the tumor resonant. 7 P.M.—Vaginal temperature, 97° F.; respiration, 24; pulse, 86. 10 P.M.—Pulse, 88; temperature, 97° F.; respiration, 24. She was restless, moaned often, and finally became more and more somnolent till her death, about eighteen hours after admission.

She was treated by purgative doses of elaterium, by digitalis, hot-air baths, alcoholic stimulants, etc.

At the autopsy a small amount of straw-colored fluid was found in the pleural cavities; no adhesions; lungs congested and oedematous; heart dilated and hypertrophied, dilatation predominating; walls of the heart more yellow than normal, and under the endocardium on the right side are irregular yellowish spots; trabeculae flattened, and the spaces between them enlarged; free border of mitral valve thickened; walls of left ventricle one-half inch thick; tricuspid orifice largely dilated. Kidneys: Diminished in size; capsules tear the surface on stripping; surface finely granular, and of a more yellow color than normal; section shows a general atrophy; in pyramids, radiating whitish striae; columns of the tubules more narrow than normal, and wavy appearance exaggerated; intertubular spaces enlarged, and of a reddish color, contrasting with the yellow color of the tubules; Malpighian bodies not recognizable.

Liver: Weight, 3 $\frac{1}{8}$ lbs.; increased in breadth, and diminished in thickness; old local thickening of capsule; surface slightly lobulated and firm; lobules small and irregular. This organ is cirrhotic and fatty. Spleen: Slightly enlarged and firm. Stomach and intestines: Apparently normal. Brain: Meninges cloudy; a large right vertebral artery, and very small left vertebral, so that the basilar is formed apparently almost entirely from the right vertebral; arteries at base of brain, both the large and small, are atheromatous. On the left side a large softened spot appeared in the upper anterior portion of the optic thalamus. Another similar softening a little lower than this, slightly involving the middle third of the internal white capsule. Two or three similar spots were found in the white portion of the hemisphere, and one in the pons Varolii on the left side. These spots were yellow.

Remarks.—"The liver, in regard to the state of which some doubt has been expressed, has been examined microscopically by Professor Welch, with the following results: 'It is fatty and moderately cirrhotic. There is a new growth of connective tissue, which, although only moderate in amount is unmistakable. There are patches of atrophied liver-cells. I think that the evidences of cirrhosis are to be made out with the naked eye, there being already a granular appearance on the surface, and a distinct lobulation on the cut section.'

"This woman, though in middle life, had disease of a fatal nature in nearly every important organ. There was a group of structural changes, such as we would expect to find only in advanced age. No doubt a life of debauchery, privation, and hardship renders men and women of the class to which this woman belonged prematurely old.

"The brain-softening was interesting, as it occurred on

the side in which the vertebral artery was abnormally small, and it seemed probable that the diminished blood-supply sustained a causative relation to it. What appeared before death to be an abdominal tumor was the right lobe of the liver, which lay unusually low and was prominent.

"The most conspicuous symptoms, and also death, appeared to be due more to the Bright's disease than to any other of the many lesions. Dr. Smith called attention to the subnormal temperature, which was constantly three or four degrees below that of health, during the time that she was under observation."

DR. JOHN F. RIDLON presented a specimen with the following history:

CHRONIC OSTEITIS OF THE SHOULDER-JOINT.

George G— was admitted to St. Luke's Hospital, April 3, 1883; twenty-three years old; single; a polisher, and a native of the United States. Service of Dr. Chas. McBurney.

He was indebted to Dr. Hunter, House Surgeon, for the history. Previous history good; parents healthy; no one in family has had phthisis, carcinoma, or syphilis. Patient has had gonorrhœa twice—last attack two years ago; never had a chancre; never injured or strained his arm in any way. About a year ago he first noticed stiffness and weakness at the left shoulder-joint, followed by pain on motion, but no pain while at rest. Next came noticeable atrophy of the muscles of the shoulder and arm. Three months ago an abscess appeared at the inner and front part of the arm, at the border of axilla, and pain became severe. Two months ago this abscess was opened, and has been discharging copiously since. He has lost in strength and weight; has cough and night-sweats; appetite poor.

Examination showed some cedema of entire arm, atrophy of shoulder and upper arm muscles: two sinuses, with edges undermined, at inner anterior surface of arm, near border of axilla, into which a probe passes toward the joint four inches, touching bare bone. Joint motion in all directions limited, almost completely, by reflex spasm.

April 21st.—Patient etherized; joint motion free in all directions, producing grating sensation. The joint was then laid open, a quantity of pus evacuated, the head of the humerus excised, half an inch more of humerus removed, glenoid cavity scraped out, cavity cleansed with 1 to 20 carbolic solution and peat dressing applied.

Dr. Ridlon presented the specimen with reference to two points: First, the futility of opening abscesses connected with osteitis in a joint before the walls have become very thin. He believed it to be best to either wait in this way or allow the abscess to open spontaneously. In cases which had been left to themselves, he had seen the abscesses disappear entirely. Or when they had been left to open themselves, and the patient received ordinary good food and tonic medicines, the discharge began to diminish, as a rule, in the course of six or eight weeks, and in the course of three months was only slight.

The second point was the fact that it was very easy to make a mistake where there is no motion at the joint in supposing that there is ankylosis, and it is injurious to give ether simply as a diagnostic test, because in these cases where the head of the bone and the cavity in which it rests are bare, and the surfaces are covered with granulations, such a procedure cannot do otherwise than make the joint worse.

DR. RIPLEY asked concerning the age of the patients and the joints included in Dr. Ridlon's statement.

DR. RIDLON said he referred to cases of osteitis of the hip, knee, ankle, wrist, and elbow, and to cases of Pott's disease; in other words, he would make the restrictions quite general. In some cases, of course, the abscesses may be pointing in unfavorable situations, and it may be desirable to make a counter-opening to turn the discharge in some other direction.

DR. RIPLEY thought that abscesses of the different joints, particularly of the ankle-joint, were most successfully treated by opening them, and establishing free drainage. Bryant, of London, had advocated free opening into joints for inflammation, and had reported most remarkable success, especially in young subjects. With regard to the question of examining patients' shoulder or other joints under ether in cases of suspected disease of the joint, he would say that, despite the temporary lighting up of new inflammation, it was the proper mode of treatment to be adopted. The first thing to be secured in surgical and medical practice was a correct diagnosis, and if ether was necessary to accomplish this, it should be administered. He thought that the restrictions mentioned must be taken with considerable modification.

DR. RIDLON remarked that Dr. Ripley's statement did not apply to the view he had intended to express. He did not wish to object to opening into joints, but simply to express the opinion that with abscesses connected with joints the patients were better off when *as abscesses* the swellings were let alone than when opened.

As to the administration of ether for purposes of diagnosis, it certainly was justifiable if diagnosis could not otherwise be made, but it seemed to him, however, that in all cases where there was osteitis to any great extent, giving rise to a condition which resembled that found in hip-joint disease, it was unnecessary to give ether for the purpose of making a differential diagnosis.

DR. RIPLEY remarked that so far from being correct was the last statement made by Dr. Ridlon, that a few years ago a child, brought from the South, was seen by one of the most prominent surgeons of the city of New York, now deceased, and whom all respected, who refused to make a diagnosis without not only etherizing the patient, but cutting into the joint. He wished simply to emphasize the point, that if the joint be manipulated with care, the patient being under the influence of ether, and subsequently being kept quiet, certainly no permanent evil is likely to result.

THE PRESIDENT expressed himself as being somewhat surprised with regard to the restrictions announced by Dr. Ridlon, inasmuch as it had been regarded as a correct rule in surgical practice to evacuate pus wherever it could be found. Of course there might be some particular contra-indications with regard to not only these cases, but also with reference to resorting to anæsthetics for the purpose of making a differential diagnosis. He was sure, however, that he had opened joints and evacuated pus in several cases with good results, and he had also broken up adhesions around joints at different times without any bad results.

DR. RIDLON said, according to his experience in the orthopædic department at St. Luke's Hospital, that in the cases in which the abscesses had been opened the joint had discharged more profusely, and for a longer time, and the patient had grown weak more rapidly than where under similar conditions the opposite course of treatment had been pursued. The statement which he had made was simply the result of observation, and not the result of any theorizing. During the last two years he had had under observation probably between two and three hundred cases.

DR. RIPLEY asked what the ultimate result had been, so far as the joint was concerned, when treated according to the method suggested.

DR. RIDLON replied that sooner or later, in the majority of cases, the patients recovered with ankylosis, and the condition of the joint had never been seen; and in most cases which terminated fatally it had been impossible to obtain an autopsy.

THE PRESIDENT remarked that even in cases of cold abscess it had been customary to evacuate the pus and hyper-distend them according to Callender's method, and that good results had been obtained.

DR. RIDLON referred to a case which came under his observation at St. Luke's Hospital, in which an abscess

accompanying hip-joint disease was opened as soon as it became quite prominent, pus was evacuated, the cavity was thoroughly distended with carbolic solution, and a Lister dressing applied in its most thorough detail for about three months and a half; the discharge never being allowed to be exposed to the air. This was in the autumn of 1878, and the sinuses are still open and discharging.

Considerable discussion then followed concerning the indications and contra-indications for surgical interference in joint affections, especially with reference to operations when there is evidence of waxy change, involving the liver and kidneys and other organs. The prevailing sentiment was that resection and other surgical operations were justifiable even though there was evidence of waxy degeneration of the kidneys and of the liver, because in quite a large number of cases good results had followed operations performed under these circumstances.

The Society then went into executive session.

MISSOURI MEDICAL ASSOCIATION.

Twenty-sixth Annual Meeting, held at Jefferson City, Mo., May 15 and 16, 1883.

(Continued from p. 548.)

DR. E. M. NELSON read, on Wednesday evening, by special appointment, a brief

SKETCH OF THE LIFE OF DR. JOHN T. HODGENS, whose death occurred so shortly before the last meeting that no opportunity was afforded for the preparation of any biographical sketch. As a token of respect to the subject of the sketch the vote referring the paper to the Publication Committee was taken by standing.

DR. SCHENCK, of St. Louis, read a very interesting paper comparing

VITAL AND HEALTH STATISTICS OF THE MALE AND FEMALE SEX,

and showing that female lives are in reality better risks for life insurance than are male lives.

A lady was here introduced and permission granted to her to speak to the Association upon

THE SUBJECT OF TEMPERANCE, she being a representative of the Sons of Temperance.

DR. ALLEN, of the Special Committee on Conference with Kansas and Illinois Associations, reported a motion

CHANGING THE DATE OF THE ANNUAL MEETING from the third to the second Tuesday of May, so as to allow delegates from this Association to attend the meetings in the adjoining States, both of which meet on the third Tuesday.

A resolution was also passed for the appointment of delegates to those meetings.

DR. N. W. HARRIS then read a paper on

GLAUCOMA,

recounting the history of his own case, the doctor's vision having been so impaired that the paper was read for him by DR. PREWITT.

Another paper on the same subject was read by DR. TIFFANY, of Kansas City. This was illustrated by colored drawings which were placed upon the wall behind the reader.

On Thursday morning DR. DICKENSON, the Corresponding Secretary, reported the receipt of copies of the "Transactions" of North Carolina and Minnesota State Societies. It was ordered that all papers offered by gentlemen not present in person to read them, be read by title and referred to the Publication Committee.

DR. ALLEN then read the

PAPER ON ALCOHOL,

which he was directed at last meeting to present at this time. A committee of three was ordered to be ap-

pointed to investigate and report at the next meeting with reference to the relations of alcoholism, insanity, and crime.

The following papers were read by title: "Injuries to the Head," by Dr. R. F. Brooks, Carthage; "Case of Congenital Encephaloma," by Dr. J. H. Duncan, Columbia.

The special order of the day was then taken up, and the following officers elected: *President*—Dr. E. H. Gregory, of St. Louis; *Vice-Presidents*—Dr. O. A. Williams, of Morgan County, Dr. John H. Duncan, of Boone County; Dr. J. D. Griffith, of Jackson County; Dr. T. J. Norris, of Macon County; Dr. C. H. Hughes, of St. Louis. *Recording Secretaries*—Dr. A. H. Ohmann Dusmenil, of St. Louis; Dr. D. V. Wales, of Jasper County. *Corresponding Secretary*—Dr. N. F. Essig, of Clinton County. *Treasurer*—Dr. C. A. Thompson, of Cole County.

THE NEXT MEETING OF THE ASSOCIATION

will be at Sedalia.

A resolution was adopted approving the record of the National Board of Health, and urging upon Congress the appropriation of necessary funds for the efficient work of this Board.

MISCELLANEOUS PAPERS.

DR. N. M. BASKETT read a paper entitled "Some Suggestions on Sanitation."

DR. W. A. HARDAWAY read a valuable paper reporting ten years' experience in the use of electricity in the treatment of diseases of the skin.

DR. T. E. POTTER, of Cameron, read a paper entitled "Therapeutics of Ergot and Ergotin in the Reduction of Spleen and Fibroids of the Uterus."

DR. C. A. TODD, of St. Louis, read an abstract of a paper on

ANTISEPTIC TREATMENT OF SUPPURATIVE OTITIS BY THE DRY METHOD.

The dry method consists in cleansing the ear with absorbent cotton, and applying an antiseptic powder. No syringing is allowed; no drops are instilled. This treatment was first published by Dr. Todd, in a paper presented to this Association in 1880, after he had tested it for some time, and fully demonstrated its value in his aural clinic at the Missouri Medical College. Dr. Todd was the first to recommend the use of borax as an antiseptic powder instead of boracic acid, and other insoluble or slightly soluble powders.

DR. W. P. KING, of Sedalia, read a paper on "Vaginitis," detailing seven cases which he had treated. He regarded the affection as purely local, and believed that the excision of carunculae myrtiformes would be curative in almost all cases. In the discussion upon this paper Dr. Schenck took the position that several of the cases reported by Dr. King were not cases of vaginitis as defined by Dr. Sims, but merely hyperæsthesia of the vulva, dependent upon local inflammatory conditions.

The following papers were then read by title: "Report on Malarial Diseases in Children," by J. P. Kingsley, M.D., St. Louis; "Intestinal Obstruction," by J. Geiger, M.D., St. Joseph; "Report on Railroad Injuries," by F. M. Johnson, M.D., Kansas City.

The usual votes of thanks were passed to citizens, Committee of Arrangements, the railroads, the press, and the retiring President.

The Association then adjourned for one year.

TASTELESS MEDICINES.—An old colored man saw a sign in a drug store which read "Tasteless Medicines." Looking in at the "pizenmixer," as he called him, he said: "Dat am de bes' advice I ever got—taste less medicines," and hurried away, just in time to dodge a package which was thrown after him.

ILLINOIS STATE MEDICAL SOCIETY.

Thirty-third Annual Meeting, held at Peoria, Ill., May 15 and 16, 1883.

(Continued from p. 548.)

THE report on obstetrics was read by Dr. E. L. Herriott, of Jacksonville, with supplementary reports by Dr. G. W. Jones, of Danville, and Dr. E. A. Ingersol, of Canton. The report was discussed by Drs. Holton and Corr. The report on ophthalmology was presented by Prof. S. J. Jones, and supplementary report by Dr. McKinney, of Barry.

In the report on ophthalmology the results of examinations of Chinese and Japanese showed them to be peculiarly exempt from the defect of color-blindness. The discussion on ophthalmology was participated in by Dr. G. W. Jones, of Danville, and Drs. Crawford and Tilley.

Volunteer papers on miscellaneous subjects; nominations, and votes of thanks constituted the closing session. The miscellaneous papers were read by Dr. J. Murphy, of Peoria, Dr. L. G. Thompson, of Lacon, and Dr. Reber, of Shelbyville.

DR. N. S. DAVIS expressed the feeling of dissatisfaction which has always existed among those who have had to report on the practice of medicine from the want of reliable data from which to base conclusions, and moved that the chairman be requested to appoint one member from each county to obtain and furnish such data to the Committee on the Practice of Medicine.

A special vote of thanks was tendered to Dr. J. H. Hollister for his twenty years of faithful and efficient service as Treasurer of the Society.

The Committee on Necrology requested the privilege of correcting the statement that no deaths had occurred, the corrections will appear in the "Transactions."

The retiring President, who was not relieved by the President elect, gave a brief address in response to a vote of thanks, and the meeting adjourned to meet in Chicago, May, 1884.

A CONFIDENT CORRESPONDENT.—Dr. J. O. Davy, of Springfield, O., is safe in prophesying the following: "In one of the February numbers of the *Medical Age* is an article on typhoid fever, in which the writer gave expression to the following sentiment: 'Typhoid fever is a disease which is uncontrolled and uncontrollable, and any one who says he can abort an attack or cut short the disease after it has passed the forming stage is either a knave or a fool!'

"Has not the doctor placed himself in similar situation to the animal that attempted to make a sky-rocket of a locomotive? Well! the result was in no way commendable to the animal for his judgment. It is very true the medical profession of the world of to-day regard the sentiment quite correct and endorse most heartily his strong diction, but all that will not prove the truthfulness of his assertion any more than the maledictions which were hurled at Galileo proved that the world was flat. A thing may be regarded impossible to-day and next year quite practical. Within the next five years typhoid fever will be controlled almost as easily as remittent or marsh fever of to-day. A patient can be gotten into a convalescent condition in from four to six days after the following symptoms are fully developed: temperature, 105°; pulse, 100 or 120 per minute; the nervous symptoms with delirium well marked; tongue, dry, cracked; articulation, quite indistinct; bowels, tympanitic, tender, and gurgling; diarrhea of ochre-colored stools, etc. Ninety per cent. of such cases can be gotten up and about their rooms in from twelve to eighteen days by proper medication. Fully ninety per cent. of cases of typhoid fever can be aborted if medication is properly commenced before the patients take to their beds. True, this sounds like the prattle of one suffering from mental hallucinations, but time will tell who are in the fog."

Correspondence.

A CASE OF WANDERING NEEDLES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR : The following brief account may be somewhat interesting as illustrating the behavior and one of the varied courses taken by foreign bodies introduced into the gastro-intestinal tract.

R. V—, thirty-three years of age ; seamstress by occupation ; born in Switzerland ; was first brought under observation one year ago, at the State Emigrant Hospital, Ward's Island. When admitted to that institution she had been suffering from acute colicky pains for the previous three or four weeks, referred to the lower part of the abdomen and the vagina, and in consequence was unable to assume an erect position or walk, except with marked increase of the pain.

Upon examination a narrow body about two inches in length was discovered imbedded in the abdominal wall, one inch below the umbilicus and somewhat to the left of the median line, fairly movable among the surrounding tissues and causing great pain when manipulated ; vagina exquisitely sensitive to touch, and examination on this account not admissible.

Signs of inflammation shortly appearing, with increase of the symptoms, the patient was etherized, antiseptic precautions taken, and the body cut down upon and removed by Dr. George M. Tuttle. It proved to be an ordinary sewing-needle, about one inch and a half long, slightly rusted, black and oxidized, lying one-half inch below the surface, in the substance of the rectus abdominis muscle.

The symptoms now subsiding, appeared again shortly afterward, the pain being referred to the left inguinal region, from which situation two others were removed at different times, however, but both lying parallel to, and close to Poupart's ligament. After this nothing more was discovered, although when discharged slight abdominal pain still remained.

Patient was admitted to the Mount Sinai Hospital in February, 1883, one year after the above ; one needle, it is said, having been removed in the meantime at one of the city dispensaries. With this exception there had been comparatively little discomfort till within the preceding two weeks, during which time she had suffered from constant vomiting, with severe epigastric pain, having taken little or no nourishment.

When admitted, her general condition was very poor. Pulse imperceptible at the wrist ; respirations hurried and irregular ; extremities cold ; temperature normal ; general abdominal pain complained of, and tenderness in this region well marked. Other examination negative with the exception of slight enlargement of the liver ; vomiting occurred several times. Patient sank rapidly, and died eight hours after admission.

Autopsy showed fatty liver to have caused death. Movable kidney upon the right side was also present. This could be displaced, anteriorly, to the median line, and below as far as the crest of the ilium. Imbedded in the great omentum, opposite the umbilical region, were found six needles, and likewise in the omentum, opposite the lumbar region, two were discovered. These, measuring 39 mm. in length, were blackened and corroded. The sharp points had disappeared, and they were firmly fixed, evidently surrounded by some inflammatory products, which had served to encyst them in their new situation. One needle had made its way through the parietal peritoneum and lay partly imbedded in the rectus abdominis muscle. Here the omentum was firmly adherent to the anterior abdominal wall, showing that some adhesive inflammation had accompanied its perforation of the parietal peritoneum and omentum. In the pelvis, over the femoral ring, upon the left side, the border of the omentum, which extended down to this region, was thickened by old inflammation,

and firmly adherent to the peritoneum of the pelvic wall. Two needles were here met with, which had found their way through the peritoneum in part, and projected into the substance of the psoas and iliacus muscle. Everywhere the needles presented the same corroded appearance, and could not be disturbed from their position without positive laceration of the surrounding tissues.

Nowhere were there any signs of recent inflammation. As to the exact length of time the needles had been present but little definite knowledge could be ascertained. One, however, is known to have been swallowed about six years ago.

Three years since, the patient was in the service of Dr. Pastolozzi, of Zurich, during which time a needle was removed by incision (one having been previously pressed out with the fingers). Similar symptoms were presented, and relief likewise obtained after removal. At this time it was learned that epigastric pain and oppression had been prominent since her nineteenth year, with also the occurrence of frequent vomiting, the vomited matter frequently containing considerable blood. Menstruation had always been regular, and there seemed to be no connection between it and the attacks of pain, the latter occurring at intervals of from eight days to two weeks, and lasting from one to two hours.

In all, therefore, it seems that six needles were removed ; the first at least three years after one was known to have been swallowed ; the last somewhat over two years later, and these are all described as being similar to those found on autopsy.

JOHN VANDER POEL, M.D.,
House Physician, Mount Sinai Hospital, N. Y.

Navy News.

Official List of Changes in the Medical Corps of the Navy for the week ending May 19, 1883.

CORWIN, WILLIAM A., Surgeon. Detached from the Receiving Ship Colorado and granted sick-leave for three months.

CRAWFORD, M. H., Passed Assistant Surgeon. Detached from the U. S. Ship Pinta and ordered to the Navy Yard, League Island, Pa.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending May 22, 1883 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
May 15, 1883.....	0	5	132	4	163	39	0	0
May 22, 1883.....	4	4	128	8	170	41	0	0
Deaths.								
May 15, 1883.....	2	4	30	6	25	19	0	0
May 22, 1883.....	0	1	32	7	27	14	0	0

The total mortality for the week ending May 19, 1883, was 728, of which 70 were from pneumonia.

ON EXTRACTING DECAYED TEETH AS A PREVENTIVE, OR CURATIVE EFFECT OF ILL-HEALTH.—Dr. G. W. Brandon, of Milford, Neb., writes : " In looking over THE

MEDICAL RECORD of May 12th, I see a communication from Samuel Sexton, M.D., of New York. In speaking of the extraction of decayed teeth, or teeth that from any cause are suffering from death of the pulp, I, too, have noticed the bad effect produced upon the system, in one instance that I recall, especially.

"Mrs. S. J. W.—, a lady about thirty-four years old, who had always enjoyed the best of health previous to her present trouble, was suffering almost continually with neuralgia (facial), also dyspepsia, and, as she termed it, sick headache and nervous prostration, loss of sleep, irregularity of the bowels, etc., etc., so bad that she was compelled to keep her bed for days at a time. She had employed several physicians, but realized no benefit from treatment, only temporary. She finally drifted into my office. Upon examination, I could detect no constitutional disturbance that I could attribute her trouble to. But upon noticing her foul breath I requested an examination of her teeth, which I found in a bad condition, several rotted down, others with the gum falling away, and so on. I requested her to have the offending members removed. She objected, said it would hurt, and went to another physician for treatment, but eventually returned, when upon reassuring her it would be a great help, she consented to the operation. I extracted all irritated or irritating teeth, when she asked me if I was not going to prescribe for her. I informed her I was not. I saw her some three months after, when she informed me that since the operation she had enjoyed splendid health, and had suffered less in the three months last past than she had any one day for five years previous, said her health was never better; at the same time showing me another tooth that was slightly decayed, said it did not ache, but no more bad teeth for her, and requested me to extract it, which I did. Now, I do not presume to say all cases will be as decided as the one just mentioned, but I do believe that in a great many cases we can relieve disease and do justice to our patients, as well as the profession, by considering these small but none the less aggravating conditions."

VITAL STATISTICS IN WISCONSIN.—The State Legislature of Wisconsin has passed a law requiring the organization of health boards and appointment of local health officers throughout the State; also the compulsory notification, by physicians, of contagious diseases. Active measures are being taken by the Secretary of the State Board to carry the law into effect.

"A NOVEL MODE OF CLEANSING THE VAULT OF THE PHARYNX."—Dr. J. O. Webster, of Augusta, Me., writes: "A paper with the above title, in THE RECORD of April 28th, leads me to report my own case. I can easily, with the tip of my tongue, sweep the entire vault of the pharynx, insert it for some distance into the posterior nares, and slightly into the mouths of the Eustachian tubes, and am in the constant habit of dislodging mucus by its means. This power I gradually acquired when a boy, by trying to dislodge mucus from behind the soft palate with my tongue. This was at last accomplished, with great difficulty, but the tongue became daily more pliable, and can now be used as stated above. The frænum linguæ was never cut."

FRACTURE OF INTERNAL EPICONDYLE OF HUMERUS.—Dr. J. W. Pryor, of Lexington, Ky., sends us the history of the following rare case: "October 18, 1882, Willie S—, aged twelve years, while wrestling with a playmate fell with the right arm semiflexed behind the body (the position in which fencers usually hold the left arm), the internal epicondyle receiving the force of the fall, as proved by the manner in which the arm was held, according to the testimony of the lad, the ecchymosis proving his statement. He could flex, extend, supinate, and pronate the arm with perfect freedom and little or no pain. The small knuckle of bone was freely movable, and crepitus very distinct. I was positive the fracture

did not extend into the joint. I saw the case about an hour after the injury; there was no swelling at that time. Dr. Stucky, who saw the case, agreed with me that it was a true fracture, and not a diastasis of the internal epicondylar epiphysis. We put the arm in an elbow-splint, bandaging from the hand to a short distance above the elbow. The boy did not return to my office until the fourth day from the injury. I found that the mother had removed the bandage and that the elbow was slightly swelled and quite painful upon flexion. I directed the mother to keep up passive motion. At the present time (six months since fractured), the arm has perfect motion. The internal epicondyle is slightly displaced toward the hand and enlarged, showing there had been a large deposit of callus about the situation of the break."

MEDICAL SOCIETY OF NEW JERSEY.—The one hundred and seventeenth annual meeting of the above Society will be held in Congress Hall, Atlantic City, on Tuesday and Wednesday, June 12th and 13th, commencing on Tuesday at four o'clock P.M.—William Pier-son, M.D., Secretary.

PROFESSOR ROBERTS BARTHLOW, M.D., LL.D., of Jefferson Medical College, has been elected Dean of the College in place of Dr. Ellerslie Wallace, who has been forced to resign on account of ill health.

BROMIC ETHER IN WHOOPING-COUGH.—Dr. Squire recommends a solution of bromic ether in water (1 to 200) for administration in whooping-cough, as well as for angina pectoris and spasmodic pain.

A CASE OF POLYORCHISM was observed in Bulgaria, in a farmer eighteen years of age. There were three testicles, two being on the right in the scrotum, one above the other.

WHY SOME SUBJECTS ARE STUDIED SO MUCH.—Dr. Da Costa has said: "If one has not too much to do he writes a short paper on phthisis; if one has little to do he writes a long paper on phthisis; if one has nothing to do he writes a book on phthisis." The same writer says: "Gynecologists, as a rule, part their hair and their names in the middle, and never die until they have invented pessaries and speculums innumerable."

A MEDICAL EPIGRAM.—It was Garrick who wrote the epigram on Sir John Hill, viz.:

"For physic and farces
His equal there scarce is;
His farces are physic,
His physic a farce is."

READING BIOGRAPHIES.—Dr. B. W. Richardson, in recommending to students the reading of biographies, says: "A man who will begin as a student to learn the lives of great men of the past, and will pass from one life to another regularly until he has made as many of the great ones of the past his bosom friends as he can, will at all times be miles in advance of other men who have made no such friendships."

CHLORATE OF POTASSIUM IN ULCERATING EPITHELIOMATA, in fine powder, is said to yield excellent results when dusted over the surface of ulcers and ulcerating epitheliomata. The surface should be cleansed and the powder dusted thickly on twice a day. This, it is claimed, relieves pain and promotes healing.

CASTOR-OIL AND GLYCERINE.—A mixture, which is of an agreeable flavor and in which the nauseous smell of the oil is efficiently disguised, can be made thus:

R. Ol. ricini.....	3j.
Glycerini.....	3j.
Tr. aurantii.....	℥xx.
Tr. senegæ.....	℥v.
Aquæ, cinnam.....	5 ss.

This forms a beautiful emulsion, is easily taken, even by children, and if administered at bedtime will produce a gentle motion the following morning.

ANGULAR ANCHYLOSIS OF FEMUR AT THE HIP-JOINT.

TREATED BY SUBCUTANEOUS DIVISION OF THE SHAFT AT THE TROCHANTER.

BY STEPHEN SMITH, M.D.,

PROFESSOR CLINICAL SURGERY, UNIVERSITY MEDICAL COLLEGE, NEW YORK.

THE patient was a young lady who suffered from disease of the hip-joint in early life, which resulted in ankylosis at an angle of about forty-five degrees. A year or two previous she had been under the care of the late Dr. James R. Wood, who endeavored to straiten the limb by force, but did not succeed. I gather from her statement that he did overcome the flexion somewhat, but that fact is not clearly made out. At the time when she first applied to me there was no perceptible motion obtainable at the joint, on the most careful trial.

The operation proposed was division of the femur just at the small trochanter, and the method selected was subcutaneous section with the fenestrated canula saw of

Dr. Geo. F. Shrady. This saw has great advantages over any other form of bone-saw in this, that by working in a canula, the tissues beyond the bone are not liable to be injured by the point of the saw as it is moved backward and forward. The saw is described as follows by Dr. Shrady :

The instrument consists of a trocar, fenestrated canula (Fig. 1), and a staff (Fig. 2), with handle and blunt extremity. A portion of this staff at a short distance from the extremity is flattened, one edge (*B*) being made into a knife-blade, and the other edge (*C*) being provided with saw-teeth. This staff (Fig. 2) is intended to replace the trocar in the canula after the latter is introduced. When in position (Fig. 3), either the saw (*C*) or the knife (*B*)

edge of the shaft, according to the way the latter is turned, corresponds with the opening in the canula. The saw or knife can then be worked to and fro within the canula by a piston-like movement, the canula being steadied by grasping the flange (*D*) at its base. If it be necessary to work the instrument as an ordinary blunt-pointed sheathed saw or knife, the shaft can be fixed in the canula and made into one piece by a thumb-screw in the handle. The portion of the canula at the back of the opening is made extra strong and is of the same thickness as the blade, so that in sawing there is no stoppage to the passage of the instrument through any thickness of bone. The soft parts are protected

from injury, no matter which way the instrument may be worked. The saw-blade is blunt at its extremity, and is guarded on all sides except on its limited cutting surface. The same may be said of the knife. The working of the saw to and fro in the canula is sufficient in sweep to insure the division of any bone having a diameter less than the length of the cutting edge. Still, as this process is much slower than when the saw is used in the ordinary way, it is perhaps better to restrict its employment to operations on the smaller bones, to cramped localities, and to situations where there is special danger of wounding some neighboring vessels. All that is necessary in using this saw is to thrust the trocar and canula into the limb, the fenestra of the canula being alongside of the bone upon which the operation is to be performed. The trocar is then withdrawn, the staff introduced in its place (Fig. 3) and worked as already described. The instrument is made of different sizes, to suit the different purposes for which it may be employed.

As one of the liabilities after the simple division of the bone is the displacement of the lower fragment from contact with the upper portion, so as to endanger non-union, I decided to attempt to overcome that tendency by making a half tenon and mortise by which the fragments would lock. This was easily effected by dividing the bone partially on the posterior and anterior surfaces, the incisions being separated half an inch or more, and

Fig. 4.

breaking the intermediate portion. The object sought to be accomplished is apparent from the following illustration (Fig. 4). Placing these two pieces in the position which the bone would assume after division, the relations of the fragments are shown in Fig. 5. If this

Fig. 5.

conception of the operation is applied to the case in hand the following illustrations (Figs. 6 and 7) will correctly represent the procedure and the results.

The operation was as follows : The left thigh being the affected limb, the patient was placed on her right side, which brought the left trochanter prominently upward. Selecting a point corresponding with the small trochanter, a sharp-pointed knife was introduced to the bone. Along the track of the knife Shrady's saw, sheathed in the canula, was passed, flatwise, until the blade of the saw was placed against the posterior surface of the femur at the point where section was to be made. The saw was then turned upon its axis so as to bring the teeth upon the bone. I attempted at first to hold the canula firmly, and work the saw in it, but found so much

difficulty that I finally worked the whole as a common saw. The difficulty of fixing the canula seemed to be due to my inability to hold the canula firmly (the instrument being without the extra handle, *vide* Fig. 8), and to a bending of the canula in the track of the saw when the saw was withdrawn, which interfered with its return. It is possible that particles of soft tissue were also drawn into the canula, which prevented the saw from returning along the track. The saw, however, worked satisfactorily with the canula to guard its point. After penetrating to a depth supposed to be a little more than half the diameter of the bone, the saw was withdrawn from the posterior surface and passed along the anterior surface, flatwise, about half an inch below the line of section of the posterior wall of the femur. Turning the saw to the bone, the section was made to a depth believed to be nearly on a line, in the long diameter, with the greatest depth of the posterior

Fig. 6.

Fig. 7.

section. This fact was determined by inserting two probes in the cuts. At this point I proposed to stop, and apply the plaster dressings, and break the intervening bone as the limb was brought down into the straight position. Some of the gentlemen present did not think that I had divided the bone sufficiently to insure fracture, basing their opinion upon the few movements which I had given to the saw. The truth was that the saw had cut the bone much more rapidly than they had supposed, for, on re-entering it, and making two or three passages, the bone separated in my hands.

The bone being divided while I held the limb, the assistants applied the plaster-of-Paris dressing. During the adjustment of the dressings, the lower fragment of the femur twice slipped out of its interlocked position with the upper fixed portion, but it was readily replaced, and when returned remained quite firmly in the notch prepared for it. The limb was brought into the straight position while the plaster was yet moist. It soon hardened, and then the dressings formed a splint, encasing two-thirds of both thighs, hips, and the lower half of the

body. A fenestrum was cut out at the seat of the wound of the thigh. The wound had been hyperdistended with carbolized water, and then hermetically sealed.

The patient did well for two days, when menstruation began with great nervous excitement, which induced restlessness, sleeplessness, apprehensions of danger, and loss of appetite. It was more than a week before these symptoms subsided, when a superficial abscess was found to have formed, which extended down the external part of the thigh nearly to the knee. It discharged freely through the original wound, and by means of compressed sponges, accurately applied and firmly bandaged, soon closed. It could not at any time be made out that the abscess penetrated to the divided bone, and from the rapidity with which it closed there can be no doubt that it was altogether superficial.

The union of the bone progressed satisfactorily, and in about the usual period which is required for the consolidation of a fracture at this point, the patient was able to get up, and begin to use her limb. She now walks without any support, erect as she would with a healthy limb, and with but a slight halt.

The advantages of this method of operation, if any, are: 1, The subcutaneous nature of the wound; 2, the precision with which the bone can be divided at the desired point; and 3, the definitely fixed position which the fragments necessarily assume with relation to each other immediately on the division of the bone.

The only embarrassment experienced was the effort to work the saw in the canula. Failing in this, the saw and canula were worked together, and, as the saw cut a groove sufficiently large to receive the canula, there was no difficulty in very quickly dividing the bone. The danger, however, of contusing the tissues on the inner side of the bone, by the end of the canula, is necessarily considerable, but in this case I am satisfied that the harm done did not interfere with the union of bone, nor the healing of the wound. Still it would be well to avoid the risk. On explaining the operation of the saw to Dr. Shady, he modified the canula by making the fenestrum so small as only to expose the teeth of the saw (Fig. 8). As the teeth cut a groove which the canula readily follows, the canula, thus strengthened, will enable the saw to work easily in it, and at the same time will follow the saw in its section of the bone. This saw seems to me now to be the perfection of its class.

Fig. 8.

A MODERN MIRACLE.—The *New Orleans Picayune* says that a medical man in New Orleans, who is fond of his little joke, called on a colored minister, and began to catechise him: "Why is it," said he, "that you are not able to do the miracles that the apostles did? They were protected against all poisons and all kinds of perils. How is it that you are not protected now in the same way?" The colored preacher responded promptly: "Don't know about that, doctor. I 'spect I is. I've taken a mighty sight of strong medicine from you, doctor, and I is alive yet."

CONVULSIVE AFFECTIONS IN CHILDREN AND THEIR TREATMENT.

By S. HENRY DESSAU, M.D.,

PHYSICIAN TO OUT-DOOR DEPARTMENT N. Y. FOUNDLING ASYLUM, DISTRICT PHYSICIAN TO N. Y. DISPENSARY, FELLOW OF THE ACADEMY OF MEDICINE, ETC.

CHILDREN, from infancy to the age of five years, are especially liable to convulsive attacks, and those beyond that age, when of a highly nervous organization, are frequently affected. This peculiar susceptibility to convulsions is supposed to be owing to the highly irritable nature of the growing cerebro-spinal system. It is moreover largely influenced by certain inherited tendencies, especially affecting the nervous centres, which act in the nature of predisposing causes.

Convulsions in children occur as a complication and often as a symptom of numerous diseases. They may also be produced by local-mechanical irritation. In general terms they may be said to depend for their primary cause upon an irritation of certain nerve-centres in the medulla, modified, perhaps, by a want of control on the part of certain inhibitory centres, which in the young child are not fully developed. This irritation may be produced directly by the action of the blood under certain conditions of quantity and quality, or indirectly through reflex transmission of peripheral impressions. The secondary or immediate cause may be said to be due to the peculiar susceptibility of the medulla to disturbance produced by the quality of blood flowing to it; and this may be influenced either by chemico-vital changes of that fluid occurring in the body at large, or by the quantity of blood supplied, which supply is controlled by the action of local vaso-motor mechanisms upon the heart and upon the calibre of the blood-vessels in distant parts. This quality consists in either an excess of carbonic acid or a deficiency of oxygen in the blood supplying the brain.

Convulsions produced in animals by the inhalation of carbonic acid gas are an illustration of the one, and convulsions from a large and sudden loss of blood an illustration of the other.

I therefore propose to arrange the convulsive affections of children under two grand divisions, viz.: those due to peripheral or local irritations, and those due to central or circulatory causes.

I do not recognize the class of convulsions in children commonly called essential, for where no assignable cause for their origin can be discovered, they are in all likelihood, especially when occurring after the third year, epilepsy.

Convulsions in children due to the influence of mental impressions may very properly be regarded as hysterical in their nature. There are certain sources of the local origin of convulsions that are of commoner occurrence than others. The most frequent one in the experience of every physician is irritation of the gastro-intestinal canal. This is the first cause generally suspected, in the absence of other well-defined and apparent causes, and will bear close scrutiny by the medical attendant. It is commonly due either to an improper quality or too great a quantity of food. More rarely it may be owing to the existence of entozoa, also a loaded condition of the rectum from constipation. Occasionally an intestinal catarrh, arising from sudden changes of temperature, may be the starting-point of the convulsion. Whatever combination of circumstances will lead to indigestion will, in all probability, excite a convulsive attack, the probability increasing with the acuteness of the stomachal disorder. This is, on account of the manner in which the contents of the stomach in children is hastened on into the intestines, where the undigested matter undergoes fermentation, producing gases and distention which excite pain. Occasionally matter which has been wholly unacted upon by the gastric secretions enters the intestines, where it causes mechanical irritation. I have met with a case of convulsions where large pieces of orange-

peel were detected in the passages from the bowels. Frequently the irritation proceeds from the stomach, before its contents have passed into the intestines. This occurred in the case of a boy, eleven years of age, whom I attended, where a quantity of sausage had been eaten, and was removed by an emetic. Trousseau mentions a case where the altered condition of the mother's milk, after she had passed through a state of mental excitement, was sufficient to cause convulsions in her infant, shortly after nursing.

It should not be forgotten that the process of dentition and the rachitic diathesis aid to a great extent as complicating factors in disturbing the function of digestion. This is beyond the part that they assume as independent elements in the causation of convulsions in children.

Dentition may be regarded as next in order of frequency as a source of local irritation causing convulsions in children. By dentition is meant the active process of the eruption of the teeth with the attending pain and general nervous erethism, consequent upon the swollen and congested state of the gum, when this exists. The condition of the nervous system that exists during the entire period of teething, which is dependent upon the alteration taking place in the various organs for a new departure of nutrition, can only be considered as a predisposing cause. There can be little doubt that dentition, as here implied, is a factor in the causation of convulsions, independently of any other element, for it has often been demonstrated on good authority that they have ceased as soon as the tension of the swollen gum was relieved by lancing. It has been disputed by some authorities on the diseases of children, notably Hensch, that dentition is as common a cause of convulsions as rickets. While I regard rickets as a prolific source of these attacks, as will be noted further on, there is little doubt in my own mind that, in the majority of cases of convulsions occurring in children suffering from rickets, it will be found that the active process of dentition is the exciting cause, the diathesis acting meanwhile as the predisposing cause. This view is rendered all the stronger from the fact that dentition, although retarded in rachitic subjects, occurs at the time when rickets is at the height of its morbid action.

There are numerous minor sources of local irritation exciting convulsions in children, amongst which can be enumerated, burns, scalds, blisters, severe itching from eczema or other cutaneous eruptions, hardened wax or other foreign bodies in the external auditory canal, foreign bodies in the nostrils, and in fact foreign bodies in any of the animal tissues. Trousseau relates one case where a long needle sticking in the brain and accidentally discovered by the thread attached, produced a series of convulsive paroxysms which ceased as soon as the needle was withdrawn; and another where convulsions had been caused by a needle found at the autopsy penetrating the liver. He also quotes Underwood, who records a case where a pin piercing the anterior fontanelle was found to be the exciting cause of convulsions, ending in death. Such substances as long hairs or pieces of thread found in the pharynx of young children, have been reported in the journals as the exciting cause of convulsive attacks. Dr. Buzzard in *The Practitioner* (vol. xx., p. 403) has ably demonstrated the mechanism of facial spasms produced by foreign bodies in the external auditory canal, and it is reasonable to infer that a similar degree of nervous disturbance from a like cause would be manifested in the young child by a convulsion.

Under the division made of convulsions due to changes in the quality and quantity of blood supplying the cerebral circulation, fevers occupy the first place in frequency and importance. All fevers are due either to a specific poison circulating in the blood, or to the process of congestion and inflammation. To the first class belong the eruptive fevers of children, such as scarlatina, measles, variola, varicella, and erysipelas, and typhoid and malarial fevers. Each of these may be ushered in by a convulsion

corresponding to the chill in the adult. In malignant cases, convulsions often occur some time after the fever has begun, probably from the action of the specific poison. Where this happens in the early stage of scarlatina and the late stage of measles, an unfavorable termination may be expected. Convulsions occurring during the latter stage of scarlatina, it need hardly be said, are of renal origin. Intermittent fever in children, especially in those having a convulsive predisposition, presents a marked illustration of the convulsion taking the place of the chill in the adult. All doubts as to the nature of the convulsion may be set at rest when it is found to occur periodically, and is followed by high fever and sweating. To the class of fevers arising from congestion and inflammation belong pneumonia, bronchitis, summer diarrhoea and its allied affection heat fever, tonsillitis, and other catarrhal affections. Pneumonia involving the apex of the lung is especially apt to be accompanied with convulsions in children. Vogel regards convulsions in children occurring where the disease is located in certain parts, as due to the reflex irritation of the diseased organ or tissue upon the nerve-centres.

It may frequently be observed that there is no direct relation between the rise of temperature and the manifestation of the convulsion, for in children of a nervous temperament, who are more susceptible to the action of the febrile process than others, a moderate rise of fever, as indicated by the thermometer, is sufficient to induce an attack. Gastro-intestinal irritation and the irritation of dentition are frequently attended with fever. But in such cases it seems reasonable to connect the rise of temperature with the same condition of the vascular mechanism as that exciting the convulsive attack.

Rickets and syphilis are included under the head of circulatory causes, producing convulsions in children, from the fact that in both of these diseases the process of nutrition is seriously at fault, owing either to an increased or imperfect metamorphosis of tissue, the blood necessarily becoming changed in character. It has been supposed by some writers that the frequent occurrence of convulsions in rickets was in consequence of the softened and elastic cranial bones not offering a proper support to the blood-vessels, so that an undue amount of blood reached the brain. Perhaps it may be well to regard this view as having a certain degree of importance in determining the rationale of convulsions in rickets, though certainly the condition of the blood supplying the brain cannot be slighted. This view becomes all the more tenable when rickets is compared with hereditary syphilis, which it closely resembles in many clinical and pathological features, and which is now well known to be frequently attended with convulsions.

Laryngismus stridulus is the common form of convulsive manifestation in rickets, and may be regarded as an integral part of the disease. It usually is the prelude to a general attack, if not speedily controlled. The interference with the normal oxygenation of the blood by the frequent spasmodic closure of the glottis, presents a marked illustration of the influence of venous stasis in the cerebral circulation producing general convulsions.

Children suffering from rickets are immensely subject to pulmonary and gastro-intestinal complaints. These, as well as dentition, frequently aid as exciting causes to produce convulsions in such children.

The influence of syphilis in producing convulsions in children may be regarded in many respects as similar to that of rickets. Disease of the cerebral blood-vessels, leading to hemorrhagic extravasations, is probably an additional factor.

In children affected with pertussis, convulsions are the result of mechanical interference with the return of venous blood from the brain, through spasm of the muscles of respiration. Here, as in laryngismus stridulus, the nervous organization is already in a highly irritable condition, and the nerve-centres are easily disturbed by the repeated venous stasis which occurs. Convulsions in

children occurring toward the end of summer diarrhoeas, are due to the anæmia caused by the excessive drain upon the blood. Those occurring in the latter stages of pneumonia and bronchitis are from an accumulation of carbonic acid in the blood.

In the early stage of tubercular and simple meningitis, cerebral hemorrhages, tumors, and other cerebro-spinal affections incident to children, convulsions are a frequent symptom. They are then probably due to changes in the cerebral circulation, depending upon irritation of local vasomotor mechanisms. Toward the end of these diseases, however, the convulsions may justly be attributed to changes in the quality of the blood flowing to the brain, the result either of imperfect aëration from irregular breathing, or venous congestion from mechanical pressures.

Every convulsion, however slight and limited, and from whatever cause, should be regarded as dangerous, owing to the tendency to paralysis of the vital centres in the medulla through exhaustive expenditure of nerve-force. Certain forms of the attack may, however, be considered more favorable in their termination than others. Such, for instance, are those occurring at the onset of febrile processes, where there is no complication with the rachitic or syphilitic diatheses nor dentition, and the paroxysms are not repeated. Where the attacks are general, soon over, and single, they have in my experience, proved less dangerous than where they are partial and long-continued. Carpo-pedal contractions should always be regarded as a danger-signal for the near approach of a general convulsive attack, and deserve prompt remedial measures. It occasionally happens that effusions into the ventricles of the brain follow a prolonged attack of convulsions, causing death from coma.

From the previously described etiology of convulsions in children, certain therapeutical indications may be deduced. These, in general terms, are to remove the exciting cause, if possible, assist in restoring the balance of circulation, and quiet the excited nerve-centres. For the proper operation of these measures the child should first of all be entirely undressed, if this has not previously been done, and held wrapped in a light blanket in the nurse's or mother's arms, in a good light. While this is being done questions concerning the kind of diet, character of the passages from the bowels, previous health, and other pertinent matters, can be rapidly asked. At the same time a careful inspection of the body and the cavities of the nose and ears for foreign bodies can be made. The gums should be examined, also the anterior fontanelle and occiput. The existence of fever and appearance of the skin, especially in the bends of the joints, should be noted for the eruption of scarlatina, and on the forehead and scalp for measles. Inquiry as to any complaint of pain, its seat and character, previous to the attack, should not be omitted. Sufficient information can thus be hastily gathered to base a reasonable method of procedure upon, examination of the lungs not being included, as nothing definite can be discovered thereby, owing to the accumulation of mucus in the bronchial tubes and irregular respiration.

In the absence of any known exciting cause—excluding epilepsy, which rarely occurs before three years of age, is without fever and followed by a more or less prolonged comatose stage—I have always considered it safe practice, especially where the convulsive movements continue, to suspect intestinal irritation; for I have found in several instances that it was possible for the child to have eaten something that the nurse or mother was unaware of or placed small importance upon.

The first thing to be done, therefore, intestinal irritation being the possible cause, is to administer an enema, which should consist of a pint or more of strong soap-suds with a teaspoonful of salt and a tablespoonful each of molasses and castor-oil. This I usually give myself, the suction end of the syringe, if a Davidson is used, being held by an assistant near the surface of the mixture, so that the

oil, as it floats on the surface, may be first thrown into the bowel. Where the enema does not appear to empty the bowels satisfactorily, it is advisable to give a brisk purgative by the mouth, such as three grains of calomel with five of bicarbonate of soda. This should not be given where an emetic has first been used, until the stomach has had time to rest. Besides unloading the intestines, the enema, by its stimulant properties, acts as a derivative in equalizing the circulation, and the calomel often has the effect of reducing temperature accompanying the intestinal disturbance, when due to other than the presence of undigested matter. If the convulsion occurs shortly after a hearty meal or the eating of any very indigestible substance, an emetic is first indicated. The syrup of ipecac or pulverized alum mixed with table syrup can be given, if at hand, or what I generally find more convenient and equally as effective and rapid in action, a draught of tepid mustard-water with salt. This can be administered by the spoonful successfully, with the exercise of a little knack and patience. If the physician carries with him a solution of apomorphia, one-fortieth to one-twentieth of a grain may be injected hypodermically into the buttocks. The emetic, besides emptying the stomach of its contents, in many instances aids, by its revulsive effect, in checking the convulsive movements.

Frequently it happens that the convulsions continue in a partial manner after the stomach and bowels have been emptied, even where their contents had provoked the attack. This may be owing to the impression that the irritation has left upon the nervous centres. In such a case the bath should be resorted to. And here there appears to be some diversity of opinion among eminent writers on the subject, as to the advisability of the warm, hot, or cold bath. As each may be used with equal propriety, where the occasion demands, it may be well to explain their action upon the cerebral circulation.

Schüller has demonstrated by physiological experiments performed upon rabbits, that the action of a full cold bath is to dilate the blood-vessels of the pia mater, contraction occurring only after a long application of the bath, and then from the blood being cooled down. The full warm bath causes powerful contraction of the vessels of the pia mater, often preceded by a transient dilatation. A very hot full bath produces dilatation, lasting longer, and only causes contraction after the bath has been cooled down to about 86° F. As is well known, the warm bath, of a temperature of 98° F. dilates the cutaneous capillaries, reddens the skin, and produces a general relaxing effect, while the cold bath contracts the cutaneous capillaries, and is attended with a certain amount of shock. A certain length of time is required for reaction to be restored after the cold bath, and even then with the aid of friction. The cold sheet or rub-down, as described by Winternitz in the *The Practitioner* (vol. xxi., p. 104), rapidly excites dilatation of the cutaneous capillaries when combined with friction or patting, and by pouring cold water over the sheet reduces temperature.

It has been stated that convulsions have been excited again by the application of the hot bath—98° F. to 112° F.—where used to check them. As will be seen by Schüller's experiments, this might readily occur where a congestion of the cerebral circulation already existed, more especially if the precaution was not taken to apply the cold douche or a compress to the head at the time of giving the bath. I have, however, never witnessed such an occurrence, but on the contrary have seen a persistent attack of convulsions from gastro-intestinal irritation cease, after complete immersion in a hot bath, even where chloroform had previously failed to control it.

The practical conclusions to be drawn from the above description of the effects upon the cerebral circulation of the warm, hot, and cold bath, are that the warm bath is indicated where there is reason to infer that a congested condition of the pia mater exists, the hot or cold

bath where there is anæmia. Neither should be used too long. In convulsions depending upon fever, where a high degree of temperature exists, also in summer-diar-rhea, the cold bath may be used with advantage, but I think the rub-down previously referred to, with the addition of cold water poured over the sheet, preferable. Hot compresses to the head are, at the same time, advisable in all cerebral affections associated with a condition of anæmia. I have found the cold douche—temperature 40° F. to 60° F.—applied to the spinal column, either while the patient was in the hot bath or immediately after, has proved of considerable service in checking some cases of convulsions.

It has become an established practice to administer an anæsthetic at some time during the convulsive paroxysm. Chloroform is the one most commonly used, as it acts quickly, and in children is harmless when carefully used. Many physicians are in the habit of using it before all other remedies; while others prefer using it after the measures previously mentioned have been tried. The proper method, in my opinion, depends upon the severity of the attack. If these are violent and prolonged, causing the face to become livid, and are frequently repeated, it is best and safest to administer chloroform in preference to using other means, providing there is no easily perceptible local cause of irritation originating the attack. Otherwise, I consider it better practice to remove the cause first, if possible, and if the attacks continue then to use chloroform.

Nitrite of amyl has been used by Dr. Williams of Boston (*Canada Med. and Surg. Jour.*, September, 1882) with much success in the treatment of laryngismus stridulus, and other writers have reported its use in the general convulsions of children. It has been generally regarded as a highly successful remedy in the treatment of the attacks in epilepsy for some years, and from its well-known physiological action I regard it as being eminently appropriate in the convulsions of children. From three to five drops should be poured upon a handkerchief and held close to the mouth until a general flush of the face and body appears. My experience with it in convulsions has been limited, but I am almost inclined to prefer it to chloroform.

Sedatives may be administered during the attack, or what is better, immediately after, in order to quiet the excitability of the nerve-centres and so prevent a recurrence. Chloral hydrate, either alone in the form of an enema of three to five grains in a half ounce of clear starch, or by the mouth, in combination with bromide of potassium in the proportion of one part of the former to two of the latter, is a favorite treatment, the dose being graduated to the age, and given every two to four hours, according to the urgency of the case. This treatment will be found of the highest service in convulsions depending upon dentition, the rachitic diathesis, or pertussis. Other sedatives, as belladonna in small and frequently repeated doses, tincture of musk, and oxide of zinc have been recommended. Sulphate of morphia, given hypodermically in carefully regulated doses, may also be used, and, especially in symptomatic convulsions, will be found advantageous. Such cases in the comatose stage may be recognized, according to Parrot (*The Practitioner*, vol. xxix., p. 451), by the fact that if the skin be pinched there will be a momentary dilatation of the pupil to two or three times its previous size. Ordinarily these convulsions are limited to one side of the body.

Where malaria is the cause of the convulsions it need hardly be said that quinia is the main remedy indicated to prevent a return of the attack. Cod-liver oil and the syrup of the lactophosphate of lime should be given where evidences of rickets exist.

Convulsions occurring in the late stage of scarlatina, in addition to the before-mentioned remedies, should be treated with the view of relieving the renal congestion. Dry cups to the kidneys, the hot-air bath, and the internal administration of spirits of juniper with bitartrate of

potash will be found useful remedies. Our knowledge concerning convulsive affections in children and their treatment may be formulated as follows :

All convulsions depend primarily either upon a peripheral or central irritation of vasomotor mechanisms, and secondarily upon a change in the quantity or quality of the blood-supply to the medulla for their causation.

Convulsions, from whatever cause and of whatever degree, involve an element of more or less danger to life, and should be treated promptly.

Where there is any doubt as to the exciting cause of the convulsions, it may be safely treated in the same manner as if from gastro-intestinal irritation.

The treatment should be directed to a removal of the exciting cause, if local, an equalizing of the general circulation and quieting of the excited nerve-centres.

75 WEST FIFTY-FIFTH STREET.

"CHLOROFORM NARCOSIS DURING SLEEP."

By DAVIS HALDERMAN, M.D.

PROFESSOR OF SURGERY IN STARLING MEDICAL COLLEGE, COLUMBUS, O.

IN THE RECORD of April 28th appeared an article by John H. Girdner, M.D., under the above title, wherein he takes the ground that chloroform narcosis during natural sleep is impossible; and goes on to speak in the following terms of how untrustworthy all previous experiments and testimony in this direction are: "As to the testimony of medical experts, I may say that I am not willing to accept their statements that a person may be chloroformed while asleep without being awakened, because the evidence on which they base this opinion is anything but conclusive. The few experiments which have been made by these experts were not reliable tests, because the parties on whom they experimented were aware that at a certain hour of a certain night the doctor would make the experiment, and a desire on the part of the subjects to have the experiment succeed may have been strong enough to tempt them to simulate narcosis." The doctor then, in support hereof, gives a series of five experiments, made by himself and another physician—all of which are minutely detailed, including the age, sex, etc., of the individuals experimented upon. One of these was a boy, aged eight; another, a girl, aged twelve; the others were adult males, aged thirty, thirty-two, and thirty-five, respectively. All of them were hospital inmates, and the experiments were performed "at twelve o'clock on the night of January 31, 1882, during a terrific snow-storm."

In each case, we are told, "the chloroform was poured on a folded towel and held eight inches from the sleeper's face," and that all awoke at the end of three minutes but one, and this latter at the end of two minutes; and further, that all of them, on arousing, were more or less frightened, tried to tear away the towel, coughed, gasped for breath, etc.

The doctor in effect claims for these experiments, (1) that they were undertaken "solely with a desire of arriving at scientific facts;" (2) that they were done under the most favorable circumstances to this end, the persons chosen for the purpose being of both sexes, and of a variety of ages, and withal were entirely ignorant of anything whatever being intended; (3) that he and his *confère* "had both had a large experience in the administration of anesthetics;" and (4) that they "took every possible precaution that no errors should creep into the results;"—requisites and conditions the doctor justly maintains to be necessary to the formation of correct conclusions.

He finally closes his article with these words: "These experiments must then be taken as *prima facie* evidence toward the establishment of the fact that it is impossible to transfer an individual from a natural to a chloroform sleep without an interval of perfect consciousness." Here we beg leave to take issue with the doctor, and shall give our reasons for so doing.

Out of three attempts, some years ago, at chloroformization during sleep, made by the writer, two were successful. The subjects of them were convicts in the Ohio State Penitentiary. The experiments were carried on at about half-past ten o'clock at night, in the presence of a number of medical gentlemen, and two of them in a room that lodged about one hundred and fifty sleepers. From this number these two were chosen, as it were, at random—so that even ourselves were not aware beforehand who they should be. The prisoners were here, of course, under strict surveillance, and could have had no idea whatever of our intentions, as no one had been told of them. The utmost stillness surrounded the occasion, save the heavy breathing of the sleepers, and their shifting, now and then, upon their hard and narrow couches. The gas-lights were turned down so as to shed a faint glare over the scene. It was under these circumstances that the first two tests were made, and in this wise: The chloroform was administered from a cotton cloth about the size of a common pocket-handkerchief, such as a burglar would likely carry. It was well saturated with the drug, and held, at first, as much as two feet from the sleeper's face; the object being to sparingly impregnate the atmosphere for some distance around him, so as to blunt, primarily, the air-passages, and thus avoid the liability of the reflex disturbance which must inevitably take place if the anæsthetic be given freely at the start. This done, the cloth was cautiously brought to the position ordinarily held, and kept there until the narcosis was complete. The patient was then handled and dealt with, so as to leave no doubt as to the result.

The next experiment was made in the same way, but failed. Both these were adult male subjects. The other was an adult female, who slept by herself in a cell, in a part of the prison devoted to that sex; her surroundings, too, were quiet. The anæsthetic was given as before, and with complete success.

Here, then, are two cases of chloroform narcosis effected during natural sleep, and under circumstances wherein all the conditions and requirements claimed by Dr. Girdner as necessary to insure reliable results, were fulfilled; for our sole aim, also, was to get at the facts.

The opposite results in the doctor's experiments were, doubtless, owing to his too great haste in the outset. The eight inches spoken of, as the distance the cloth was held from the face, was obviously too close for safety, the reflex action it must have occasioned would be almost sure to arouse the sleeper, unless he happened to be of exceedingly sluggish disposition, or slept uncommonly sound. Then, too, "the chloroform was poured on a folded towel," which leads us to infer that it was given in large quantity, so that the results, it is not too much to say, were just what might have been expected.

But the most singular thing in the doctor's experiments is that he did not somewhat vary them. Instead of conducting them all alike, one would suppose after failing in one way, he would be inclined to try another, and so keep on, until every mode and means were exhausted, to bring about the narcosis, before undertaking to proclaim, in such a summary manner, the impossibility of its accomplishment.

Nor are these results of ours the only ones in contradiction with the doctor's assertions. In an article on the Medico-Legal Relations of Chloroform (*Ohio Medical Recorder*, January, 1877), Dr. R. M. Denig quotes largely from a report of Professor D. Dolbeau (*Annales d'Hygiène*, 1876) made to the Medico-Legal Society of Paris, on the question: "Can chloroform be successfully administered to a person during sleep?"

In the experiments made by this gentleman, twenty-nine in number, including both sexes, and comprehending a wide range as to age and physical conditions, ten were completely successful, being more than one-third.

In deciding a question of such gravity as the one under consideration, it is hardly fair to ignore such an amount

of testimony—emanating, as it does, from such a competent source; and Dr. Dolbeau very justly concludes by saying that the expert is bound to admit, that although difficult, it is possible to induce chloroform narcosis during natural sleep.

Here are three more cases. In the *Pacific Medical and Surgical Journal* for January, 1874, may be found the two following cases: The first was that of a little girl, aged eight, under the care of Dr. Curtis for suppurative inflammation of the mastoid process. The doctor says: "Deeming it expedient to operate for the evacuation of the pus, we met at nine o'clock. On our arrival we learned that our patient had slept but little during the night, but was then sleeping sweetly. Chloroform was at once administered upon a 4 x 6 piece of surgeon's lint, held as near the child's mouth as possible without coming in actual contact. Not the slightest effort was made by the child to avoid the inhalation of the anæsthetic, and in a few minutes was well under its influence and was carried into an adjoining room, placed upon a lounge, and the operation completed.

In the second case the little girl, two and a half years of age, was brought to the hospital to have a supernumerary toe removed. While awaiting the arrival of Dr. Nelson, the child fell asleep, and was placed in the operating chair. As soon as the doctor arrived, chloroform was administered in the manner already detailed, with equal success, and the operation completed without the occurrence of an unfavorable circumstance.

This one is from Dr. Schauffler, of Kansas City (*Kansas City Medical Journal*, 1875), wherein the anæsthetic was given for the purpose of removing a foreign body from the nasal cavity, in a female child about four years of age. After relating the history of the case, the doctor thus continues: "Tired out as she was, the child soon went to sleep and was laid upon the lounge. I then began to administer to her the chloroform upon a handkerchief, and in the usual way. As I expected her to wake up, I observed no special precautions. To my great satisfaction, however, she did not awake, but passed very quietly under the influence of the anæsthetic. The pebble was now readily removed, and proved to be three-fourths of an inch long by half an inch wide, and one-fourth of an inch thick. The little patient continued to sleep for an hour or two, and then awoke feeling perfectly well."

Certainly no collusion, or "a desire to simulate narcosis," in any of these cases, can be suspected.

It is now felt to have been conclusively shown, first, that chloroform narcosis during natural sleep is not only possible but practicable; second, that the doctor's experiments were anything but satisfactory; as there was not exercised in their management that care and versatility of resource which would warrant the conclusions he promulgates, even though there were no evidence of a contrary character known, or on record; and, finally, that chloroform may be made use of for criminal purposes, but that its success in this direction must always be contingent upon the skill in its administration, and upon the disposition of the victim, as regards the nature of his sleep, whether it be sound or easily disturbed.

It is not to be presumed, of course, that all persons can ever be unconsciously chloroformed any more than that all banks can be robbed.

THE ORIGINATOR OF THE ARMY MEDICAL MUSEUM AND OF THE MEDICAL AND SURGICAL HISTORY OF THE WAR.—Dr. Wm. A. Hammond has obtained from the Adjutant-General of the Army a correction of the statement circulated in the general order announcing the death of Surgeon-General Barnes, and giving the deceased credit for originating both the museum and the library. Dr. Hammond adduces proof that he conceived and put into execution the plan of establishing a medical museum and of writing a medical and surgical history of the war.

"CHLOROFORM NARCOSIS DURING SLEEP."

By E. M. NELSON, M.D.,

ST. LOUIS, MO.

In looking over the columns of your journal for April 28th, my attention was attracted to an article with the above title by Dr. John H. Girdner, of New York. He concludes his article with these words: "While many will doubtless require a larger number of experiments before giving a decision, there are some who will see sufficient evidence in these five experiments to satisfy their minds that every experiment of this kind, made for whatever purpose, will have a like termination."

Now, while five negative cases may be a sufficient number on which to base an argument in the absence of any positive evidence, one well-authenticated case in which chloroform narcosis has been induced during sleep completely overthrows the argument.

In the evening of October 9, 1880, I accompanied Dr. A. J. Steele, of this city, to the residence of Mr. —, on Washington Avenue. A lad of about ten years of age was in bed sleeping soundly when we arrived. Chloroform was administered by pouring it upon a folded towel, and gradually bringing this nearer to the face of the boy. After about two minutes he became a little restless and turned a little in bed. The towel was removed a little farther, and then again gradually brought near to the face. Complete narcosis was obtained; the operation of circumcision was performed, a dressing applied, and the patient was sleeping quietly when we left the house.

I have no more faith than has Dr. Girdner in the authenticity of the popular reports of chloroform administration by burglars, and am in doubt whether chloroform can be as successfully administered to an adult; but that it can, in some cases at least, be successfully administered to children the case related conclusively demonstrates.

GARRISON AVENUE.

HINTS ON THE TREATMENT OF SOME PARASITIC SKIN DISEASES.¹

By GEORGE H. ROHÉ, M.D.,

PROFESSOR OF HYGIENE AND SURGEONS, BALTIMORE, MD.; CLINICAL DERMATOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE, MD.; MEMBER OF THE AMERICAN DERMATOLOGICAL ASSOCIATION, ETC.

JOHN HUNTER is said to have divided skin diseases into three classes: those that sulphur will cure, those that mercury will cure, and those the devil himself can't cure. Most general practitioners seemingly indorse this dictum of the great pathologist. At all events, most practitioners readily admit the difficulty of diagnosis, and the unsatisfactory results of treatment of many cases of skin diseases seeking relief at their hands.

When we reflect that ten years ago less than half a dozen of the medical schools of the United States made any pretence of giving instruction in dermatology beyond one, two, or three lectures, in the didactic course on the practice of medicine, which lectures were chiefly remarkable for the extraordinary number of uncouth words and unintelligible definitions hurled at the students, we cannot wonder that so many physicians should be unfamiliar with the diagnosis, causes, and treatment of the diseases affecting the skin.

In this paper it is proposed to consider, briefly, what appears to the writer the best treatment of some of the cutaneous diseases caused by vegetable parasites.

It is well known that the diseases known as *tinea favosa*, or favus, *tinea trichophytina*, or ringworm, and *tinea versicolor*, or "liver spots," are due to the presence upon or in the skin of microscopic organisms of vegetable origin. It would lead too far from the practical side of the subject to discuss here the botanical relations of these

¹ Read before the Clinical Society of Maryland, March 16, 1883.

three different parasites. For the present purpose it may suffice to state that clinically the diseases are distinct and easily differentiated, or rather, not at all likely to be mistaken for each other.

Favus is comparatively rare in the United States. The disease manifests itself in yellow, cup-shaped crusts, nearly always occurring upon the scalp. The crusts are perforated in the centre by a hair. If one of the crusts is removed, a cup-shaped depression remains in the skin, which gradually fills up to the normal level unless the crust is re-formed. The crusts of favus have a peculiar odor, said to resemble that of mice.

If a small portion of one of these crusts be rubbed up with a little liquor potassa, placed on a glass slide and brought into the focus of a one-fourth inch objective under a microscope, a number of transparent branched tubes (mycelium), with small spherical or oval bodies (spores) in their interior will be seen. Spores, singly or in groups, will also be seen in various portions of the field outside of the mycelial tubes. This is the fungus upon which the disease depends—the *achorion Schenleini* of Remak. The hairs which perforate the yellow crust or scab will also be found filled with these spores. The destruction of the fungus cures the disease by removing its cause, hence a paraciticide is the proper remedy to use.

It will be found, however, that all efforts at treatment will fall short of success unless all the crusts, and the hairs perforating them, are first removed. Soaking the scalp with oil or lard for twelve hours, then washing with warm water and soap to remove the crusts, and afterward pulling out the hairs from the diseased patches, are, therefore, necessary preliminaries to a successful treatment of the affection. After the crusts and affected hairs have been removed, the application of sulphurous acid, either in full strength or diluted with an equal quantity of water, or a solution of corrosive sublimate, one to three grains to the ounce of water or alcohol, will be all that is needed. The antiparasitic remedy must be kept constantly applied and the case carefully watched. If a relapse is threatened, prompt epilation and removal of the most primitive crusts must be practised. When favus has lasted a long time, baldness is likely to follow over the affected surface.

The time necessary to effect a cure of favus varies, but complete success should not be expected in less than six weeks to two or three months. The disease can be made to disappear in a much shorter time, but will almost certainly return if the parasiticide applications are not continued for at least three or four weeks after any evidences of the disease can be seen.

Ringworm presents marked differences as it affects different regions of the body. When it occurs upon the hairy scalp it appears in scaly patches, often having a small-vesicular or pustular border. The hairs upon these patches are dry, brittle, and most of them are broken off a short distance above the skin, giving the patches the appearance of a stubble field, over which the grass or grain has been irregularly cut. The skin under the scales is usually little, if at all, reddened, except at the border, where the disease extends centrifugally. This stubbly appearance of the hairs is characteristic of ringworm of the scalp. In that form of partial baldness termed *alopecia areata*, and which is also held by many to be parasitic, the bald patches are perfectly smooth, white, and shiny—altogether different in appearance from the scaly ringworm patches.

When ringworm remains for a long time untreated, or is improperly treated, it may develop into *kerion*, a curious, obstinate, tuberculo-furuncular disease of the scalp, which has been very thoroughly observed and graphically described by Dr. I. E. Atkinson, of Baltimore.¹ In *kerion* there is a condition simulating sycosis. The hair-follicles are inflamed, variously sized tumors develop,

from which exudes a gummy, honey-like fluid. The hairs fall out and the spot is likely to remain permanently bald—a result not apt to follow simple ringworm, in which the hair is almost always reproduced.

In ringworm of the scalp, cleanliness and frictions with carbolized oil have been almost exclusively relied on in the practice of the writer. The strength of the application used is one part carbolic acid to sixteen parts of linseed or olive oil. This should be applied in the following manner: After washing the scalp with warm water and soap, and drying, a little of the oil is poured on a piece of flannel, and rubbed into the diseased patch with smart friction. The friction drags out of their follicles the loosened hairs, and has an additional advantage in opening the mouths of the hair-follicles and allowing the remedy to penetrate deeper, and come in closer contact with the parasite, which gives most trouble when it has penetrated into the hair-follicles. This procedure renders systematic epilation with the forceps unnecessary, and so increases the comfort both of physician and patient. When the diseased patch has thus been well saturated with the carbolized oil, the rest of the scalp should also be rubbed with it, to prevent extension of the infection.

Sulphurous acid has also been used with great satisfaction in the treatment of ringworm of the scalp. It is used either in full strength, or diluted with a half, or an equal part of water.

No other measures have been found necessary in the treatment of simple ringworm of the scalp. Where *kerion* was present, the boggy tumors were freely incised, and carbolic acid ointment used as a constant application with a favorable result.

Ringworm of the body—*tinea circinata*—usually appears in the form of variously sized scaly patches, with a red papular, vesicular, or pustular border. It extends peripherally until the spots reach the size of a silver dollar, rarely getting larger without a break in the regularity of the margin. As it extends peripherally, the normal condition, barring perhaps a slight scaliness, is re-established at the centre. Auto-inoculation not infrequently takes place, and spots are found on different parts of the body. The microscope will differentiate it from *seborrhœa*, or localized patches of *eczema*. The best method of treatment the writer has employed is to apply, once or twice a day, pure sulphurous acid to the spots. No other remedy has given so much satisfaction as this in simple ringworm of the body.

Ringworm of the beard, in the majority of cases, does not advance beyond the condition just described as ringworm of the body. It is usually communicated through some of the shaving utensils used by the barber—sponge, brush, or towel. When early discovered and treated, the application of sulphurous acid will give general satisfaction. A solution of corrosive sublimate, one to two grains to the ounce, also leaves nothing to be desired. When it has lasted a long time, however, and produced the disease known as parasitic sycosis—pustules, tubercles, and abscesses of the bearded part of the face, with involvement of the hair-follicles—treatment becomes more active and complicated, and must be pursued with vigor and persistence, if a cure is expected or hoped for. In cases of sycosis all pustules, tubercles, or abscesses should be freely punctured, the face being gone over every day, or every other day. The hairs of all inflamed follicles must be extracted with the epilating forceps. The patient should shave daily, or at least every other day. An ointment of white precipitate, calomel (or what is probably better than either), oleate of mercury (five per cent.), should then be applied, and kept in contact with the diseased surface constantly. In addition, the reddened patches of skin between the pustules or nodules should be painted two or three times a week with a solution of carbolic acid, one part to four parts of alcohol.

Ringworm of the genito-crural region—called *eczema*

¹ Archives of Dermatology, January, 1881.

marginatum by Hebra—presents peculiarities which demand special consideration. In this affection the diseased part presents all the characteristics of eczema—intense itching, exudation, infiltration of the skin, etc.—but unlike an ordinary case of eczema, there is present a distinctly outlined border, and on careful microscopic examination, a fungus resembling, and probably identical with, the ringworm parasite may be discovered.

Eczema marginatum demands a somewhat different treatment from ordinary eczema and ordinary ringworm. We must endeavor to combat the inflammatory condition on the one hand, and destroy the parasite on the other. Hence the parasiticide employed must be one that is effective, while it produces the minimum of irritation. In many cases the application of sulphurous acid, followed by oxide of zinc or Hebra's ointment, will produce a prompt cure. In others, no good effect at all will follow. In some cases the continued application of an ointment containing one or two drachms of ammoniochloride of mercury will produce the effect desired. In cases accompanied by intense itching, and much local inflammation, the writer has obtained the most excellent results from the frequent application of a lotion of benzoic acid, 3j. to one pint of water. After the itching is controlled by this means, the eczema will usually get well under simple dusting with starch or chalk, and cleanliness. The benzoic acid acts as a parasiticide, and destroys the fungus while promoting the cure of the eczema by relieving one of the chief factors in its continuance—the itching.

Tinea, or pityriasis versicolor, called also "liver spots" in the vernacular, has been observed by the writer nearly as frequently as ringworm. It occurs in the form of brownish-yellow, slightly scaly patches and spots, limited to the parts of the body covered by the clothing. It is most frequently localized upon the chest, which is sometimes completely covered by a continuous sheet of the eruption. The borders are irregular, and roundish or irregular patches extend beyond with intervals of sound skin between. It sometimes extends down the arm to the wrist, and up on the neck to the collar-band of the shirt—the soap-line, as it may conveniently be termed. Beyond this line the disease is rarely, if ever, seen. The mildest parasiticide suffices to destroy the fungus which causes the disease; hence it is never found on parts frequently washed with water and soap. The remedy which, in the writer's hands, has been uniformly successful in curing the disease, is a lotion of hyposulphite of sodium in the strength of half a drachm to the ounce of water. The patient is directed to take a bath once a day, using soap freely. After the bath the affected spots are to be mopped with the parasiticide lotion. In a week the discoloration has usually disappeared. The remedy should be continued a week or two longer to prevent relapse. No other than this simple treatment is necessary in the majority of cases of tinea versicolor.

It is surprising to what an extent cases of tinea versicolor are treated for syphilis, hepatic derangement, or similar supposed affections of the internal organs. Patients are sometimes compelled to take mercury or potassium iodide for months, under the supposition that they suffered from syphilis, when the only trouble was that just described, which, when properly treated, yielded to local remedies alone in the brief space of two weeks.

No mention has been made in this paper of the employment of tincture of iodine, chrysophanic acid, and similar active irritants in the treatment of the cutaneous parasitic diseases. The excuse offered for the omission, if any be necessary, is that the writer has never had occasion to use them. Patient and intelligent application of the remedies before mentioned will, in most cases, be followed by success. Nearly all patients will likewise be better pleased if a colorless, non-irritant application be used, than if an irritant remedy, staining the skin, and not infrequently causing disagreeable complications, be applied.

CONVERGENT SQUINT CURED BY ESERINE.

By C. A. BUCKLIN, M.D.,

NEW YORK.

THE common form of convergent squint may frequently be cured during the *first few days* of its appearance by dropping into each eye a solution of the sulphate of eserine, one-half grain to three drachms of water, morning and evening.

It is successful in those cases where the disturbance in the relations between convergence and fixation are of a slight degree or are only temporary. A free discussion of the disputed causes of common convergent squint will be found in THE MEDICAL RECORD, vol. xvii., No. 21; vol. xviii., Nos. 4 and 16.

In the common form of convergent squint the child, owing to a disturbance between his power to focus both eyes for an object and his ability to fix his eyes *both* at this object, is unable to see distinctly. *Far-sighted* children require a much stronger effort of accommodation to see objects distinctly than children with normal or near-sighted eyes. Consequently its use is to be followed immediately by small doses of strychnia, and lurking diphtheria or malaria appropriately treated.

Where this will not cure the squint, proper lenses should be resorted to immediately, or a carefully performed tenotomy may save the vision of the deviating eye. The daughter of Dr. Dumond, of this city, had a convergent squint of several weeks' standing cured by the use of convex twelve lenses; the acuteness of vision of the deviating eye was restored, and also binocular vision, which was lost, has since been restored. This result was obtained after one of our best-known specialists had decided that nothing could be done but a tenotomy later in life for cosmetic effects.

The acuteness of vision in the deviating eye being usually lost as a result of the squint, I urge upon all practitioners of medicine not to allow a child to look cross-eyed for two days without attempting to do something about it. The use of the sulphate of eserine in the treatment of squint is original with me. It is only applicable during the first few days of the squint.

Condition favors greatly the development of squint. Probably ninety per cent. of squinting children see distinctly through their grandmother's glasses distant objects. This always means that they have a marked degree of *hyperopia*, which leaves but little margin of accommodative power over what is absolutely required to see objects distinctly with both eyes. Should a child in this condition have slight pareses of accommodation, or his health impaired from diphtheria or other causes, he must squint or go without seeing objects distinctly. Should he, from imitating another or in any other way, learn how to squint, he would be surprised and delighted to find that he was again able to see distinctly, and would not give up the device like another child who derived no benefit from squinting.

The use of atropine improves the squint while the eye is completely under its influence, but always makes the trouble worse as the effects of the drug begin to disappear. Eserine makes an improvement which will probably be permanent.

THE CARE OF THE INSANE.—At the meeting of the Medical Association of Central New York, held at Syracuse on the 15th of May, the report of the Committee on the "Care of the Insane" was read by its Chairman, Dr. Theodore Dimon, of Auburn, and after discussion was unanimously adopted. The following resolution was unanimously adopted: *Resolved*, In the opinion of this Association, the lunacy laws of the State of New York have been carefully considered and wisely framed for the management and treatment of the insane, and it is not so much needed that these laws should be changed as that healthy public opinion should give its support to their successful administration.

Progress of Medical Science.

PAROXYSMAL HÆMOGLOBINURIA.—Dr. J. Boas regards this as a disease *sui generis*, and distinct from any other form of hæmoglobinuria. He states that individual attacks are always caused by the cooling of portions of the integument, as of the hands, feet, nose, ears, etc. The intensity of the paroxysm is in proportion to the degree and duration of the cooling of the skin. The primary condition is that of destruction of the red blood-globules, and the passage of hæmoglobin into the plasma. The general symptoms are secondary. The cause of this increased destructibility of the blood-globules is difficult to determine. In some cases it may be attributed to syphilis, in others to intermittent fever. The destructive process is at first local, occurring in the part exposed to the action of cold. Thence it spreads into the general circulation. The treatment is to be based upon the etiology, when that can be determined.—*Deutsche Medicinal-Zeitung*, March 8, 1883.

RUPTURE OF THE SCIATIC NERVE MISTAKEN FOR FRACTURE OF THE NECK OF THE FEMUR.—Dr. Küster relates the following case in the *Berliner klin. Wochenschrift* of March 26, 1883: The patient, while walking, slipped and fell backward. He experienced a severe pain in the right leg and numbness of the foot, and was unable to rise. When seen the following day he was suffering intense pain in the limb, which was rotated outward and apparently shortened. Pain on pressure was most severe in the neighborhood of the hip-joint, where there was also a slight swelling. At the first glance, the case was apparently one of fracture of the neck of the femur. This diagnosis had been made guardedly by two other physicians, who had seen the patient shortly after the accident, but had made no examination on account of the agony which he was suffering. Dr. Küster could, however, obtain no crepitation, and, moreover, passive movements of the joint occasioned little or no pain. A diagnosis was made of rupture of the sciatic nerve, and was confirmed by the subsequent conduct of the case.

TREATMENT OF CHLOROSIS BY BLOOD-LETTING.—The cause of the want of success in the ordinary treatment of chlorosis and anæmia lies, according to Dr. Dyes (*Allgem. Med. Central-Zeitung*, March 24 and 28, 1883), in a misapprehension of the nature of these affections. Instead of the blood being thin and bright red in color, it is, he asserts, thick and dark colored. This error has arisen from the appearance of capillary blood as flowing from superficial wounds of the integument or in epistaxis. But this is only a colored fluid which filters through the capillaries, the general mass of the blood being too thick and viscid to pass into the smaller vessels. This viscosity is owing to the large proportion of white corpuscles, and upon it depend the characteristic symptoms of anæmia. The integument is pale and cold, and by reason of the disturbance of the peripheral circulation, congestions of the internal organs arise. The author regards as erroneous the idea that the white corpuscles are converted into red by the agency of iron, and he condemns this remedy as not only useless but harmful in the conditions under consideration. Anæmia frequently ensues upon recovery from acute affections, and is, according to him, due to the non-elimination of morbid matter from the blood in those diseases. Dr. Dyes advocates phlebotomy in acute inflammatory troubles, especially pneumonia and rheumatism, and laments that this practice has fallen into desuetude. The mistake of the older physicians was not, he holds, in blood-letting, but in the employment, in addition, of purgatives. The two procedures are in no way allied in their effects, but rather opposed to each other. For the

benefits accruing from the abstraction of blood are owing to the removal of the excess of white corpuscles, while the production of watery stools only increases the viscosity of the blood by withdrawing its serum. He does not think that simple loss of blood can ever produce anæmia. He never found this condition to exist in invalided soldiers applying for pensions, although many of them had been severely wounded and had lost great quantities of blood. In accordance with these views, therefore, the author discards iron in the treatment of chlorosis and anæmic conditions in general, and resorts to phlebotomy. The local abstraction of blood by leeches or wet cups does not fulfil the indications, as the capillaries only are depleted, and these, as stated above, contain only a colored fluid with but few white corpuscles. Within an hour after the withdrawal of from three to five ounces of blood from the vein, Dr. Dyes asserts that the hands and feet become warm and the patient is bathed in a healthy perspiration, showing that the disturbance of the capillary circulation has been removed. The appetite soon returns and the insomnia and nervous exaltation subside. The diet should be conformed to the instincts of the patients, who usually crave spicy and well-seasoned food and have a repugnance to more solid nutriment.

LYMPHANGIECTASIS AND LYMPHORRHAGIA.—A young woman who presented herself at the clinic of Dr. Paul zur Nieden gave the following history: When she was only nine years old she observed a dropping on the floor of a milky fluid, which the doctor said was leucorrhœa. Two days later she noticed numerous little vesicles, about the size of a pin-head, upon the labia majora, and at the same time the external genitals became swollen. The discharge was very profuse, but was lessened by confinement to the bed. Soon afterward she had an attack of hæmoptysis followed by pneumonia, and there was no further trouble with the genitals for several years. When her menses first appeared, however, the discharge began again. A milky fluid was exuded from the labia in such great quantity that at one time, she said, she collected over two pints in four hours. This was again controlled by rest in bed. When first seen by Dr. Nieden there was no spontaneous discharge, but the labia were studded with little vesicles, which exuded a white fluid on pressure. A small piece was excised from one labium, and for several days there was a flow from the wounded surface in considerable amount—five ounces in one night. The fluid was of alkaline reaction and contained only a few lymphoid cells, but very numerous fat-globules. Treatment consisted in the removal of portions of the labia with the galvanocautery.—*Deutsche Medicinal-Zeitung*, No. 7, 1883.

MORPHIA IN STRANGULATED HERNIA.—The reduction of strangulated hernia by the subcutaneous injection of morphia first employed by Dr. Philippe, of St. Maudé, may render excellent services. Consequently many practitioners in the country, where either the want of proper instruments or the prejudice or unwillingness of the peasants to submit to an operation are serious obstacles to be got over, adopt this method in almost every case, and rightly so, as the effects are sometimes marvellous. A country surgeon has just published a report of eight cases treated thus by him with only two failures. The taxis and all ordinary means failed, and colotomy seemed the only resource. Twice the reduction was impossible, and the patients having refused to be operated upon would have infallibly succumbed. In one case to which he was called everything was ready for the operation, the patient consenting, when he proposed to inject a quarter of a grain of morphia over the strangulation. A quarter of an hour afterward the hernia was reduced without difficulty. Sometimes the delay is longer, but the pain and vomiting ceases; hence the operation can be postponed without fear for some hours, when a new injection is made and often succeeds.

SPONTANEOUS FORMATION OF GAS IN THE BLADDER.—Dr. F. P. Guiard reports the following case in *La France Médicale* of February 10 and 13, 1883. A physician seventy-seven years of age, had suffered for a number of years from glycosuria, and also had a calculus, for the removal of which he had undergone the operation of lithotripsy three times and cutting once. For the past three or four years he had noticed an escape of gas from the urethra at the end of micturition, sometimes accompanied by a considerable report. The phenomenon was not always present, but was never absent for more than a few days at a time. Its occurrence was preceded by no peculiar sensations, and the patient could never tell before urinating whether it would be present or not. The gas was completely free from odor, and could not be of intestinal origin. Its passage occasioned no pain. The most thorough examination could not detect the smallest vesical fistula. Three other similar cases were discovered and carefully observed by the author. In one of them the urine, when first passed, was in a state of effervescence, which the patient likened to that of champagne. All of the patients were diabetic, and all of them had had instruments passed into the bladder for one reason or another. The author attributes this formation of gas in the bladder to a process of vinous fermentation in the saccharine urine. Germs had been found in the urine in two of the cases by another observer, but the author himself had never been able to procure the urine at the moment of the emission of gas, and could not state certainly that it contained the sugar ferment. He thinks it most probable, however, that the fermentation germs were carried on the catheters or other instruments which had been introduced into the urethra. He proposed to designate this condition by the term of diabetic pneumaturia.

CURE OF ABSCESES OF THE NECK WITHOUT CICA-TRICES.—Dr. Quinlan recommends the passage through the abscess of a fine silver wire, and the ends tied outside, when it will act as a drain. This must be done before the pus reaches the surface, when it is, say half an inch from the external surface. No poulticing or stuping must be used, and when the abscess is evacuated a compress applied. The procedure has never failed in his hands.

CHRONIC TUBERCULAR BLEPHARITIS.—At a meeting of the Société Médicale des Hôpitaux, in February, 1882, Dr. Gérin-Roze presented a patient suffering from pulmonary and laryngeal tuberculosis. The patient had also a granular ulceration of the palpebral conjunctiva, which was pronounced by the speaker to be tubercular. The correctness of this opinion was, however, doubted by several of those present. At a meeting of the same society in December following, Dr. Gérin-Roze announced that the patient was dead, and that a microscopical examination of the conjunctiva had confirmed his diagnosis. The lesion was limited to the mucous membrane, which was infiltrated with young cells and amorphous granules. Several of the sections showed very distinctly the tubercular granulations. They were perfectly round, about the size of the head of a pin, yellowish in color, and composed of granular tissue without giant-cells.—*L'Union Médicale*, March 4, 1883.

VERATRUM VIRIDE IN TYPHOID FEVER.—Dr. A. W. Nelson publishes the results of his treatment of typhoid fever by small repeated doses of veratrum viride (*Archives of Medicine*, April, 1883). He has administered this drug in every case of the disease occurring in his practice during the past decade, and has not lost a case. He states that under its influence the pulse and temperature are lowered and held within the limits of safety, the danger of intestinal hemorrhage is reduced to a minimum, and convalescence is not unfrequently established at the end of the second week. The dose given was one or two drops of the official tincture every hour.

PUERPERAL DIABETES.—A paper by Dr. Mathews Duncan was read before the Obstetrical Society of London, the author pointing out the distinction between the slight glycosuria of pregnant and suckling women and real diabetes, with its polyuria and large amounts of sugar. Physicians and surgeons were well aware of the dangers introduced into their cases by complication with diabetes. But the subject of diabetes complicating pregnancy and parturition had attracted almost no attention, and this probably arose from its rarity, which might be accounted for by the disease frequently destroying in women the sexual energies, as it is said to do in man.

The author had collected twenty-two cases in fifteen women, and they demonstrated the great gravity of the complication as respects both mother and child. Of the twenty-two pregnancies (including those ending prematurely), four had a fatal result soon after delivery. In seven of nineteen pregnancies in fourteen women, the child, after reaching a viable age, died during pregnancy. In two the child was born feeble, and died in a few hours, making an unsuccessful issue in nine of nineteen pregnancies. The histories showed that diabetes may intervene on pregnancy; that it may occur only during pregnancy, being absent at other times; that it may cease with the cessation of pregnancy; that it may come on after parturition; that it may not come on in a pregnancy occurring after its cure. They showed that pregnancy may occur in a diabetic woman; that it may not be appreciably affected in its natural progress and termination by the disease; that it is very liable to be interrupted by the death of the foetus.—*London Lancet*.

TREATMENT OF ULCERS WITH BISMUTH.—Dr. Truckenbrod reports a number of cases of varicose and other ulcers of the leg, cured by the local application of subnitrate of bismuth. The cases were seen at the Würzburg Policlinic. The bismuth in fine powder was dusted over the ulcer until a thin layer was formed, and then a simple roller bandage was applied; where there were varicose veins a rubber bandage was employed. The ulcers were usually healed in a few days.—*Centralblatt für Klinische Medizin*, March 24, 1883.

DIRECT TRANSFUSION FROM AN ARTERY INTO THE PERITONEAL CAVITY.—Drs. Corona and Cocco-Pisani report the following results of transfusion experiments made upon animals: 1, Pure blood, passed directly from a carotid artery into the peritoneum of another animal is entirely absorbed; 2, in small animals three ounces of blood had been entirely absorbed in five days; 3, the blood, until its disappearance, remains fluid in the peritoneal cavity; 4, the increase of hæmoglobin begins after twenty-four hours and continues for a certain indefinite time; 5, the animal suffers no injury on the part of the peritoneum or of any other organ.—*Centralblatt für Chirurgie*, March 24, 1883.

HYSTERICAL RAPID BREATHING, SIMULATING CARDIAC OR DIABETIC DYSPNŒA.—Dr. E. Mackey, in the *London Lancet*, February, 1883, draws attention to the little stress laid upon dyspnœa as a possibly hysterical symptom, and gives the notes of a case of a girl, aged seventeen, to whom he was several times called, as her friends thought she was dying. Dr. Mackey points out the diagnostic differences between hysterical and diabetic dyspnœa. In diabetic dyspnœa the attack comes on suddenly and with violence; the inspirations are deep; the air passes well into the lungs, but apparently does not oxygenate the blood; the attacks may recur several times, but finally the patient becomes unconscious. The duration until death varies from ten hours to three days. The respirations seldom exceed forty per minute, whilst the pulse is small, weak, and very rapid. In hysterical dyspnœa the respirations are eighty or even one hundred and twenty per minute, whilst the pulse is from sixty to eighty per minute, and the previous history of the case aids greatly in forming a correct diagnosis.

GENERAL ATROPHY FOLLOWING DIPHThERIA.—Dr. A. Cahn relates the case of a boy, fourteen years of age, who suffered from post-diphtheritic paralysis of the pharynx and œsophagus. After this had passed off, in spite of a nourishing diet of milk, eggs, and beefsteak, the patient began to waste away, until finally he became so emaciated as to seem on the point of death. A strict confinement to bed and the application of ascending and descending currents of medium strength to the spine brought about a cure after a considerable length of time. —*Deutsche Medicinal-Zeitung*, March 29, 1883.

PERFORATION OF THE AORTA BY A FOREIGN BODY IN THE CÆSOPHAGUS.—Dr. Desplats relates a case in which a sharp fragment of bone was lodged in the cœsophagus, about half-way down. An abundant hemorrhage occurred at the eighth day, which was arrested spontaneously. Thirty-six hours later it again set in and led to the death of the patient. The autopsy showed an ulceration of the cœsophagus with perforation of the aorta about an inch and a half below the junction of the transverse and descending portions. —*Revue Médicale*, March 24, 1883.

HYSTERICAL ANGINA PECTORIS.—Marie (*Jour. de Méd. et de Chir. Prat.*, February, 1883) reports two cases of angina in hysterical patients. In one the pain commenced in the left little finger, radiating up the forearm and breast of the same side. During the attack, which often lasted some hours, the pulse in the left radial artery became insensible, the lower parts and the entire left side became cold. In the second case the attack was often preceded by general malaise; then suddenly a violent pain supervened in the præcordial region, accompanied by extreme anguish and invincible terror; the pain then radiated toward the neck, the left arm, the little finger, sometimes even toward the leg; the attack lasted ten to twenty minutes, and the face, which was at first tired and cold, became red and warmer. He compares them to the form of angina called vaso-motor by the Germans.

INCOMPLETE TABES.—The symptomatology of locomotor ataxy is sufficiently characteristic to preclude the possibility of mistakes in pronounced cases. Charcot has, however, diagnosed this disease in a number of instances where several prominent symptoms were absent. Such cases may be termed incomplete tabes. The following will serve as examples: 1, A patient with nystagmus, absence of patellar reflex, lightning pains, and double optic atrophy; 2, a man with anesthesia of the face, slight paresis of the orbicularis oris, transitory diplopia, and absence of patellar reflex without lightning pains or inco-ordination; there was also a patch of anesthesia in the area of the radial nerve, and difficulty in retaining his urine; and 3, a man suffering from pains in the right arm, which had lasted nine years, especially severe in the axilla and thumb, with a species of shocks or discharges; also alternations of sensation in the soles of his feet, as if he walked on balls, and when seated, he did not know on what he was sitting. Urination was difficult, and he had no knowledge of the act of defecation. Patellar reflex was present. —*Jour. de Méd. et de Chir. Prat.*, February, 1883.

RUPTURE OF THE PULMONARY ARTERY.—A man, apparently in perfect health, was suddenly attacked with severe pains in the chest, extreme anxiety, and difficulty of respiration, which, after thirty hours, terminated in death (*Medical and Surgical Reporter*). Dr. Arro, who reports the case, found at the autopsy a rent in the pulmonary artery, from which a large amount of blood had escaped into the chest.

ACUTE DIABETES.—Dr. Jones, in the London *Lancet*, February, 1883, describes the case of a police-constable who was admitted into St. Thomas's Hospital in a very

collapsed condition. A careful physical examination failed to discover any reason for the symptoms. No urine was voided for some hours, but a catheter was passed and about four ounces drawn off. The specific gravity was 1040, the reaction acid, and it contained a large quantity of sugar and some albumen. If it had not been for the obtaining of this urine the case might have remained a mystery. The progress of this case was unusually rapid, but still it went through the usual course of such cases. There is only one feature which seems strange, and that is that the disease was only supposed to have lasted five days. Cases have been recorded of death within three weeks of the first recognition of the disease, but never within a few days.

COPPERHEAD VENOM.—Dr. I. Ott (*Virginia Medical Monthly*, February, 1883) comes to the following conclusions: "1. The venom of the copperhead is weaker in toxic activity than that of the rattlesnake. 2. The heart, with both kinds of venom, becomes greatly prostrated, and in rapid deaths is their main cause. 3. The venom of either snake does not affect the sensory nerves. 4. The sensory centres are affected by both venoms. 5. The muscular excitability continues to be little affected at the time of death by the poison of the copperhead. 6. The two venoms greatly resemble each other in physiological activity. 7. The cardiac force, rhythm, and frequency are lowered by both venoms. 8. The arterial tension is greatly lowered by both venoms. 9. The blood, after copperhead-poisoning, shows no microscopic changes of its globules, and no difference in its spectrum."

THE HYPODERMIC USE OF GELSEMIUM.—Drs. Bourneville and Bricon premise some directions as to the hypodermic use of this drug by the following observations: Gelsemium paralyzes the cerebral motor centres. It first increases, then diminishes reflex spinal excitability and cardiac contraction. It also produces a sense of weight in the head, difficulty in the motion of the tongue, trembling of the hands, uncertainty of the fingers, sensations of cold, mydriasis when instilled into the eye, nausea and vomiting. The lethal dose of the alkaloid for man is from nine-twentieths to nine-tenths of a grain. The therapeutical dose of the alkaloid is one-seventh of a grain, and of the tincture seven and a half minims. Eulenburg gives the following formula for hypodermic medication: Gelsemin. chlorhydrate, grs. xv.; aquæ, ʒ vjss. M. S.—℥i. to ij. at each injection. The chlorhydrate of gelsemine is about ten times stronger than the drug itself. The hypodermic use of gelsemine has been attended by good results in neuralgias. One part of gelsemine is soluble in 116 of water. —*Progrès Médical*, March 10, 1883.

SALICYLATES IN DYSMENORRHOEA.—Dr. Chéron says that long ago Weit and Simpson recognized the influence of arthritis on dysmenorrhœa, and that this is very well shown by the results of the salicylate treatment. The salicylates most indicated in dysmenorrhœa are the quinine and the sodium salicylates. The sodium salicylate is employed with advantage in the painful crisis of the onset. At the time of appearance of the pains, two tablespoonfuls of the following mixture suffice: R. Sodium salicylate, ʒ ijss.; rum punch, ʒ j. ʒ vij.; aquæ destill. ʒ iij. ʒ j. If the pain returns some hours later, the same dose should be employed and pushed till six tablespoonfuls at the maximum, in twenty-four hours, have been taken. Quinine salicylate is more particularly indicated in arthritic dysmenorrhœa, where lumbo-abdominal neuralgia is clearly defined, and shows itself some days before menstruation. It is best given in powder. When migraine, or muscular, or articular pains appear before menstruation, sodium salicylate given in 15 to 30 grain doses per diem is indicated. If in the same cases there exists a periodical neuralgia, the administration of two-grain doses of quinine salicylate twice daily often has very astonishing effects. —*Gaillard's Weekly*.

OBSTINATE VOMITING IN PREGNANCY.—Dr. Brock, after discussing the various theories as to the causation of obstinate vomiting in pregnancy (*London Medical Record*, April 15, 1883), arrives at the following conclusions: 1. Obstinate vomiting occurs in multipare where the uterine tissues are lax, and where the os is soft, easily dilatable, and even patent enough to admit the tips of two fingers. This causes him to reject the theory held by Bretonneau and Barnes. 2. Obstinate vomiting is absent in the majority of cases where there is a rigid state of the os, and where one would almost expect it invariably to be present, if the cause were that assigned by Dr. Barnes. 3. Obstinate vomiting is often absent in flexions and distortions of the uterus, and often present where there are no flexions or distortions. This would not be likely if Dr. Graily Hewitt's theory were true. 4. Obstinate vomiting is often absent in inflammatory conditions of the uterus, and present when there are no inflammatory conditions. This ought not to be the case if Dr. Bennett's theory were correct. 5. Because he believes a parallel condition is to be seen in other affections clearly influenced by the individual's neurotic constitution; for instance, obstinate sea-sickness, the occasional vomiting that occurs in pseudocyesis, the proneness to convulsions in certain children whenever ill; or, to take a specific case, the vomiting simulating the obstinate vomiting of pregnancy in a non-pregnant woman in whom the uterus was normal. 6. Because there is no definite line to be drawn between the ordinary cases of sickness in pregnancy and the more severe cases. He has found it associated with intermittent albuminuria. He believes the obstinate vomiting in pregnancy to depend on the idiosyncrasy of the patient.

TRAUMATIC DIABETES INSIPIDUS.—Dr. Statten records (*Centrabl. für die Med. Wiss.*, February 3d) the case of a man who received a wound on the side of his neck and the back of his head. Transitory unconsciousness and double vision occurred, and subsequently deafness on the side of the injury, the left, with total paralysis of the rectus externus on the same, and partial paresis of the same muscle on the opposite side. On the left side hearing was lost in the external meatus, but the ticking of a watch applied to the side of the head was audible. The urine, which amounted to twelve litres daily, was free from albumen and sugar. The treatment, free administration of iodide of potassium, was attended by notable reduction in the quantity of urine. The author supposes the injury to have consisted in destruction of the root of the left abducens nerve, probably with hemorrhagic cyst, and refers to cases in which this pathogeny has been recorded.

THE SIGNIFICANCE OF ATELECTASIS OF THE LUNG.—Tamassia (*Riv. Sper. di Fren. e di Med. Leg.*), from an experimental inquiry, holds that Schroeder's doctrine is devoid of foundation; and if we find by the hydrostatic test and by the other tests which complete it that the lung is absolutely without air, we may with confidence assert that the infant has never breathed.

CANCER OF THE PANCREAS, ACCOMPANIED BY PHLEGMASIA DOLENS.—Dr. L. Cane, in the *British Medical Journal*, reports the case of a clergyman, aged fifty-nine, who consulted him for dyspeptic symptoms, and said his friends had noticed he had not been looking well for some months. A few days after this he complained of pain in the right calf, and there was slight swelling of the leg and tenderness along the inner side of the leg and ankle. Two or three days after the right leg became similarly affected, and it was found that the right saphenous vein was plugged. A careful examination was made to ascertain the cause of the phlegmasia dolens; cancer was suspected, but no evidence of its existence was detected. Three months afterward the patient gradually became aphasic; he could write, but not spell cor-

rectly. A few days after this it was noticed that gradual paralysis of the right arm and right side of the face was coming on. It was not until six months after the patient was first seen that any tumor was detected, but when emaciation had become marked, Dr. Cane detected on the left side a flat, irregular mass, apparently adherent to the spine. The patient rapidly grew weaker, and died unable to make any mental effort, but apparently conscious.

At the *post-mortem* examination it was found that a large irregular mass occupied the place of the pancreas, extending downward about four inches. A number of cancerous glands, joined into one mass, surrounded the aorta and vena cava. The case, says Dr. Cane, illustrates remarkably the statements of Trousseau on phlegmasia alba dolens, that frequently the presence of phlegmasia dolens serves as a valuable aid in diagnosing the existence of deep-seated visceral cancer, in which there is no appreciable tumor.

CARBUNCULUS INTERNUS.—Under this name, Dr. Stanoff describes a case of intestinal anthrax, or Buhl's "mycosis intestinalis," which occurred in a soldier, aged twenty-one, who, soon after eating some boiled pork, began to suffer from vomiting. On admission a few hours later, he presented the following symptoms: extreme prostration, hippocratic face, cyanosis, rapid and weak pulse, cold extremities, moist and coated tongue, thirst, inflation of the belly, tenderness in the epigastric, umbilical, and right iliac regions, labored slow respiration interrupted with sighs and groans, and incessant sickness. There was no diarrhoea, fever, headache, giddiness, or loss of consciousness. The nature of his disease was recognized only after his death, which occurred twenty hours after the first symptoms. About three feet from the cæcum the hyperæmic mucous membrane of the small intestine presented a dark red, roundish, flat, oedematous swelling, two and one-half centimetres in diameter; at its margin was seen a black dense tubercle, about one and one-half centimetre broad. Numerous dark red elevated small spots were scattered along the small intestine. Peyer's patches and the solitary follicles were slightly swollen. The abdominal cavity contained a considerable quantity of a sanguinolent fluid. The spleen and liver were hyperæmic, but not enlarged. The blood was almost black, with easily friable clots. Neither microscopic examination nor inoculation experiments were made. Similar cases of internal anthrax were published by Dr. Rosenberg in the *Moscow Med. Gazeta*, No. 4, 1876, and Dr. R. Albrecht in the *St. Petersburg Med. Wochenschr.*, Nos. 43 and 44, 1878. Of six patients of the latter, five were wool-sorters. In only one of the cases, in which the skin was simultaneously affected, the diagnosis was made during life.—*London Medical Record*, April 15, 1883.

IODIDE OF POTASSIUM IN ENTERIC FEVER.—Dr. Jélenki relates (*Berliner Klin. Wochenschr.*, March 12, 1883) a series of twenty cases in which he has administered iodide of potassium as his chief remedy in the treatment of enteric fever with satisfactory results, prefacing the record of cases with a brief historic notice. A summary of these observations affords the following conclusions: 1. Under the use of the iodide there is a regular duration of from fourteen to sixteen days, which the author observes cannot be claimed for any other means. 2. The temperature and pulse are both slowly and surely lowered, not only for a short time, as with many other antipyretics. 3. A prompt cessation of diarrhoea and abdominal pain. 4. The period of convalescence is shortened by the use of the iodide, and is not attended by the after-effects that often follow other antipyretic agents. The iodide, passing through the whole length of the intestine, affects its glandular structures; and there exerts its antiseptic and antiparasitic properties, so that the author regards it as a specific in the treatment of typhoid fever.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 2, 1883.

PSYCHICAL EVOLUTION AND REGIONAL PHYSIOLOGY.

THE phrenological hypothesis that mind is constituted by an assemblage of distinct faculties whose seats are assigned to separate regions of the cerebral cortex, receives no support from the doctrine of evolution, which is becoming the favorite study of so many students of psychology. "Every form of intelligence," says Herbert Spencer,¹ "being in essence an adjustment of inner to outer relations, it results that as in the advance of this adjustment the outer relations increase in number, in complexity, and heterogeneity by degrees that cannot be marked, there can be no valid demarcations between the successive phases of intelligence. Fundamentally considered, intelligence has neither distinct grades, nor is constituted of faculties that are truly independent. Its highest phenomena are the effects of a complication that has arisen by insensible steps out of the simplest elements." Those to whom this view commends itself—and it is a view based on an exhaustive study of comparative psychology—cannot but regard the pretensions of phrenologists as absurd.

The only division of mind which has stood the test of the ages is the threefold division of intellect, feeling, and volition, and yet these three aspects of mind are, as Bain says, so dependent among themselves, although characteristic in their manifestations, that no one could exist alone; and feeling is the basic substance of Mind.² Intellect, though long divisible into various faculties, as reason, memory, imagination, etc., is fundamentally separable into only three factors, discrimination, or consciousness of difference; similarity, or consciousness of agreement; and retentiveness, or the power of memory, or acquisition. The view, then, expressed in a previous article, respecting the special function of the prefrontal lobes of the cerebrum, compels us to regard these lobes as magazines of cells, which are the living substrata of past experiences, registered here, and serving as the basis of comparison, judgment, and imagination, as well as of volition. The connection of these cells by means of fibres with motor regions and motor cells (the latter are believed to be the large pyramidal cells of the lower strata) is too obvious to require insisting upon here.

"Will and intelligence," says Spinoza, "are one and

the same thing." While this may not be absolutely correct—for we can conceive of intelligence without any element of desire or volition, though practically this is seldom if ever realized—certain it is that intelligence is the essence of volition.

The above being premised, it seems a necessary conclusion that identical parts of the brain are concerned in all the phenomena of mind.³ To use a simple illustration: the complex psychical changes awakened at the sight of an orange are the correlatives of excitation of certain visual centres concerned in the reception of all impressions of a like kind, there is doubtless, too, a calling into action, by diffusion of the excitation, of certain cell groupings in the frontal lobes concerned particularly in the elaboration of impressions, and of such centres (presumably in the occipital lobes) as are concerned in the revivability of gustatory and visceral sensations: the desire and the voluntary impulse which ensue are inseparable parts of the completed perception.

The division of the cerebral hemispheres into lobes is artificial. There is, everywhere, intermingling of nerve-fibres and nerve-cells, and the closest blending by intercellular processes. The arrangement for diffusion of nerve "currents" are of the most perfect kind. Multiple as are the neural manifestations, there is practically, through all, the solidarity of a single unit. The hypothesis of Brown-Séquard and Goltz (advocated also by E. Fournié) that the sensory and motor substrata of function are scattered over wide areas is by virtue of the well-known multiplicity of fibre connections plausible, although it presupposes the occupancy, to a greater or less extent, of a whole cerebral hemisphere by any psychical operation, a supposition hardly compatible with the phenomena of trance or dreaming, where there appears to be concentration of psychical and circulatory energy on a limited portion of the cerebral cortex.

These are strong considerations which favor the views of localization which we have before defended.

In this seeming chaos of cells and fibres there must be orderly arrangement. All analogy leads us to believe this. If the cerebral hemispheres be a representation of inner relations answering to the most stable external relations of the outer cosmos, the order in the inner world must correspond with the order without. The law of physiological distribution of labor must apply to the cerebrum as well as to other parts of the economy. When you move your hand in obedience to a voluntary impulse, such motor excitation comes from a definite region of the cortex. It will always, under similar circumstances, come from the same cortical region. To claim the contrary introduces the element of disorder into the scene, which all experience and all analogy forbid. The fibres of the corona radiata which carry visual impressions to the cortex must pursue a definite route. Other sense impressions must follow, as it were, a beaten track to some region of the gray matter near the surface where they are for a time concentrated, to be afterward, it may be, widely diffused and blended with fibres of different sensory nature and motor fibres. That the visual, auditory, and tactile centres occupy a wide area of the cortex

¹ Primitive Psychology, vol. i., p. 388. Cited by Bastian.

² Bain: Mind and Body, pp. 44-83. Herbert Spencer: Primitive Psychology, vol. i., part 3, chap. viii.

³ See Rebot, Diseases of Memory, for striking illustrations. The nervous process is the same in feeling, perception, and remembrance. Reawakened feelings occupy the same parts as the original feelings.

seems probable, when we consider the part which they have in building up the fabric of our mental experiences.

These opinions are in harmony with those expressed by H. Charlton Bastian ("The Brain an Organ of Mind"), Broadbeut ("Cerebral Mechanism of Speech and Thought"), Croom Robertson (review of Ferrier in *Mind*, 1877). Bastian, who charily and reservedly admits the doctrine of localizations as applied to topographically distinct foci of sensation, while admitting the essential facts of motor localizations, was the first formally to propound the theory of "Perceptive Centres" in the cortex (*vide Journal of Mental Science*, 1869), also to state the view, supported of late by Exner, "that there may be much and compound overlapping of areas, and though the area pertaining to the impressions of any particular sense in the cerebral hemispheres may be a very extended one (not to speak of the still further complication brought about by the communication established between the nerve-cells of the sense area with those of others in the same hemisphere and the opposite hemisphere), still it may well be that certain portions of the surface of the cerebral hemispheres might correspond more especially to the *maximum* amount of nerve-cells and fibres pertaining to some one or other of the various senses."

With regard to Exner's investigations, we called attention to them about a year ago (*vide MEDICAL RECORD*, April 15, 1882), and need not repeat what we said then. Exner's observations strikingly confirm the somewhat hypothetical conclusions of Bastian and Croom Robertson, to which allusion has just been made. According to Exner, the cortical centres are rather areas of functional concentration than sharply demarcated sensory and motor foci, and the diffusion and interblending of fibres which there occur, and the overlapping of one district by another, afford a plausible explanation of the different results which have been noted in lesions of these districts, also of the recovery from functional paralysis, which in animals so often follows such lesions. In other words, they are "vicariating areas."

The cortical field of vision, according to Exner, corresponds more exactly with the region assigned to this sense by Muhr and Munk than to that assigned to it by Ferrier, viz.: the angular gyrus. This "perceptive centre" has a relatively wide area in the upper and middle occipital lobes, extending thence into the cuneus. Here again Bastian's prevision is justified. According to Exner's observations, the tactile fields correspond very closely with the motor fields for the same body regions, and this is in striking confirmation of the studies of Betz and Luys on the functional significance of the cells in the stratified zones. "As regards the physiological significance of certain zones," says Luys,¹ "and the relation of each to the phenomena of sensation and motion, we may by the laws of analogy believe that the submeningeal region, principally occupied by the small cells, may be specially connected with the phenomena of sensation, while the deeper regions occupied by groups of large cells may be considered as the most important regions that give rise to motor phenomena."

In studying this question, Luys bases his conclusions principally on data acquired from a study of the spinal cord, which show that those regions (the posterior horns) where small cells occur, have sensory functions, while the regions of large cells, the anterior cornua, are motor. Betz's special contribution to this micrographical study is that the large, so called motor-cells (triangular cells of Luys, pyramidal or giant-cells of Meynert), predominate in the neighborhood of the fissure of Rolando,¹ where Ferrier's motor-centres abound. (And just here there is a striking correspondence between Ferrier's and Exner's localizations as applied to both hemispheres.)

Exner's "absolute" and "relative" areas correspond to regions of greater or less concentration and diffusion of fibres. There is, for instance, an absolute cortical field for the right upper extremity in the upper parietal lobule, the upper two-thirds of each of the central gyri, and the paracentral lobule of the left side. The absolute motor field for the left upper extremity occupies corresponding regions in the right hemisphere, but of considerably more limited extent. The relative fields for these extremities "shade off on both sides with diminished intensity from the absolute areas."

Exner's absolute field for the lower limbs is nearly the same as for the upper, and he explains the phenomena of separate paralyses of the arm and leg by stating "that the areas for the arm are more sensitive than for the leg."

Exner's views, as to localization, will, if proved to be sound (and future investigations are needed to confirm or disprove them), cause physiologists somewhat to modify the current theories of localization, based largely on the carefully conducted experiments of Ferrier. Thus, while teaching that there is no absolute speech centre he locates his relative speech centre just where Broca in 1861 located it, and where Ferrier locates it, *i.e.*, in the posterior part of the third frontal convolution. This being only a "relative" centre, it will not be surprising if cases should now and then happen where injury should occur to this area without aphasia.

Exner's conclusions are based on one hundred and sixty-nine positive observations, but as we said in a former article, in which the work of this physiologist is reviewed, "it must be remembered that there are a good many possibilities of error in Exner's methods, since he used cases of cerebral tumor to work up. Some of his conclusions must, therefore, be accepted with considerable caution."

THE HYPODERMIC USE OF THE CYANIDES.

THE number of substances with which cyanogen is compounded has now become very considerable, largely through the fondness of the French for this particular poison. The United States Dispensatory gives a list which includes the cyanides of ethyl, of gold, mercury, silver, zinc, and potassium. These have all been more or less used. Somewhat over a year ago Dr. Galezowski, of Paris, made a communication to the Société de Biologie upon the subject of the hypodermic use of cyanide of mercury in the treatment of syphilitic affections of the eye, especially in choroiditis, iritis, optic neuritis, and atrophy of the optic nerve. He then claimed that cases

¹The Brain and Its Functions, page 24. D. Appleton & Co. These views were first propounded by Luys in his *Recherches sur le Syst. Nerveux Cerebro-Spinal*, p. 163. 1865.

¹P. Betz in *Centralblatt.*, 37 and 38. 1874.

which had not been relieved by mercury given in the ordinary way, were sensibly improved by the cyanide.

Dr. Galezowski has recently made a further communication upon the subject. The cyanide of mercury, he states, could only be employed in very small doses (five to ten milligrammes). Wishing to give the cyanogen in larger amounts, he prepared, with the advice of M. Frémy, solutions of cyanide of gold and potassium, of silver and potassium, and of platinum and sodium. These he found he could give in doses of twenty to thirty milligrammes without trouble. Three cases are reported in which the optic atrophy of *tabes dorsalis* was checked in its progress under the use of these preparations. Dr. Galezowski is inclined to believe that in these cyanides we have a remedy which is specially helpful in checking the progress of atrophy of the optic nerve in syphilitic and tabetic affections. Sometimes the cyanide of mercury and sometimes that of other metals acts best.

A TWO-YEAR COURSE PREPARATORY TO THE STUDY OF MEDICINE.

OUR attention has been called to the preparatory course for medical students offered by Cornell University. Students are urged to take a full four years' course in arts or in science. Should this not be possible, however, the two years' course, which embraces branches calculated to help in the future study of medicine, is recommended. This course includes French and German, chemistry, zoology, physics, anatomy, physiology, and hygiene. A considerable amount of laboratory work is also required.

We are told that a certificate of attendance is given, which usually exempts the student from one of the three years of study commonly required for graduation in medicine. If this is so, we have certainly failed to observe any acknowledgment of the fact in the printed announcements of our medical colleges. Those desiring a genuinely higher education will be inclined to doubt whether a couple of courses of medical lectures are enough to make a good doctor, even of one who has been through a preparatory course. However, as medical education stands now, a two years' preparatory course, with two years of actual medical study, are much better than the nominal three years of study which the majority of American medical students pass through. We can commend preparatory courses, therefore, provisionally, as helpful. But while they assist in giving a technical education, it should be borne in mind that they do not educate the student in the broadest and best sense of the term. The more ambitious, therefore, will not be content with merely preparatory courses.

We should not omit to state that Yale, and, we believe, other colleges have organized these preparatory courses, some of which extend over a longer time than two years.

ALCOHOLIC INEBRIETY.

THAT industrious and esteemed writer, Dr. T. D. Crothers, who may truly be said to be inebriated with inebriety, has made the various aspects of his chosen specialty familiar to the readers of medical periodicals. We have learned that inebriety is a disease, and that he is a bad, bold man who will uphold the contrary: we have been

told that inebriety has a hundred thousand victims in this country, that it is daily increasing, that its pathology, though mysterious, is distinct; that its various phenomena are woven into the social fabric, and affect all classes, all interests, and all phases of life; in fact, that inebriety is a pathological entity of the profoundest significance, scientifically, medically, and socially.

It may well be thought that this is taking a rather large view of the matter; and yet it is quite possible that the medical profession may in time be brought over to it. A particularly strong reason for this is the constant increase in medical literature of scientific, in distinction from sentimental, contributions to inebriety. There has recently appeared a work by Dr. Joseph Parrish, a pioneer in this field, upon the subject of alcoholic inebriety.¹ It is not an elaborate treatise, but it discusses the question in a scientific manner, yet with candor and caution. The point which it suggests most strongly, is that the subject of temperance and intemperance is at present looked at almost entirely from the sentimental side, and that those who are most enthusiastically interested in lessening drunkenness and inebriety, study the moral side only, or chiefly. There can be no doubt that this is a serious mistake, and that much help could be gotten if only sociologists and medical men would unite to study the problems of intemperance and inebriety philosophically. The question whether inebriety is a disease or a vice, need cause no trouble practically, since it is only a matter of words. A vicious habit (like any habit), by repetition establishes in time a definite change in nutrition, and, perhaps, structure. We may call this change disease, or a vicious habit with an unknown somatic basis, as we choose. It is a definite thing at all events, and one to be treated by other than mental therapeutics alone. This is, we believe, the gospel which our modern apostles of the inebriate pathology are proclaiming.

THE INCREASE OF PHYSICIANS IN NEW YORK CITY.

IN the list of registered physicians in the County of New York, published by Caswell & Hazard, January 1, 1881, the total number given was about twenty-four hundred. In a recently published revised list, the record is brought down to January 1, 1883. The number now is over 2,800, showing an increase of about four hundred doctors in two years. During this time the estimated increase of population has been from 1,230,000, on January 1, 1881, to 1,295,000 on January 1, 1883, or about 65,000. In other words there has been a new doctor for every 162 new inhabitants. This does not take into account all the deaths and removals, which in the two years amount probably to over eighty. Still, even allowing for this, it shows how densely New York City is becoming crowded with physicians, and that medical men are coming in much faster proportionately than the rest of the population.

In 1881 the ratio of doctors to the population was one to 514; now it is one to 463. The above figures relate to registered or legal practitioners. Of the 2,800 now in the city, about 1,800 are entitled to be termed regular by virtue of their names appearing in the Medical Regis-

¹ Alcoholic Inebriety, from a Medical Standpoint, with Cases from Clinical Records. By Joseph Parrish, M.D. Philadelphia: J.P. Blakiston & Co. 1883.

ter. There are, therefore, a thousand irregulars among us. Here truly are conditions which require a struggle for existence, and the young man intending to practise medicine may well hesitate before starting out in New York.

THE PREVALENCE OF SMALL-POX.

VARIOUS telegraphic reports seem to indicate a somewhat extensive prevalence of small-pox at present in the United States. During the month of April there was a mortality from this disease of over one hundred and sixty cases, more than half of which occurred in New Orleans. During the last week of April the mortality was sixty-four cases, showing that the disease was increasing. In the month of May a number of new foci appeared. It is reported that West Virginia has been particularly afflicted with the scourge. On May 26th it was also announced that twenty-six cases of small-pox had occurred in St. Michaels, Minn. Small-pox broke out last month in the County Prison at Lancaster, Pa. Much consternation has been excited in Cincinnati, O., by the sudden appearance of small-pox in an institution for teaching music in that city. In this latter case the disease is said to have been spread through the failure of the attending physicians to diagnose the disease. A number of cases has been reported in St. Louis, Philadelphia, and Nashville. A few cases developed in this city during the month of May.

On the whole, it seems that health authorities ought to be specially vigilant in watching for and guarding against this much dreaded disease.

THE ORIGIN OF THE AMERICAN MEDICAL ASSOCIATION.

IN the light of the great amount of silly talk regarding the "rebellion," "secession," etc., of the New York State Medical Society, it is interesting to read the account of the origin of the national organization as given by Dr. Toner, of Washington.

"The first meeting (of the American Medical Association) was held in the city of New York, May 5, 1846, on a call of the *Medical Society of the State of New York* for a National Medical Convention." This action was brought about chiefly through the activity of a (at that time) New York physician, Dr. N. S. Davis.

It is a historical fact, therefore, that the New York State Medical Society called the American Medical Association into existence.

The child repudiates the parent before the latter has reached the maturity of a chartered existence.

THE MEDICAL ASSOCIATION OF GEORGIA

Held its third annual session at Athens, April 18 and 19, 1883. The annual address was delivered by the President, Dr. K. P. Moore. The following officers were elected: *President*—Dr. A. W. Calhoun, of Atlanta; *Vice-Presidents*—Drs. R. J. Nunn, of Savannah, and M. P. Deadwiler, of Elberton; *Secretary*—Dr. Jas. A. Gray, of Atlanta; *Treasurer*—Dr. E. C. Goodrich. The Society adjourned to meet at Macon, the third Wednesday of April, 1884.

News of the Week.

THE EVOLUTION OF THE NEW CODE.—The fourth article by Dr. Piffard on "The Status of the Medical Profession in the State of New York," published in the *New York Medical Journal* of May 26th, gives an interesting history of the present State Code, and explains the reasons which led the committee to adopt the present non-restrictive clause. The subject is admirably presented, and the article reflects much credit on its author. It should be read by all who candidly desire to know the whole truth regarding New York State's ethical position.

The Independent Practitioner is to become a purely dental journal, and will be edited by Dr. W. C. Barrett, of Buffalo, N. Y. We trust it will continue successful.

THE MASSACHUSETTS STATE MEDICAL SOCIETY holds its one hundred and second annual meeting at Boston, June 12th and 13th.

PRESIDENT GILMAN, of the Johns Hopkins University, will, says the *Maryland Medical Journal*, sail for Europe shortly in order to study the methods of medical education in vogue there, with a view to utilizing the experience thus gained in the organization and conduct of the medical school to be established in connection with his own university.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.—At the stated meeting, held May 28th, notice was given of the following proposed amendment to the by-laws:

"No member of this Society shall assume any sectarian designation indicating that his practice is based on any special doctrine, or dogma, or specified method of treatment."

The following amendments were unanimously adopted: 1. "The members of this Society shall be governed by the Code of Ethics, adopted by the Medical Society of the State of New York, February 6, 1882." 2. "No person shall be eligible for membership in this Society who is a member of a county society not entitled to representation in the Medical Society of the State of New York."

THE EPIDEMIC FUND of one hundred thousand dollars, to be used in the discretion of the President of the United States, will be employed only in case of actual or threatened epidemic, in which event the Secretary of the Treasury is empowered by the President to disburse the fund in aid of State and local boards of health to prevent the introduction or spread of the disease.

FEMALE PHYSICIANS FOR THE NATIVES OF INDIA.—Much success has attended the subscription now being raised in Bombay to secure the services of female physicians for the native women. Miss H. Johnson, the Directress of the Medical Mission at Agra, one of the largest cities of Northern India, gives a deplorable picture of the ravages of sickness and debility among the native women, whom no male physician is allowed to approach, and who, living in ill-kept rooms, and often sitting, or even sleeping, on the bare floor, are at the mercy of every epidemic. Even when European medicines and prescriptions are within reach, they are often rendered useless by the opposition of jealous and super-

stitutional relatives. There can be no doubt that the establishment in every great Hindoo city of a native hospital, officered by competent female doctors, would save many lives every year.

DR. HOLMES NOT GOING TO ENGLAND.—Dr. Holmes has been invited to Birmingham, and the promise has been made him that if he will go a reception by the members of the medical profession will await him there. He was thus invited on the supposition that he was about to visit England, but this rumor proves to have been an error. His letter declining the Birmingham honor is made public in a London newspaper, and is as follows, the date of it being April 21, 1883: "I am very sorry to say that the story of my intended visit to England is a pure invention. I should find a great deal to enjoy, I am sure, in 'our old home,' but I hardly expect to see it again, being myself a poor traveller, and having learned by troublesome experience that I am safest when I let my children do the travelling for me. I thank you most cordially for your very kind invitation to visit Birmingham. It is a source of great pleasure to me to feel that I have many good friends in England—friends on whose faces I have never looked, and probably never shall, but whose warm heart-beats reach me through the oldest of telephones—the one that 'wafts a sigh from Indus to the pole.'"

THOSE TOLEDO SCHOOLS is the title of an editorial in the *Columbus Medical Journal*, in which the inner history of the development of medical education at Toledo is given. We are told that there are now two medical colleges in that city. It seems that there was a school started in 1878, that soon after the "outs" got a charter and started a regular college. Now the original "school" has a charter also. The *Columbus Medical Journal* says: "Six months ago, the stand taken by the Illinois Board of Health would probably have prevented the birth of either school; but its recent pusillanimity has made it the laughing stock of the country, and utterly destroyed its usefulness." It seems a little unfair to lay it all on the Health Board of another State.

A BUST OF DR. J. M. TONER, of Washington, is to be made by Mr. J. Q. A. Ward for the Congressional Library, in honor of the gift from him of a large and valuable collection of medical books.

MEDICAL ASSOCIATION OF CENTRAL NEW YORK.—The sixteenth annual meeting of the Medical Association of Central New York was recently held at Syracuse, N. Y. The meeting was quite well attended and was an unusually interesting one. Dr. C. Mercer showed specimens of bacillus tuberculosis.

AN ANATOMY ACT designed to prevent body-snatching by providing for a suitable supply of "material" for the colleges, has been passed by the Quebec Parliament.

A WOMAN ON THE HOSPITAL STAFF OF A GENERAL HOSPITAL.—At the recent examination for the house staff at Mount Sinai Hospital, Dr. Josephine Walter was a successful candidate, and has received the appointment. Miss Walter is a graduate of the Woman's Medical College of the New York Infirmary, and after receiving her diploma spent six months in further studies before venturing her examination.

WOMAN'S MEDICAL COLLEGE OF PHILADELPHIA.—Dr. W. W. Keen has been elected to the chair of surgery in the Woman's Medical College of Pennsylvania.

PROFESSOR RICHET was elected a member of the Academy of Sciences, at its last meeting, in the section of Surgery and in the room of Dr. Sédillot, deceased. The struggle was hard between the newly elected Academician and the venerable Jules Guérin, but notwithstanding the greater claims of the latter, the result that took place was anticipated.

A SANITARY ARMOR.—The National Health Society, London, has introduced a form of garment, made of mackintosh, to be worn by those people who are compelled to enter the apartments of persons suffering from contagious diseases. Used in conjunction with a medicated cotton respirator, it is said to be a protection against contagion.

HAVANA AS A SOURCE OF YELLOW FEVER INFECTION.—Twenty-two deaths from yellow fever occurred in Havana during the week ending May 26th. The act of Congress for the prevention of contagious diseases, which requires the sanitary inspection of vessels at Havana bound for the United States, expires on June 2d, and Congress has made no provision for a renewal of the act. The want of sanitary inspection and information in bills of health will prove, it is feared, injurious to vessels and a danger to ports in the United States. It is stated that the President has authority to act in the matter. The usefulness of a competent, responsible inspector, serving as heretofore in the American consulate, is apparent. Havana, with its yellow fever, is constantly endangering the ports of the United States.

A SUCCESSFUL SURGEON PAINTER.—Sir Henry Thomson's picture at the exhibition of the Royal Academy is hung on the line.

THERE IS AN EPIDEMIC OF SCARLET FEVER at present in the town of Flatbush, L. I. There are now forty cases being treated. Two cases have terminated fatally.

THE EPIDEMIC FUND OF THE TREASURY DEPARTMENT.—The Secretary of the Treasury has written a letter to the Surgeon-General of the Marine Hospital Service, of which the following is a copy: "The President has directed the Secretary of the Treasury to take charge of the expenditure of the appropriation in the Sundry Civil Service Appropriation act of March 3, 1883, for the prevention of the spread of epidemic diseases. This department has determined to commit to the Surgeon-General of the Marine Hospital Service the inquiry into the need of the use of the money and the duty of applying it in cases that arise thereupon, and you are hereby authorized to make requisition from time to time for such sums as may be deemed necessary to carry into effect the purpose of said appropriation, to be expended in accordance with the existing regulations of the Marine Hospital Service."

HUDSON COUNTY (N. J.) MEDICAL SOCIETY.—At the annual meeting the following officers were elected: Gordon R. Dickson, M.D., President; W. P. Watson, M.D., Vice-President; J. A. Exton, M.D., Secretary; C. F. Kyte, M.D., Treasurer.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 9, 1883.

R. E. VAN GIESON, M.D., VICE-PRESIDENT, IN THE CHAIR.

DR. WACKERHAGEN presented specimens in behalf of a candidate.

DR. FERGUSON presented a specimen, illustrating
PERICARDITIS,

occurring in a female patient, aged fifty-four, a native of Ireland, and a dressmaker by occupation. She was admitted into the New York Hospital on September 11, 1882, with the following history: Three years previous to date she was in a hospital for kidney disease, where she improved under treatment. Up to three weeks previous to her admission she was fairly well and attending to business. At that time her feet began to swell, and her dyspnoea, which has been moderate since her first illness, became worse, and on admission she was suffering from cardiac palpitation. There were no visual or cerebral symptoms.

While in the hospital her temperature was subnormal (97.7° F.), her respiration ranged from 18 to 34 per minute, and her pulse from 98 to 158. She was stimulated by whiskey and digitalis, and was cupped over the region of the kidneys.

Physical examination revealed double hydrothorax, and a loud blowing bruit over the base of the heart, on both sides of the sternum. During the last three days of her illness she passed only a few ounces of urine, which contained a large percentage of albumen. All her symptoms became aggravated, and she died (comatose for several hours previously) on September 15th, three days after admission.

Autopsy, twenty-two hours after death.—There were 500 c.c. [17 ounces] of serum in the right pleural cavity. The lungs were congested and oedematous. The heart was very large, and both layers of the pericardium were covered by recent lymph. The ventricular walls, especially the left, were hypertrophied; the left ventricle was dilated, the valves were competent, and the endocardium was slightly thickened.

The kidneys were far advanced in chronic diffuse nephritis. They were much smaller than normal, and there was a great deal of fat in the convoluted tubes and many casts in the straight tubules.

The liver was pigmented, the central vessels were dilated, and there was atrophy of the liver-cells in their neighborhood. There was excess of fat in the liver, also in the muscular fibres of the heart.

Dr. Ferguson also presented a specimen illustrating

PERICARDITIS—THROMBUS OF THE ARCH OF THE AORTA,

from a male, aged seventy. He was found on the street in an unconscious condition, and pulseless at the wrist. He was aroused, and, by the assistance of two men, walked into the ambulance. He was unconscious all the time he was in the hospital, and pulseless at the wrists. He died thirty-six hours after admission.

Autopsy, twenty-four hours after death.—The upper lobe of the right lung was in the condition of gray hepatization. The lower and middle lobes were intensely congested and oedematous. The left lung was congested and oedematous throughout. The bronchial tubes, on both sides, contained mucus and pus. The pericardium contained two ounces of purulent fluid. Both layers of the pericardium were covered by recent lymph. The left ventricular wall was much hypertrophied, and the cavity of the left ventricle was small. The valves were competent. There were several small patches of atheroma in the segments of the aortic and mitral valves. The thoracic aorta was moderately dilated.

There was a clot arising from the arch of the aorta, between the origin of the subclavian artery on the left side, and the common origin of the innominate and left common carotid, one inch in length, and one-half inch in breadth, and the same in thickness, with its centre broken down. It was not organized; a part of it passed up into the left common carotid. Brain. The left middle cerebral artery was occluded by an embolus, which filled the artery and some of its branches, and the regions of the brain supplied by these branches were softened. The kidneys were atrophied, and in the condition of chronic diffuse nephritis. The urethra. There were two strictures of the urethra, each of which admitted a sound one-eighth of an inch in diameter. One was situated in the pendulous portion, two inches from the meatus, the other at the bulbo-membranous junction.

These cases resembled each other in that both patients were advanced in years; both had chronic diffuse nephritis, hypertrophy of the heart, thickening of the endocardium, and pericarditis.

The Society then went into executive session.

THE SECOND GERMAN CONGRESS OF INTERNAL MEDICINE.

Held at Wiesbaden, April 18, 19, 20, and 21, 1883.

PROFESSOR FRERICHS, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

(Concluded from p. 551.)

DISCUSSION ON DIPHTHERIA.

PROFESSOR KLEBS followed with a paper in which he agreed in the main with the preceding speaker, and thought there were undoubtedly different forms of diphtheria depending upon different micro-organisms. In Prague he had seen a form of malignant diphtheria in which there were hemorrhagic exudations in the central nervous organs, with severe general symptoms, while the local throat affection was confined to a spot the size of a penny. The superficial layer of this membrane was composed of masses of straight or bent threads mixed with epithelial debris. Beneath this was the ordinary fibrinous exudation, in which were numerous round masses of very small micrococci closely packed together. In Zurich he had found another form prevailing, in which the affection was more local. There was no enlargement of the spleen, and slight or no changes were to be found in the kidney. Death occurred through invasion of the respiratory tract by the false membrane, or from pulmonary inflammation. Paralysis seemed to follow this variety less frequently than it did that which he had met with in Prague. In this form the micro-organisms were bacilli, while in the less localized variety first mentioned they were micrococci. He considered it important to thus distinguish between these two varieties of diphtheria, as in this way we might be able to remove many of the difficulties of prognosis, and, furthermore, obtain data upon which to formulate the therapeutical indications. He had had but little experience with scarlatinal diphtheria, but believed it to be a distinct variety of the disease. He had always found a swelling of the submaxillary glands in such cases, and had discovered that they were infiltrated with micrococci.

DR. HEUBNER, of Leipzig, questioned whether the local inflammatory process might not depend upon a temporary interruption of the blood-supply to the part. He had experimented upon rabbits by closing temporarily the vessels supplying the base of the bladder, the circulation being restored again after the lapse of a short time. At the end of twenty-four hours there was a hemorrhagic oedema of the mucous membrane; an exudation appeared on the second day; and on the third day a perfect picture of commencing diphtheria was presented. A further

experiment seemed to him to explain the onset of infectious symptoms. After the mucous membrane had become diphtheritic, he injected anthrax poison into the substance of the dorsal muscles. When this was done early, the poison was found chiefly in the locally diseased parts. The speaker concluded, therefore, that the contagium of diphtheria was not the cause of the exudation, but was deposited in it through the simultaneous occurrence of a local inflammation with a general infection.

In accordance with these views, he placed little reliance upon local treatment, but endeavored to overcome the diphtheritic poison by remedies internally administered.

DR. JÜRGENSEN, of Tübingen, was inclined to regard croup as a disease distinct from diphtheria, and related a case in support of his view. As to treatment, he thought it best to remove the membrane, as far as possible, for the sake of cleanliness, but opposed the employment of harsh or irritating substances to effect this object. He considered a general disinfection of the entire body as impossible.

DR. ROSSEACH, of Jena, looked upon the tonsils as the portals through which the diphtheritic poison found entrance to the system, and on this account advocated their removal as a prophylactic measure. When they were large he cut them away; in other cases he destroyed them with the galvano-cautery.

The discussion was prolonged to the close of the session, a number of gentlemen taking part therein. In general, it was agreed that the affection designated diphtheria was not a single disease, but that there were two or more conditions at present confounded under this one name.

At the opening of the third session DR. BINZ, of Bonn, presented a paper upon

THE ABORTIVE TREATMENT OF INFECTIOUS DISEASES.

Two causes were at work which tended to make infectious diseases less dreaded now than they were in former ages. These were an improved hygiene and an improved therapeutics. Hygiene alone will not suffice to prevent entirely the occurrence of epidemics, for the simple reason that it can never become perfect; and as long as a single focus exists favorable to the growth and development of the matter of contagion, there is danger of its spread to other localities. Hygiene and therapeutics must go hand in hand. But though we can never hope to prevent absolutely the occurrence of any infectious disease, the author believed that the time would come when we could strangle the disease at its inception and thus rob it of most of its terrors. We have already five remedies which we can send after certain exciters of disease to paralyze them and abort the diseases to which they give rise. These remedies are quinine, mercury, iodine, arsenic, and salicylic acid. The antagonism of quinine to the malarial poison was dwelt upon; the explanation of its action being that it was a poison to the micro-organism found in this disease. This was not mere conjecture, but had been proven by direct experiment. Although at present there were no remedies to be regarded as specific antidotes to the microscopical organisms found in tuberculosis and diphtheria, Dr. Binz believed that they would some time surely be found. These diseases were now in the same condition as were rheumatism and malarial fevers before the discovery of the antidotal effects of salicylic acid and quinine. In concluding, the speaker predicted a glorious future for therapeutics.

DR. ROSSEACH, of Jena, followed with a thoughtful article upon the same subject, agreeing with Dr. Binz in his hopes of vanquishing these enemies of mankind. He advocated the establishment of a special commission to study the action of the various drugs now in our possession, and of others yet to be discovered, to determine their proper dose and to ascertain their poisonous effects upon the lower as well as the higher organisms. In case of an epidemic occurring in any locality this commission

should recommend some particular remedy, whose action was supposed to be inimical to the disease in question. This remedy was then to be used by all physicians in their treatment of the disease, and a report could be made to the central body, upon the subsidence of the epidemic, of the results obtained by the various observers. In this way we might hope to make rapid advances in our search for specific therapeutical agents.

The discussion which followed was without special interest. The speakers agreed upon the desirability of the establishment of some such commission, which could formulate some general plan of investigation, and collate the results obtained by individual workers.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

The Fifth Annual Congress, held in New York, May 21, 22, and 23, 1883.

(Continued from p. 580.)

SECOND DAY—AFTERNOON SESSION.

DR. LOUIS ELSBERG, of New York, read a paper entitled,

REFLEX PHENOMENA DUE TO NASAL DISEASE.

More than twenty years ago he introduced the subject that naso-pharyngeal disease, especially with considerable thickening and congestion of the mucous membrane, was liable to be attended with loss of memory and mental depression and other nervous phenomena. In 1863 a remarkable case of chorea came under his observation, so severe that the movements continued even during sleep. The nervous affection seemed to depend upon nasal disease, so much so that he directed his attention exclusively to this difficulty, and *pari passu* with the cure of the disease of the nose the chorea was completely and permanently relieved. The affections to which his attention had been especially directed were melancholia, chorea, reflex epilepsy, neuralgia, especially of the supra-orbital nerve, gastric disturbances, especially diseased conditions of the upper part of the digestive tract, uterine disorders, affections of the genito-urinary membrane, disorders of smell and taste, also of hearing and sight, and numerous affections of the naso-respiratory tract, especially various alterations in the speaking and singing voice, laryngeal cough, bronchial asthma, etc. In explanation of the intimate connection which seemed to exist between nasal disease and affections of the nervous system, the author of the paper referred to a communication made by Dr. A. Jacobi to the New York Obstetrical Society, in which three points were made: First, the trigeminus, with all its branches, is subject to direct or reflex irritation from the inflamed nasal mucous membrane; second, that thickening of the mucous membrane, or narrowing of the nasal passages in the child, especially such as attend the presence of a polypus, seriously interferes with respiration, and the result is an accumulation of carbonic acid gas in the brain, which affects the respiratory centre of the medulla oblongata; third, the nasal mucous membrane and the dura mater have an intimate relation with each other, so much so that each can be injected from the other side.

DR. J. N. MACKENZIE, of Baltimore, drew especial attention to the great frequency of cough as a symptom of nasal disease. He had reached this conclusion with reference to this symptom by experiment, as well as from clinical observation. From an extended study of the subject, both clinically and experimentally, he had reached the following conclusions, already presented in a paper which he had read before one of the medical societies in Baltimore: First, clinical experience and experimental observation had shown that in the nose, as well as in the pharynx, there exists a definite and well-defined circumscribed area, the irritation of which, caused by either pathological process or artificial means, is capable of

producing a series of reflected phenomena, but especially cough; second, this reflex area corresponds, in all probability, to that portion of the mucous membrane which covers the posterior part of the corpus cavernosa; third, this reflex is only produced when *this* area is stimulated; fourth, all parts of this sensitive area are not equally sensitive to irritation, the most sensitive being the posterior end of the inferior turbinated bone and the erectile body on the septum immediately opposite; fifth, the susceptibility to reflex cough varies greatly in different patients. The reasons which he gave for thus localizing the sensitive area, were: First, the reflex cough may be produced at will by artificial stimulation of this area; second, the reflex cough may be dissipated by topical applications to this sensitive surface; third, in all cases of nasal polypi in which asthmatic attacks are present they are only produced when the polypi are situated in the posterior part where they impinge upon the sensitive area; fifth, foreign bodies lodged in this area will give rise to reflex cough, but when lodged in the non-sensitive portion of the nose they do not produce such reflex phenomena.

DR. J. O. ROE, of Rochester, made special reference to asthma, especially that which occurs in acute attacks, such as is seen with hay fever, as being produced by disease of the nose, particularly posterior hypertrophy of the mucous membrane. He thought that in nearly all cases of hay fever it would be found that disease of the nose was an essential cause. He related the history of one case in which remarkably favorable results followed removal of hypertrophied turbinated tissue.

DR. C. SEILER, of Philadelphia, referred to cases in which choric symptoms were present, due to nasal irritation, and in which the nervous manifestations disappeared with the cure of the nasal disease. He also referred to cases of extremely violent coryza, lasting but for a short time, developing very suddenly, and attended by a profuse watery discharge, which he thought might perhaps be included under the class of cases referred to by Dr. Elsberg. He recited the history of one remarkable case; but there was no evidence of hypertrophy of the nasal mucous membrane.

DR. F. H. BOSWORTH, of New York, thought it not well to call the cases to which Dr. Seiler had referred cases of coryza, for he had examined the fluid discharged both microscopically and chemically, and found it composed almost entirely of pure water. They were first described by Sir Benjamin Brodie, subsequently by Sir James Paget, and afterward by writers in the *London Lancet*, making in all six cases, which covered the literature of the subject. He believed that they depended entirely upon some neurotic condition of the general system, but were not reflex in character. Dr. Bosworth also directed attention to the occurrence of spasm of the glottis dependent upon atrophic rhinitis, which he thought was, quite probably, reflex in character. The youngest patient in whom he had seen this symptom was six years of age, and the oldest, a man fifty-five years of age. Simple applications, such as a weak solution of salt, keeping the nasal mucous membrane moist, relieved completely the tendency to the attacks of spasm. One point with regard to Dr. Jacobi's explanation, mentioned by Dr. Elsberg, and that was, Dr. Bosworth did not believe that chronic thickening of the nasal mucous membrane or nasal polypi occurred in children. The condition which was seen was glandular tissue, and not mucous membrane which has become thickened.

DR. W. C. JARVIS, of New York, referred to a case in which relief from asthmatic attacks followed removal of a posterior gelatinous polypus and opening up of one nostril in a case in which both nostrils had been obstructed by reason of a polypus and also a deviated septum.

DR. ELSBERG, in closing the discussion, said that he was not aware of Dr. Mackenzie's interesting contributions to our knowledge of the sensitive points about the

nose, and had been much interested in the conclusions reached. He did not regard the case of excessive watery discharge, referred to by Dr. Seiler, as one which belonged to the category included in his paper. The cases of spasms of the glottis he had alluded to, and was pleased to learn that Dr. Bosworth had observed so many similar cases.

DR. CLINTON WAGNER, of New York, then read a paper entitled

SMELL HYGIENICALLY AND MEDICO-LEGALLY CONSIDERED.

The author of the paper defined odors as impalpable bodies in the form of vapor, and that the function of the special sense of smell was to be able to recognize and distinguish the impression of odors, one from the other, on the terminal filaments of the olfactory nerve. Dr. Wagner then directed attention to the great variety of smells with which the human nose became cognizant, and spoke of the exposure of workmen to certain noxious vapors and apparently without deleterious results. He explained this fact on the ground that all these workmen were engaged in active occupations, and therefore that the influence of the poison was not felt; whereas when the same noxious odors, disagreeable smells, were experienced by the feeble or delicate, who led a less active life, the influence produced was physically detrimental. The medico-legal aspect of the question was presented in the detriment to health and to comfort embraced under the legal definition of a nuisance, which might be experienced by those who lived in the immediate locality of bone-boiling establishments, petroleum yards, abattoirs, etc.

DR. BEVERLEY ROBINSON, of New York, in discussing the paper, directed attention to the distinction which should be made between deodorizers and disinfectants, and while he did not wish to say that it was not valuable to be able to detect odors, yet he believed that the use of *so-called* disinfectants frequently did more harm than good. For example, when subjected to close analysis, it had not yet been determined whether or not the *real* germ of disease was destroyed by the use of the popular agent, carbolic acid, which perhaps might be regarded as substituting one bad smell for another, and not disinfection. It should not be taken for granted that merely destroying a disagreeable odor was destroying a noxious agent. Again, he believed that more stress had been laid on the presence of sewer-gas than was always sustained by the real facts in the case.

DR. C. W. CHAMBERLAIN, of Hartford, stated that it was somewhat difficult to judge just how far, in overcrowded tenement houses, in school-houses, etc., offensive gases influenced health, but, so far as the Connecticut State Board of Health had been able to determine, they had avoided any disinfecting agent which substituted one odor for another, and had eliminated carbolic acid from the list entirely.

DR. S. H. CHAPMAN, of New Haven, thought an odor simply led us to seek the cause of some putrefaction; that the odor did no harm unless it was accompanied by a germ of disease; that with mere smells the sanitarian had nothing special to do, but that stinks might be detrimental.

DR. WAGNER said that he wished to speak of odors simply as a means for detecting sources of disease, and believed that much could be learned by following them to their origin. He did not wish to suggest that the cause of noxious vapors should be treated by disinfectants.

DR. HARRISON ALLEN, of Philadelphia, then read a paper entitled

ASYMMETRY OF THE NASAL CHAMBERS WITHOUT SEPTUM DEVIATION.

The author of the paper wished simply to direct attention to this particular fact: he believed that a dif-

ference in the diameter of the posterior nares would be found to exist quite generally. He had found corresponding to it an asymmetry of the parietal protuberances, and this might perhaps be one means by which an external examination of the head might lead to the inference that the nasal passages were deformed.

DR. DELAVAN, of New York, believed that Dr. Allen, in his line of study, was doing much to reach the root of the whole discussion of all nasal difficulties; for he believed it to be the general experience that in a large number of cases attempt to relieve patients of certain nasal affections was useless simply by treating the nasal mucous membrane.

DR. RUFUS P. LINCOLN, of New York, then read a paper

ON THE RESULTS OF THE TREATMENT OF NASO-PHARYNGEAL FIBROMA, WITH DEMONSTRATION OF SUCCESSFUL CASES, TOGETHER WITH A TABLE OF SEVENTY-FOUR OPERATIONS BY DIFFERENT SURGEONS.

The object of treatment in these cases is, first, thorough removal of the growth and destruction of diseased tissue; second, avoidance, as far as possible, of accidents incident to operations in this region; third, to secure the result with the least external disfigurement. Dr. Lincoln disclaimed the idea of recommending the employment of any single method of treatment, but he believed that there was a simpler method than that so frequently employed by the most distinguished of surgeons.

The tabulated operations included those performed upon 58 patients, including three of his own cases. There were 74 operations in all, and were tabulated as follows: Of the patients, 46 were males; 8 were females, and in 4 the sex was not stated. Age: under eight years of age, 2; between fourteen and twenty-three, 31; between twenty-three and thirty, 4; between thirty-three and forty-two, 6; between forty-three and fifty-two, 5; 1 patient was fifty-four years of age, another fifty-five, and the age was not stated in 8 cases.

Of the operations involving section of the bones of the face, there were 39 performed upon 28 patients. The number of recurrences which took place within a year was 14; the number of cases reported under observation without recurrence, 4; the number of cases in which there was no record subsequent to the operation, 13; the number of deaths as a result or attributable to the operation itself, 8; in 3 other cases the operation nearly proved fatal.

Removal by knife, scissors, forceps, etc., 7 operations performed upon 7 patients. Number of recurrences, none; number of cases reported under observation one year or more subsequent to the operation without recurrence, 1; number of cases in which there was no record subsequent to the operation, 5.

Removal by the *écraseur*, or ligature, 12 operations performed upon 11 patients. Recurrence within one year, 6; under observation for one year or more without recurrence, 4; no record subsequent to the operation, 2.

Treatment by injections, cauterization, etc. Number of cases treated, 2. Recurrences within one year, 1; without records subsequent to the operation, 1.

Removal by electrolysis in 3 cases. Recurrences within one year, 1; no record after operation, 2.

Removal by the galvano-cautery *écraseur*, 11 operations performed upon 10 patients. Number of recurrences within one year, 3; under observation for one year or more without recurrence, 6; no record subsequent to the operation, 2; fatal cases, none.

Dr. Lincoln then read the report of a case in which, in January last, he removed one of these growths with the galvano-cautery *écraseur*, and subsequently destroyed the stump by the galvano-cautery. The operation performed was the same which he described to the Association four years ago. It consists in the introduction of a loop of platinum wire through the nostril, passing it behind the tumor, after which the patient is etherized, the

battery attached, the pedicle severed, and the tumor removed through the mouth.

This patient was presented, as was also the patient whom he operated upon in 1879, and another whom he operated upon in 1875, in neither of whom was there any trace of the growth remaining.

DR. W. C. JARVIS, of New York, referred to a case of myxofibroma of the naso-pharynx in which the tumor was attached to the post-nasal arch, projected forward into the anterior nares, extended some distance into the right nares, and almost entirely occluded the vault of the pharynx. He removed the growth with his *écraseur*, using a No. 5 piano-wire, and, although the strain upon the instrument was sufficient to bow the *écraseur*, the patient only complained of severe toothache and the tedium of the operation. Although the instrument in position pulsed like an artery, there was no hemorrhage following the removal of the growth. Four months afterward there was none of the neoplasm remaining.

Dr. Jarvis also exhibited a new nasal speculum, which he devised to facilitate exploration of the nasal passages, not only in these but in all other cases.

DR. ANDREW H. SMITH gave the history of a case in which he succeeded in removing the growth by means of Jarvis' snare. The pedicle, after removal of the neoplasm, grew rapidly downward but not laterally. He again applied the wire, and resorted to the application subsequently of the perchloride of iron. All that remains now is a small conical projection, which simply indicates the location of the pedicle.

DR. SEILER also referred to cases in which he had found it most satisfactory to use the cold-wire *écraseur*. In one case he had removed the growth piecemeal, the whole when it was entirely removed weighing nearly four ounces.

DR. INGALS, of Chicago, referred to three cases which he had successfully removed by means of the galvano-cautery.

DR. BOSWORTH, of New York, thought the Society was very much indebted to Dr. Lincoln for the most complete tabulation of cases which had ever been prepared, and he was very much pleased to know that the view that these tumors can be dealt with successfully without resorting to the frightful operation of Langenbeck was fully sustained by the statistics.

DR. LINCOLN thought that any one who had seen the operation of excision of the superior maxilla could not but regard it as one of the most horrible in surgery, and one of immediate hazard to the patient, and therefore any method of avoiding such a formidable operation was worthy of careful consideration and trial.

DR. E. HOLDEN, of Newark, then exhibited

A CARBON ILLUMINATOR FOR EXAMINATION OF THE THROAT AND LARYNX.

It consisted of a spring loop of wire in which a mirror could be easily slipped, was adapted to all purposes of pharyngeal and laryngeal illumination, and when attached to two ordinary Smede's cells, the illumination given was exceedingly satisfactory.

The Association then adjourned to meet at 10 A.M., May 23d.

THIRD DAY—WEDNESDAY, MAY 23D—MORNING SESSION.

The Association was called to order at ten o'clock by the President.

The first paper was read by DR. J. SOLIS COHEN, of Philadelphia, and entitled

A CASE OF THYROTOMY FOR MORBID GROWTH; WITH SUBSEQUENT DEVELOPMENT OF EPITHELIOMA IN THE CUTANEOUS CICATRIX, BUT WITHOUT INVOLVEMENT OF THE INTERIOR OF THE LARYNX.

The patient was a man, sixty-three years of age, who had persistent hoarseness of two years' duration. The

voice was a husky whisper. His general health was considerably impaired. After some general treatment Dr. Cohen removed the laryngeal growth by thyrotomy; submitted the specimen to Dr. Seiler for microscopical examination, who reported it to be papillomatous. Two years after the operation the patient presented himself with a small, soft nodule in the skin, over the right wing of the thyroid cartilage, but not attached to the cartilage. This was removed by Dr. Agnew, of Philadelphia, and submitted to microscopical examination by Dr. Formad, of Philadelphia, who declared it to be a specimen of tubular epithelioma. Ten weeks later another nodule appeared over the left wing of the thyroid cartilage, and was attached to the muscle below; this was also removed and found by Dr. Formad to be epitheliomatous in character. Finally Dr. Cohen removed all of the skin in the neighborhood which was infiltrated with epithelioma, and filled the space by making a transplantation of flaps from the upper part of the chest. The case subsequently did very well for some time, but eventually proved fatal, the patient dying in January, 1883.

Dr. Cohen regarded it as a case of epithelioma induced in the cicatrix by irritation of the neck-band, and that after the first operation the case became an example of malignant growth due to direct local irritation.

Dr. F. H. HOOPER, of Boston, then read a paper entitled

EXPERIMENTAL RESEARCHES ON THE TENSION OF THE VOCAL BANDS,

made in conjunction with Professor H. P. Bowditch, of the Harvard Medical School. Two series of experiments were performed: First, with reference to the action of the thyro-cricoid muscle, and it was proved conclusively that the action of this muscle was to draw the cricoid cartilage upward upon the thyroid cartilage. The second series was to determine the effect of the air-blast, and it was proved that in addition to the entire rise of the larynx in singing high notes there is an excessive rise of the cricoid cartilage upon the thyroid, a phenomenon to which attention has not heretofore been called.

The paper was elaborate, technical, illustrated by diagrams and apparatus, and exhibited a remarkable amount of careful research and experimental application.

Dr. Hooper believed that the following facts had been established: First, that with high pressures the cricoid cartilage invariably moves more than the thyroid, and he believed it to be a correct inference that with all pressures such was the result. Second, that with high pressures, after section of the muscles, both cartilages moved upward more freely, but the stretching of the vocal bands is less.

The conclusion reached concerning the effect produced by the air-blast was, that air escaping from the lungs produced decided upward movement of the cricoid cartilage, in addition to the general rise of the larynx, the upward movement increasing in proportion to the force with which the air is expelled from the chest.

Dr. Hooper thought his researches might possibly offer a suggestive clue in elucidating certain pathological conditions. For instance, cases where the singing voice can be relied upon while in the same individual conversation is impossible, might perchance, in a measure, be explained by this action of the air-blast as a tensor at high pressures.

The general conclusions reached by the author of the paper were: 1, That the cricoid cartilage is the most movable part of the laryngo-tracheal tract; 2, that the thyro-cricoid muscle should be described as *arising* from the thyroid cartilage, and *inserted* into, and giving motion to, the cricoid; 3, the air-blast is a direct and important longitudinal tensor of the vocal bands.

Dr. BEVERLEY ROBINSON, of New York, then read a paper on

AURAL COMPLICATIONS OF INFLAMMATORY CONDITIONS OF THE NOSE AND THROAT.

The author of the paper believed it was very impor-

tant for laryngologists to be familiar with the aural complications incident to the diseases of the naso-pharyngeal space, and first directed attention to aural complications accompanying *acute* nasal and throat disease of inflammatory character; and, second, to the aural complications accompanying *chronic* inflammatory conditions of the nose and throat. The aural complications, such as occurred in connection with scarlet fever, diphtheria, measles, typhoid fever, and other acute general diseases and febrile affections, were discussed at considerable length. The author believed that the complications were due not, as a rule, to direct extension from the nose and throat through the Eustachian tube to the ear, but to the same cause which produced the general disease. He believed that disease of the middle ear was much more likely to occur as a complication in case of chronic inflammatory affection of the throat and nose than in those cases in which these diseases were not present. In conclusion he urged upon laryngologists the importance of guiding their patients, especially with reference to the hygiene of the ear.

Dr. MACKENZIE, of Baltimore, directed attention to one agency which had not been mentioned by the author of the paper—namely, the reflex production of disturbance in the ear, originating in irritation in the nasal passages. He had been able to produce artificial redness of the drumhead by irritation of the turbinated structures of the nose. Many of these cases belonged to the class which went first to the aurists, and were told that there was nothing the matter with the ear, and then to the laryngologists, who told them there was nothing the matter with the throat or nose, and he believed that they were largely reflex in character.

Dr. JARVIS, of New York, referred to cases in which hypertrophy of the posterior nasal mucous membrane is accompanied by deafness, and also to the influence of deviated septum in the production of aural disturbance, believing that the aural complication was due not so much to the deviation of the septum and disturbance of pneumatic conditions of the nasal and aural chambers as to the fact that a certain amount of inflammatory disease was usually present in connection with this change in the organic structure of the nose.

Dr. ROBINSON believed that certain cases could be best explained in the manner referred to by Dr. Mackenzie. Within the past six months he had seen several cases which sustained the conclusion which he had previously reached that obstruction of the nasal passages and deviation of the nasal septum has not so much to do with the aural difficulty as we had, perhaps, heretofore been led to believe.

Dr. D. BRYSON DELAVAN then read a paper entitled
TWO POINTS IN THE ANATOMY OF THE LACUNÆ TONSILLARUM.

The special points to which the author of the paper directed attention were, first, the existence of large single cavities in the interior of each one of the tonsils, which includes several follicular folds and procures their common discharge at the periphery. By this arrangement the actual superficial extent of the tonsil is increased. The second point was the unusual destructibility of the attenuated mucous membrane in the depth of these large lacunæ, a point worthy of attention because it constitutes a factor in the pathology and treatment of the diseased condition of the gland.

The Association then adjourned to meet at 3 P.M.

THIRD DAY—AFTERNOON SESSION.

The Association was called to order at 3 P.M. by the President.

Dr. G. W. MAJOR, of Montreal, read a paper on
THE VALUE OF POST-LARYNGEAL PAPILLOMATA AS A MEANS OF DIAGNOSIS IN TUBERCULAR DISEASE.

Of these papillomata he recognized two varieties: 1, the velvety; 2, the filamentous, or feathery; probably

two degrees of the same disease. The histories of several cases were given, in which by the existence of these growths he had diagnosticated tubercular disease.

DR. M. J. ASCH, of New York, said he had frequently observed this peculiar appearance in the larynx in cases of tuberculosis, but it did not seem to him that they should be regarded as absolutely diagnostic of that disease, because he had seen the same velvety appearance in other cases as well. For example, they were frequently associated with asthma.

DR. MAJOR said he quite agreed with Dr. Asch, that where the velvety appearance existed there was not necessarily actual pulmonary complication, but he had always found tubercular tendency and tuberculosis in the family. This was the more important condition to recognize because; so far as he had observed, after the filamentous growths had appeared recovery had not taken place.

DR. E. C. MORGAN, of Washington, then read a paper on

PHARYNGEAL TUMORS.

with the report of a case of enormous tumor removed from the glosso-epiglottic sinus, with remarks. The tumor was two and one-fourth inches in its lesser, two and three-fourths inches in its great circumference, and had a pedicle one-fourth of an inch long, which could be readily grasped between the tips of the middle and index fingers, and *with the fingers* he twisted the tumor from its attachment. The common opinion that purely pharyngeal tumors are rare, he thought was erroneous, because he had found sixty-one reported cases, extending over a period of seventy-one years. He included in this class only those tumors which originated within the pharynx or extended into the inferior pharynx. Of the sixty-one cases fourteen were sarcomata and ten fibromata. The interest in his case centred in the rarity of pedunculated sarcomata in this region, the size of the tumor and the method of removal.

The paper was discussed by Drs. De Blois, of Boston; Ingals, of Chicago; Delavan, Lincoln, Asch, and Bosworth, of New York.

DR. M. J. ASCH, of New York, then reported

A CASE OF SUDDEN DEATH OCCURRING AFTER TRACHEOTOMY.

There was nothing peculiar in the operation, and two days subsequently the patient was progressing favorably. Soon after visiting the patient with his assistants, and finding him doing well, he was summoned to hasten back, and on his return found that the man had fainted. From this he rallied, but soon after went into collapse and died within a few minutes.

At the autopsy nothing was found to account for the sudden death.

Dr. Asch believed that in the majority of cases in which there is obstruction in the larynx, tracheotomy is an exceedingly difficult operation; and that when it is performed for obstruction, whether acute or chronic, however easy its performance might be, tracheotomy should not be viewed in any light except that of a serious surgical procedure.

DR. ANDREW H. SMITH, of New York, read the next paper, on

ADHESION OF THE VELUM TO THE WALLS OF THE PHARYNX.

This condition is one of the results of ulceration, almost invariably of syphilitic origin, and belonging to the tertiary stage. Inflammation of the middle ear almost always occurs as a complication. In cases of complete adhesion the sense of smell is always absent and the sense of taste is lost or greatly impaired. The treatment is by dilatation with bougies, and this method failing, by cutting operations. In connection with the latter, Dr. Smith spoke of the use of monochloro-acetic acid to prevent adhesion of the cut surfaces, the peculiar action

being that healing goes on perfectly under the eschar formed by this agent.

The paper was discussed by Drs. DeBlois, of Boston, and Ingals, of Chicago.

The Association then elected as officers for the ensuing year: *President*—Dr. Frank H. Bosworth, of New York; *First Vice-President*—Dr. S. W. Langmaid, of Boston; *Second Vice-President*—Dr. S. Johnston, of Baltimore; *Member of the Council*—Dr. Beverley Robinson, of New York; *Librarian*, Dr. T. R. French, of Brooklyn.

The two retiring Vice-Presidents, Dr. C. Seiler, of Philadelphia, and Dr. E. F. Ingals, of Chicago, as a committee, conducted the President-elect to the platform, and Dr. Lefferts in a few well-chosen words retired from the office, the duties of which he has so satisfactorily discharged. The President made a few appropriate remarks, and then declared the Association adjourned, to meet in New York on the third Monday in May, 1884.

CONNECTICUT MEDICAL SOCIETY.

Ninety-second Annual Convention, held at Hartford, Conn., May 23 and 24, 1883.

(Continued from p. 575.)

SECOND DAY—THURSDAY, MAY 24TH.

The Society was called to order at nine o'clock by the President.

REPORT OF SECRETARY.

DR. CHAMBERLAIN, the Secretary, presented the report of the year, stating that the prosperity of the Society had been uninterrupted; never had it included so nearly all of the regular practitioners of the State, nor had its financial condition been better. The death-rate had been unusually large, the Society losing fourteen members and one honorary member, Dr. Wm. Pierson, of Orange, N. J. Of these, many were from the oldest and most active members. Almost all left an unspotted name, and some a reputation extending beyond their own State and land. Dr. Geo. B. Hawley, in the Hartford Hospital, left an enduring monument of faithful endeavor, and has been an unwearied worker in humanitarian labors. Dr. E. P. Bennett's fame as a surgeon was not limited by the borders of his own State.

In retiring from the office held by their favor for the past eight years, the Secretary desired to express his thanks for the cordial support received from the Society, which made it possible for him to retire from service while the Society was in such a flourishing condition. During eight years, in spite of a loss by death of eighty-six members, the net gain in numbers had been a little over a hundred. The Society now numbered four hundred and sixty, while the amount in the treasury was more than a working balance, and would enable the Society to allow some compensation to the Secretary and soon to reprint the earlier Transactions.

DR. WHITE moved that the sincere thanks of the Society are hereby tendered to Dr. Chamberlain for his long, faithful, and arduous services as Secretary for the past eight years.

DR. WILE referred to the appreciation of the work of the Secretary, the prompt appearance of the Transactions, and moved that a committee be appointed to have an appropriate series of resolutions engrossed and presented to the Secretary, as an expression of our appreciation for his services. The resolution was passed unanimously, and the President appointed Drs. W. C. Wile, M. C. Hazen, and Geo. S. Porter on this committee.

The PRESIDENT then presented his

ANNUAL ADDRESS

on the country doctor, which was in practical form, and was a witty résumé of the trials, labors, and rewards of the country doctor, and elicited repeated applause by the faithful pictures presented.

On motion of DR. PORTER, the thanks of the Society were voted the President for his address. Delegates were presented from Rhode Island and Massachusetts, and Drs. M. Henry and G. Sawyer, of New York, were invited to be present as guests of the Society.

DR. WAINWRIGHT presented his report on matters of general interest, and deferred the presentation of the cases until after the reading of essays.

PROFESSOR M. WHITE, of New Haven, then exhibited and described

AN IMPROVEMENT IN MICROSCOPIC MEASUREMENT

of his invention, with a brief essay on the subject, in which the merits and defects of different instruments were described. His invention was a method of delicate measurement, by the introduction of a micrometer in the microspectroscope. He placed above the instrument a telescope of low magnifying power, the eye-piece having a Jackson micrometer and the field-piece of equal power.

DR. WILLIAM C. WILE related

A CASE OF EXTIRPATION OF THE UTERUS,

unsuccessful, but performed under unfavorable circumstances, but demanded by the condition of the patient, who lived five days. The specimen was exhibited and the operation described and discussed.

He also related a case treated by the most eminent specialists of New York for

MYELITIS OF THE CORD.

The man, aged forty-five, had had morbus coxarius, with recovery. He presented all the symptoms of myelitis paraplegia and the like after he returned from New York. Dr. Wile discovered an

ABSCESS IN THE ILIAC REGION,

which, the patient insisted, should open itself. After discharging an enormous quantity of pus he suffered great pain. The doctor opened the hip and found that the head of the femur was absorbed two inches, diseased, and that there was a burrowing abscess reaching to the scapula. Exsection resulted in complete cure.

He also related a recent case of

EXCISION OF THE TIBIA;

disease of bone resulted from an injury three years previous, resulting in osteitis.

DR. BURKE related a

COMPLETELY SUCCESSFUL CASE OF EXTIRPATION OF THE UTERUS,

up to the present time.

DR. GEORGE S. PORTER presented a specimen of

EXTRA-UTERINE PREGNANCY.

The head of the child extended out of fimbriated extremity, which increased the length of the neck to a very considerable degree. The woman died of asthenia.

DR. WHITE related a case where twenty-two calculi were found in the bladder, in a cul-de-sac, behind a greatly enlarged prostate. Outside the bladder, in the cellular tissue, were fifteen concretions the size of a pea. One examined was found to be composed of phosphate and carbonate of lime.

DR. BROWNSON then moved that

DR. M. HENRY, of New York, by invitation, present his views on the operation for varicocele.

DR. CHAMBERLAIN related two cases where Henry's method had been used successfully and very satisfactorily by Dr. Jarvis, of Hartford.

DR. GEORGE L. PARMELE presented an essay on

POINTS IN ORAL SURGERY,

of interest to physicians. He referred particularly to

THE RELATIONS OF DISEASED AND OF IMPERFECT TEETH TO DIGESTIVE TROUBLES,

constipation, diarrhoea, and dyspepsia, and of the nervous connections and reflex influences which induce disease, directly and indirectly. Such patients were often treated years for troubles that a dentist relieved at once. Diseased teeth induce many other troubles than neuralgia, although the latter is the only one generally recognized.

The thanks of the convention were voted to Dr. Parmele for his essay.

DR. G. W. RUSSELL spoke of the unsatisfactory condition of the essay records of the Society, and moved that the Secretary be authorized to condense and print the

TRANSACTIONS OF THE FIRST TWENTY-FIVE YEARS OF THE SOCIETY,

and offered to be responsible for one hundred dollars for that purpose. The resolution was passed.

DR. W. H. HOLMES read an essay on

ASPIRATION OF THE CHEST IN PLEURISY.

The pathology of the various forms of the disease was described, and the danger of allowing effusions to remain for a long time was referred to. Under such circumstances absorption takes place, and the advantages and results of aspiration are prevented.

DR. F. N. BRAMAN presented an essay on

COMPLICATIONS OF LABOR,

illustrating many unusual difficulties and the methods used to counteract them. Hour-glass contractions, and the fillet and pressure inversion were discussed.

The paper was discussed by PROFESSOR F. E. BECKWITH. He did not think the length of the symptoms was the cause of death, but that peritonitis ensued only when the maternal tissues were injured. Winding the fillet around the body he regarded as a new suggestion by Dr. Braman, but thought the fillet around the shoulders would accomplish the same purpose.

DR. BRAMAN said that the use of the fillet around the body was to obtain complete control of the child in rotation.

DR. AMBROSE BEARDSLEY then read a paper on

THE TREATMENT OF MALARIA.

The method advocated was a brisk purgative—aloes, blue mass, and capsicum—an alterative and an aromatic tonic, with some alkali. This treatment had been very satisfactory in his hands, even when quinine in large doses had failed.

The following resolution, offered by DR. G. R. PORTER, was passed: That the Secretary be requested to communicate with the County Societies with reference to the publication of the Transactions of the Society to 1830, to see if they would bear their share of the expense for the same.

On motion of DR. BACON, the remaining papers were referred to the Publication Committee and read by title.

The report of the committee to examine students at Yale Medical School was read and ordered published.

The Society then adjourned for the annual dinner at the United States Hotel. The next session will be held at New Haven. The attendance was large, all parts of the State being represented.

THE MEDICAL DEPARTMENT OF THE SYRIAN PROTESTANT COLLEGE in Beirut, Syria, says the *Evangelist*, is in need of a Professor of Anatomy, Physiology, and Histology. Instruction is to be given in the English language. The applicant should be a graduate of a medical college, of high standing, and a man of earnest missionary spirit, who would enter upon the work for the sake of promoting the spiritual welfare of his pupils, and aiding in the advancement of the Church of Christ in Syria. The Rev. Dr. H. H. Jessup, now of 23 Centre Street, New York, may be addressed for particulars.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE DEBATE ON DIABETES AT THE PATHOLOGICAL SOCIETY—THE PROBABLE REPEAL OF THE CONTAGIOUS DISEASES ACTS—SCHOLARSHIPS IN MEDICINE AND THE SOCIETY OF THE APOTHECARIES.

LONDON, May 5, 1883.

THE debate on diabetes at the Pathological Society was concluded on Monday last. It seems to have led to no definite conclusion as to the pathology of the disease, but some interesting facts and opinions were brought forward.

Dr. Seymour Taylor described some changes he had found in cases of diabetes. They presented the usual vascular engorgement, but in addition, the epithelium presented a remarkable appearance. The cells were large, brownish, their nuclei did not take the logwood stain, and the cells had a tendency to come away *en masse*, so in many parts the kidney presented a mere skeleton of its former condition.

Dr. F. Taylor considered that we had no evidence of any definite lesions. He referred to the large number of deaths from "diabetic coma." He also mentioned the frequency of severe abdominal pain as an early symptom—an important fact to bear in mind, as it might lead to error in the diagnosis.

Dr. Dickenson defended the doctrine of the association of diabetes with cerebral lesions, and described lesions he had observed. He had found extravasations of blood in seven out of fifteen brains from patients dying with diabetes.

Dr. Pavy maintained that the blood was at fault. The glucose in diabetic urine was, he considered, produced by a glucose-forming ferment found in the liver. Venous blood was antagonistic to this ferment, but arterial blood in the liver produced it. Diabetes depended on a dilatation of the arteries of the chylipoietic viscera (by vasomotor paralysis) which allowed the blood to pass to the liver too little deoxygenated. Dr. Pavy described several experiments he had made.

Since the vote on Mr. Stansfeld's motion in the House of Commons, orders have been issued to the police in the districts where the Acts are in force that they are to cease performing their duties in relation to the Acts. A discussion on the subject in the House of Commons is expected in a few days, and a Bill to repeal the Acts will probably be brought in.

The Society of Apothecaries has instituted two scholarships in medicine, of the annual value of £100, and each tenable for two years. They are open to all students of between four and five years' standing, who have obtained a qualification. They are also about to add a practical examination in chemistry to the first examination for the L.S.A. These changes are no doubt in view of coming legislation. The Apothecaries Society no doubt wish to make out a case for their survival, and intend to protest against their representative being dropped from the new medical council. The general opinion seems to be that, although the Society has done good work in the past, it is not needed now. In the case of the Irish Apothecaries Society, whose representative has also been dropped, it was only by an error that a clause empowering it to grant medical diplomas was ever inserted in the Medical Act of 1858.

CONCERNING THE DEGREE OF M.B.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the number for May 5th, which reached me today, I notice some extracts from a letter by Dr. Parke commenting upon a letter from my pen. Dr. Parke is incorrect in stating that gentlemen who are only M.B.

are addressed as Mr. Although not in strict law entitled to term themselves Dr., as a matter of courtesy the title is always given them, and it may almost be said to have grown into a right. Many London physicians attached to important hospitals are only M.B., and every one calls them Dr. As an example, I may mention Dr. Lionel Beale (M.B., London), a name doubtless well-known to your readers. Many of our universities do not require any examination to pass from M.B. to M.D., but merely the writing of a thesis, a short term of residence, or in some cases merely the payment of a fee. The London University holds a special examination for its M.D. in two subjects: 1, Medicine; 2, Logic and Psychology, and is the only university which denies to its Bachelors of Medicine the title of Doctor. Nevertheless they assume it and are addressed as such by others. I am aware that some M.B.'s call themselves Mr., but then they are surgeons. Some surgeons are M.D. and yet call themselves Mr., e.g. the late Mr. Soelberg Wells.

In speaking of physicians, Dr. Parke seems to forget that the word physician is used in a different sense in England to what it is in America. My remarks applied to *pure physicians*, i.e., practitioners who prescribe and only practise pure medicine. I beg to repeat that in London, at any rate, nearly all physicians are graduates of some university. The L.R.C.P. is a physician's diploma, but merely a license to practise, which was instituted for general practitioners. Its possession does not make its holder a physician and the majority of those who hold it are in general practice and supply drugs. It is an entirely different thing to the M.R.C.P. which can only be held by those who practise as pure physicians.

I am sir, yours faithfully,

YOUR SPECIAL CORRESPONDENT.

LONDON, May 15, 1883.

PELVIC HÆMATOCELE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the excellent *résumé* you have given in the last number of THE RECORD of the recent transactions of the West Virginia Medical Society occurs a report by Dr. R. W. Hall of a surgical interference in a case of pelvic hæmatocele, with consequent general peritonitis, and final recovery of the patient. In this case the temperature and pulse had been normal up to the moment of the advent of the consulting physician, who found a round, hard tumor in the hypogastric region, exceedingly tender to the touch, the contents of which were aspirated two days afterward. It would seem there was no immediate necessity for such an operation, if at all, as the tenderness was due to local peritoneal inflammation usual in such cases, and since the aspirator could not remove the coagulum, the chief source of septic absorption, nothing was gained by it.

The surgery of twenty-five years ago conscientiously advocated the speedy evacuation of such tumors, but experience has limited its interference to an exceedingly small number of cases, and only where long chronic disorder has not resulted in absorption, and where septic influences begin to appear.

Even Nélaton, who once popularized surgical interference, by experience was taught "to proscribe it in an almost absolute manner." Priestley shows that the mortality in surgical operations for the relief of hæmatocele is one in four, while by the expectant method it is but one in nine. Nonant lost but one case in fifteen, and Hewett none out of eleven treated by the expectant plan.

Fritsch writes: "Hæmatoceles treated by operative opening have run a particularly dangerous and malignant course. Rapid sloughing, sepsis, and death, or long-continued, debilitating suppuration and pyæmia have ensued."

In a very severe case of hæmatocele reported by me, and published in the "Transactions of the Medical Society of New Jersey," 1875, the tumor was of extraordinary size,

extending nearly to the umbilicus. Septicæmia was feared, peritonitis existed, and yet after all the alarm, the contents were suddenly evacuated per rectum in copious discharges, while all the symptoms disappeared like magic.

One other case occurred in my practice last year which further illustrates the wisdom of the expectant plan. Mrs. A. T. A—, of Holmdel, on June 9th, had the hardihood to submit to uterine examination at the hands of a homeopathic non-expert in Brooklyn, who finding no special lesion proceeded to make one by injecting some corroding fluid into the uterus. Immediately Mrs. A— was seized with sharp pains about the organ, and crying out, was hastily assisted from the table, when she experienced a sensation as though the uterus was about to escape bodily from the pelvis. She was carried in a fainting condition to the house of a friend, where she remained in great suffering for two days. On the 13th I was called to see her, at her house in the country, where she had been removed the day before, on a mattress, by train and private carriage. Her countenance indicated extreme prostration. There was pelvic pain with tympanites, coldness of the extremities, nausea, and suppression of the urine. The vagina was cool, but the speculum showed recent erosion of the os, as did the upper part of the vagina, and the vulva was inflamed from an acrid discharge, the result of the maltreatment of the 9th. Her underclothing on the evening of that day bore unmistakable stains of the caustic fluid. In the hypogastric region I discovered a tumor of considerable size, which I was assured had never been noticed until the Friday night previous.

Not to impose upon you the long description of subsequent symptoms and treatment, I hasten to say that, absorption not having occurred by August 20th, I felt called upon to evacuate the contents of the tumor, for fear of abscess and septic poisoning, the patient continuing in a low condition. Great difficulty occurred in selecting a proper point for incision, much cellular tissue remaining between the vagina and tumor. The operation was deferred for a few days.

August 20th a discharge of about sixteen ounces of fetid matter escaped from the vagina. The tumor became greatly reduced and gradually disappeared. The patient shortly afterward was able to drive out, and in a few weeks regained her usual health.

Very truly yours,

GEO. T. WELCH, M.D.

KEYPORT, N. J., May 21, 1883.

BARTHOLOW VERSUS WALLIAN, AND ATROPIA VERSUS MORPHIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: You have had in your valuable journal some very excellent pieces on "Medical Latin." Now it does seem to be time for some one to say a word on Medical Arithmetic. All your readers are, I suppose—I know they all ought to be—interested in the antagonism of atropia *vs.* morphia. This is a very important subject as well as a very interesting one. Opium-poisoning is a very common cause of death, and in our civilization seems to be getting more so. We are all deeply interested in the antidotal powers of atropia, and in trying to fix some approximate ratio of the two poisons. With these feelings I turned with avidity to Dr. Wallian's article in THE RECORD of May 5th, but was greatly disappointed that so excellent an article was so marred by mistakes in calculation. What dose did he give? He says he made a solution of gr. j. to 3 ij., and gave ℥xij., or $\frac{1}{20}$ gr. Now it is plain that ℥xij. is $\frac{1}{10}$, not $\frac{1}{20}$ gr. So, again, when he finds it necessary to "double his dose," he seems to quadruple a dose already twice as large as he thought it was. He doubled the strength of his solution, and then doubled the quantity administered, making $\frac{4}{10}$ instead of $\frac{1}{10}$. (See MEDICAL RECORD, May 5, 1883, p. 487.) This seems to be rather "mixed mathematics." His

worst cases seem to have gotten $\frac{6}{10}$ gr. atropia to antidote a dose of morphia estimated at not more, certainly, than $4\frac{1}{2}$ gr., or about 1 of atropia to $8\frac{1}{2}$ morphia. This, so far from being less than Bartholow recommends, is two and a half times as much, and is the largest relative dose I have seen suggested. Bartholow says 1 to 20. (See his admirable Cartwright Lecture, in THE MEDICAL RECORD of November 27, 1880, p. 593.) Surely this subject is of enough importance to make a gentleman who writes a piece otherwise so valuable a little more careful with his fractions. Very respectfully,

HORACE P. LACY, M.D.

SMITHVILLE, CHARLOTTE COUNTY, VA., May 22, 1883.

SUTURE CLAMP COAPTATION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The note by Dr. Cipperly on "Suture Clamp Coaptation" in to-day's RECORD suggests the following: A case of instruments, made by Tiemann & Co., selected by Dr. Keyes, and given to me Christmas, 1879, contained a number of spring-clamps similar to those described by Dr. Cipperly, and a detached handle by which they could be easily and quickly applied.

Further, I have read, but do not remember when and where, that in Central or South America the natives use the nippers of large beetles for the same purpose. The sides of the wound are held together, the beetle is made to seize it transversely, and then the head of the insect is cut off. The nippers retain their hold until removed.

While Dr. Cipperly must, I think, abandon the claim to priority, he may well find satisfaction in the thought that he has recognized a positive surgical need, and has independently devised an efficient method of meeting it.

Very truly,

L. A. S.

May 26, 1883.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 19, 1883, to May 26, 1883.

CAMPBELL, JOHN, Lieutenant-Colonel and Surgeon. Medical Director, Department of the South; granted leave of absence for one month, on surgeon's certificate of disability. S. O. 50, par. 3, Department of the South, May 21, 1883.

BURTON, HENRY G., Captain and Assistant Surgeon. Now awaiting orders at St. Paul, Minn., assigned to temporary duty at Fort A. Lincoln, D. T. S. O. 83, par. 1, Department of Dakota, May 15, 1883.

PORTER, J. Y., Captain and Assistant Surgeon. Assigned to duty at Fort Davis, Texas. S. O. 49, Department of Texas, May 14, 1883.

SPENCER, WM. G., Captain and Assistant Surgeon. Assigned to duty at Fort Hamilton, N. Y. H. S. O. 83, par. 2, Department of the East, May 14, 1883.

GORGAS, W. C., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month. S. O. 51, par. 5, Department of Texas, May 17, 1883.

HOPKINS, WM. E., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Whipple Barracks, Arizona Territory. S. O. 44, par. 2, Department of Arizona, May 14, 1883.

MACAULEY, CARTER N. B., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Bennett, Dakota Territory. S. O. 83, par. 2, Department of Dakota, May 15, 1883.

MCCREERY, GEORGE, First Lieutenant and Assistant Surgeon. To report for duty to the commanding officer of troops in the field near San Bernardino Springs, Arizona Territory. S. O. 44, par. 1, Department of Arizona, May 14, 1883.

RAYMOND, H. I., First Lieutenant and Assistant Surgeon. Relieved from duty with troops in the field near San Bernardino Springs, Arizona Territory, and ordered to return to his proper station, Fort Apache, Arizona Territory. S. O. 44, par. 1, Department of Arizona, May 14, 1883.

WILSON, GEORGE F., First Lieutenant and Assistant Surgeon. Upon being relieved as Post Surgeon at Fort Townsend, Washington Territory, assigned to duty at Headquarters, Department of the Columbia. S. O. 64, par. 2, Department of the Columbia, May 10, 1883.

WILSON, GEORGE F., First Lieutenant and Assistant Surgeon. To report to First Lieutenant Frederick Schwatka, Third Cavalry, for duty in connection with explorations in the Department of the Columbia. S. O. 64, par. 3, Department of the Columbia, May 10, 1883.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending May 29, 1883 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
May 22, 1883.....	4	4	128	8	170	41	0	0
May 29, 1883....	0	5	132	4	163	39	0	0
Deaths.								
May 22, 1883.....	0	1	32	7	27	14	0	0
May 29, 1883.....	2	4	30	6	25	19	0	0

The total mortality for the week ending May 19, 1883, was 728, of which 70 were from pneumonia.

DR. CAROLINE S. PEASE, a member of the Rensselaer County Medical Society, has been appointed a member of the staff of the Troy Hospital, Troy, N. Y., taking the department of obstetrics and diseases of women and children.

FOLLOWING GREAT NAMES INTO DOUBTFUL THINGS.—The *Christian Advocate* of the 17th instant, in an editorial under the above caption, after inveighing against the misuse of great names in boosting up doubtful enterprises in stocks, manufactured goods, and speculations in general, puts the case thus : "Take no medicine on the testimony of the Rev. Father Open Mouth," who took two bottles and found himself a new man, "or the member of Congress who was extricated from the very jaws of death." He that is looking for a leader will surely find him. He who is willing to be deceived will not wait long. To follow saints when you doubt whether it be right, is little better than to follow sinners when you do not know that they are wrong. The wrecks of those who have blindly followed great names into enterprises doubtful as to their honesty, doubtful as to their financial results, doubtful as to their effect in reputation, are probably as numerous as of those who have been swindled by scoundrels, and fleeced by professional confidence men.

THE NATURE OF THE BITE OF THE LEECH has been examined by M. Carlet. He detached the animal from the shaved shin of a rabbit at different stages. Suppose a scarifier, with three toothed and equidistant blades withdrawing from one another while they press into the skin, and operating several times successively in the same place ; this gives a pretty exact idea of the mechanism.

HYGIENIC VALUE OF MIRTH.—But, aside from all this, mirth has an hygienic value that can hardly over-rated while our social life remains what the slavery of vices and dogmas has made it. Joy has been called the sunshine of the heart, yet the same sun that calls forth the flowers of a plant is also needed to expand its leaves and ripen its fruits ; and without the stimulus of exhilarating pastimes perfect bodily health is as impossible as moral and mental vigor. And, as sure as a succession of uniform crops will exhaust the best soil, the daily repetition of a monotonous occupation will wear out the best man. Body and mind require an occasional change of employment, or else a liberal supply of fertilizing recreations, and this requirement is a factor whose omission often foils the arithmetic of our political economists. To the creatures of the wilderness affliction comes generally in the form of impending danger—famine or persistent persecution ; and under such circumstances the modifications of the vital process seem to operate against its long continuance ; well-wishing nature sees her purpose defeated, and the vital energy flags, the sap of life runs to seed. On the same principle an existence of joyless drudgery seems to drain the springs of health, even at an age when they can draw upon the largest inner resources ; hope, too, often baffled, at last withdraws her aid ; the tongue may be attuned to canting hymns of consolation, but the heart cannot be deceived, and with its sinking pulse the strength of life ebbs away. Nine-tenths of our city children are literally starving for lack of recreation ; not the means of life, but its object, civilization has defrauded them of ; they feel a want which bread can only aggravate, for only hunger helps them to forget the misery of ennui. Their pallor is the sallow hue of a cellar-plant ; they would be healthier if they were happier. I would undertake to cure a sickly child with fun and rye-bread sooner than with tidbits and tedium.—*Popular Science Monthly*.

THE FREE CLINIC MANIA.—A writer in the *New York Medical Journal* says that in Buffalo, N. Y., there are nine free dispensaries either under way or starting. Further, he says : "Under the pretence of charity the physicians thus seek to advertise their names to the public, and jealousy has caused the dispensary mania to become epidemic, no one wishing to be outdone by another in the scramble for a vast acquaintance."

AN OLD PRACTICE ADHERED TO.—At the recent meeting of the Louisiana State Medical Society the following resolution, which needs no comment at our hands, was adopted. There seems to be a new and original school of virus attenuators in that State :

"Whereas, This society is informed that it is the practice of one or more practitioners of medicine within the limits of this State to inoculate human subjects with lymph or pus taken from small-pox patients, previously mixing it with milk or cream ; therefore be it

"Resolved, That the practice of inoculating small-pox by mixing any product whatever from the body of a small-pox patient with milk, cream, butter, or any fluid obtained from the cow, is productive of no modification beyond that of direct inoculation from one person to another. It does not deprive the person thus inoculated of that power to communicate the disease through the atmosphere, which naturally small-pox possesses, and is therefore dangerous to public health."

LEFT-SIDE PAIN.—At a recent meeting of the Academy of Medicine, in Ireland, Dr. Wallace Beatty read a paper on this subject (*Medical Press and Circular*). He considers the pain, in many instances, due to fecal accumulation, and it can be removed by getting rid of the accumulation. The pain is felt over the lower few ribs on the left side, associated with great pain on upward pressure of these ribs, but no pain on downward pressure. He ascribes the pain to the dragging of a loaded colon on the pleuro-colic ligament, setting up extreme irritability of the nerves.

FILTH DISEASES IN RURAL DISTRICTS.

By ALFRED L. CARROLL, M.D.,

NEW BRIGHTON, N. Y.

AN editorial comment in THE MEDICAL RECORD of April 14th, upon a paper by Dr. Hamilton, of Philadelphia, may serve as an apology for some remarks on a subject which ordinarily seems to possess scarcely more interest for practising physicians than for "practical" laymen; both being wont to lay the finger of incredulity against the nose of scorn when they turn their deafest ears to the voice of the sanitarian. In the present very unsettled condition of professional opinion as to the diagnosis of typhoid fever—passably good authorities in India, on Western mountain peaks, and even nearer home, differing widely thereanent—I shall not attempt here to discuss its etiology, or to single out for reprobation any particular one of the several kinds of bacteria which have been respectively described as its exclusive cause. Suffice it merely to hint that there may be a possible source of error in statistical arguments touching its relative frequency in town or country. But, waiving this, I am not aware that "professed sanitarians" have ascribed to "sewer-gas" alone such pre-eminence over other vehicles of filth or fungi as the article in question imputes. On the contrary, I believe that the majority of cases of enteric fever which have been traced accurately to their origin have been traced to other and more tangible contaminations of food or water. Nevertheless there is strong evidence, which has stood the test of much cross examination, that the so-called "filth diseases" deserve their name in this respect: that, whatever be the specific *tertium quid* which determines their occurrence in the individual, filth-poisoning (*i.e.*, the imbibition, through some channel, of the products of organic decomposition) is an essential factor in their genesis.

The first source of fallacy in the arguments referred to lies in the misinterpretation of the term "sewer-gas," connecting it with sewers in particular instead of with sewage in general. Thus, I find it stated that typhoid is "more prevalent in the suburbs and surrounding country than in the cities subjected to the contamination of sewer-gas"; that diphtheria and scarlatina occur most fatally "in the country, where sewer-gas is wanting"; and that in Philadelphia the extension of the sewerage system into the rural sections has diminished the sickness from fever. Now, the facts on which most sanitarians lay great stress are, that unsewered rural districts are more exposed to danger from fermenting filth than cities; that the ineffable atrocities of leaching cesspools and privy-vaults (those perversions of barbarism to which the American rustic clings as to his most precious birthright) do infinitely more to poison air, and soil, and water than all the blunders of city engineers and plumbers combined; and that, granting the worst that can be said of some city sewers which shall be nameless, even a bad sewer is better than none at all—which is merely equivalent to saying that it is better to carry away as much of one's sewage as possible than to keep the whole of it on the premises to decompose under one's nose. And the peril from this fount and origin of evil is augmented a hundred-fold where the mania for "modern improvements" has invaded rural households. Long before sewers are

thought of—even before the importation of the agonizing pianoforte—the suburban housewife insists on having a bath-room, including that sum and substance of vileness, a pan water-closet, on the bedchamber floor, and a kitchen sink and "stationary tubs" down-stairs; and these fixtures, commonly constructed in the cheapest and nastiest manner, are connected with an unventilated cesspool, serving as so many inlets to insure the constant pollution of the house atmosphere with the gases of decomposition. Then, in an uncemented basement a "portable furnace" is arranged to transport to the upper rooms, not only the cellar-air, but the freely indrawn "ground atmosphere," laden with noxious vapors from the soil-soakage of cesspools or privies. It is not saying too much to affirm that for every one channel of filth-poisoning in a paved and sewered city there are at least three in the average village settlement, and if the evidence of insanitary conditions be found in "not more than one house out of five," it is because, unfortunately, very few physicians in this country have cared to learn how to look for it—familiarity with the doses of drugs and the results of disease being regarded in most of our medical schools as vastly more important than *rerum cognoscere causas*.

I am not sufficiently informed of the morbidity statistics of African cities to appreciate the full weight of reasonings based upon their alleged comparative salubrity; the occasional scattered returns which I have seen from a few of them show death-rates ranging from 30 to over 40 per 1,000. But I am free to admit, on general principles, that it is less dangerous to let organic matter decompose fully exposed to atmospheric oxygen than to store it in unventilated receptacles to form sulphuretted and carburetted compounds, or to saturate an undrained soil with it. It is to be remembered that few, if any, sewage substances are suspected of pathogenic power while in their fresh solid or liquid state; the products of their subsequent chemical changes are what we have to fear; and if these products be liberated *al fresco* as fast as they are formed, they are diluted to homœopathic insignificance by the surrounding air. Of the two evils, therefore, the Africo-Hibernian practice of throwing house-refuse promiscuously upon the surface is preferable to the American village method of fostering and festering it in cumulative concentration.

As regards the allegation that "the young men at work in the fields were more frequently attacked (by typhoid fever) than the females, who were generally engaged in domestic duties in or about the house," it may be observed: First, that agricultural laborers do not spend all their time in the fields, but sleep in rooms from which, as a class, they carefully exclude all ventilation; second, that, for some unexplained reason, enteric fever seems to have a selective affinity for robust young males. It is an affair of common observation that, under apparently precisely similar conditions, fragile women may resist the infection to which strong men succumb.

Facts, however, are more forcible than words, and I therefore subjoin a few examples of coincidences which have very much the air of causes and consequences. I have excluded instances where water-pollution could be supposed to bear a part, and also those where careful inquiry did not seem to eliminate the possibility of immediate or mediate importation of contagium from a pre-existing case. And let me, at the outset, deprecate the Liebermeisterian criticism that if an adynamic fever

with peculiar temperature-curve, abdominal symptoms, etc., be not directly traceable to a preceding patient, it is not true typhoid, but only something otherwise indistinguishable from it; or that, without evidence of contagion, a pseudo-membranous angina with grave constitutional depression is not genuine diphtheria, though a remarkably good imitation of the real article. Grant only that there are diseases—call them what you will—which closely resemble the regulation nosological types, that people sometimes die of them, and that they are intimately associated with the eating, drinking, or breathing of filth-products, and I shall, for the present, leave the question of diagnosis to be begged by whomsoever cares for it.

I. *Typhoid*.—Large country house with numerous "conveniences." Two "pan closets" on second floor; one in a small windowless hall-apartment, the other in a bath-room adjoining a bed-chamber; basin and bath-wastes led into trap of water-closet; leaden soil-pipe not continued above the line of fixtures, communicating directly with cesspool, and badly corroded at bends of closet-traps. Servants' pan-closet in basement with foul and leaky "retainer"; kitchen and laundry wastes on same horizontal branch, constantly liable to siphonage. Frequent illnesses of minor grade prevailed in this household until the whole plumbing system was reconstructed on a proper plan, since when the inmates have enjoyed excellent health.

II. *Typhoid*.—Small house in village street. Under the cellar runs the ill-covered channel of a former brook, which receives the sewage of several adjoining tenements. The house-refuse is discharged into this foul trench through an open untrapped conduit in the basement.

III. *Typhoid*.—Cottage of better class. No plumbing fixtures except kitchen sink, which discharges untrapped into an obstructed and very foul drain; leaching privy-pit on higher ground than the basement, which, with the foundation walls, is uncemented, affording ingress to ground-atmosphere.

IV. *Diphtheria*.—Elegant mansion, regarded by owner and "practical plumber" as a model of sanitary construction. Soil-pipe extended above roof, but without ventilation at its foot. Materials and workmanship good. On a lateral branch was a down-stairs water-closet into the trap of which the kitchen waste discharged, and into the dip of the running-trap of this horizontal soil-pipe, in the basement, and within a few feet of the furnace, was inserted a servants' hopper-closet without any flushing fixture; excremental matter being, of course, thus retained in the trap a great part of the time, and its decomposition favored by the admixture of hot water from the kitchen. When the water from the boiler was set running, the steam arose freely from this hopper.

V. *Diphtheria*.—Handsome country-seat. Plumbing work recently overhauled and declared perfect by the plumber. Three foul pan-closets, and numerous other "conveniences," all leading to unventilated cesspool. In the bedroom occupied by the patient the "safe-waste" from a stationary basin was carried into the soil-pipe, constituting a direct inlet from the cesspool.

VI. *Diphtheria*.—Presumably "first class" residence. Kitchen and laundry wastes carried from basement into privy vault, which was filled to above the level of the pipes.

VII. *Typhoid?* (two irregular cases).—Cottage in good neighborhood. Bath and basin wastes discharging into trap of foul pan-closet with "putty-joints." Two-inch tin pipe inserted, with leaky slip-joint, into bend of water-closet trap, and carried with several angles to roof; no other ventilation of soil-pipe, which connects with leaching cess-pool. Cellar riddled with rat-burrows (indicating probable connection with some old drain), and air-box of furnace made of loosely jointed boards, so as to convey the cellar-air to upper part of house.

VIII. *Typhoid?* (continued fever). Cottage on high

ground. Offensive pan-closet on bedroom floor. Soil-pipe relieved by angular galvanized vent, but carried without other ventilation or trapping to cesspool on lower ground. Kitchen and laundry wastes untrapped and led to a row of buried barrels which were filled with a most malodorous mess, the water being allowed to soak into the soil as best it might.

IX. *Diphtheria*.—House without plumbing fixtures. Cellar loosely paved with bricks, and saturated with soakage from several privy-vaults on much higher ground and close in the rear; the fecal-smelling semi-liquid filth actually oozing up between the bricks when they were stepped upon.

X. *Diphtheria*.—Cottage alleged by the owner, and innocently believed by the tenant, to be "one of the best-plumbed houses in the county." Pan-closet in a decadent and offensive condition, with untrapped bath waste and insufficiently trapped basin waste led into its seal. Short vent from bend of closet-trap to outside of wall, with orifice closed during winter "to prevent water-pipes from freezing"; soil-pipe thus without ventilation at top or bottom. Butler's pantry-sink connected by tin pipe with earthenware drain, which was badly laid and composed of different sized pipes. Some distance beyond the junction of the soil-pipe and wastes, this drain was tapped by a "ventilating" pipe carried into a chimney flue, with an occasional down-draught. Kitchen waste opening directly into an unventilated cesspool. All lead pipes of poorest quality.

XI. *Diphtheria*.—Country farm-house. No plumbing. Uncemented cellar; living-room in wing built directly upon the earth. Overflowing privy-vault within twenty feet and on higher ground, the soakage and surface-washing from which had permeated the soil around and under the building.

XII. *Diphtheria*.—Large and handsome house. Sanitary arrangements satisfactory to plumber. Pan-closet with insufficient flush. Two-inch tin vent from bend of soil-pipe carried with various angles into cold chimney-flue. Running under the whole length of the basement was an eight-inch earthenware drain, receiving the soil-pipe and the wastes from different fixtures; its large calibre and slight grade precluded proper flushing, and it was thickly coated with refuse and chilled grease. Into its upper end was inserted the overflow from a tightly covered cistern, so that the only ventilation of the entire house-drainage system was through the rain-water leader, close to a "mansard" bedroom window.

XIII. *Typhoid?*—Two small houses of the poorer class, situated on a road at the foot of a steep declivity. No plumbing. Two privy-vaults, a pig-pen, and an indescribably filthy cow-stable just behind and above them, from which the washings were traceable into their cellars.

I could extend the list by scores of illustrations of rural house-defects: soil-pipes disjointed from their outlet drains and discharging their sewage under basement floors; cesspools "backing-up" into kitchen sinks or laundry tubs, or pouring a reflux tide through "overflow" pipes into drinking-water cisterns; ingenious devices of every sort to deprive the gases from pent-up filth of any escape save into the dwelling. And these among the "wealthier residents," whose surroundings are commonly supposed to be above suspicion. As regards the unplumbed poor, their chances of inhaling filth-polluted air or imbibing filth-contaminated water are often enhanced by inadequate cubic space and faulty construction within doors, and ignorant neglect of the very rudiments of hygiene in the environment; their cellars and wells being sunk in soil saturated with putrescent refuse. In the intermediate agricultural or mechanic class similar conditions frequently exist, their potency for evil depending chiefly upon the porous or retentive character of the soil; precautions to exclude the ground atmosphere from cellars or basements are seldom found; cesspools and privy-vaults are close at hand; and it is

a common thing for a couple of adults and two or three children to sleep in a "stuffy" unventilated room with not more than 1,000 or 1,500 cubic feet among them.

From a sanitary point of view it matters little whether the gases from decomposing sewage escape from sodden soil or from a foul sewer; their nature is alike in either case, and the aggregate dose may be even larger in the former instance. But when, and why, and how, they, or any of them, exert their most deleterious influences, are questions which it is impossible to answer in the present state of our knowledge. It is an indisputable fact that people may for a long while be exposed to them without pronounced manifestations of "filth disease,"—although such people, in my experience, are seldom thoroughly well, even if not specifically ill. But sooner or later an apparent qualitative change may take place and an acute zymosis declare itself. I have elsewhere suggested the part that may be borne in this complicated problem by a "personal factor," or temporarily altered individual susceptibility;¹ but it seems necessary also to assume an alteration in the external conditions; and such alteration is explained by many etiologists on the hypothesis of the importation or evolution of specific pathogenic micro-organisms. That certain varieties of schizomyces are associated with some of the acute infections is beyond doubt; that in a few, such "microdemes" are the conveyors,² if not the causes, of the infection seems proven; but it must be remembered that in the diseases chiefly under consideration no characteristic bacteroidal forms have been defined. In typhoid fever, Klebs describes a bacillus where Letzerich finds only micrococci; according to Wood and Formad, the micrococcus of diphtheria is just like that of the ordinary buccal mucus; indeed, nearly all of the acutest infectious diseases are attributed to these ubiquitous micrococci, indistinguishable from each other in most instances, and divided into species solely on the score of their assumed physiological effects. Admitting all that the most ardent advocates of the germ theory can claim for it, there are at least three possible ways in which filth and fungi may be connected:

1. Taking the view of Naegeli and others as regards the mutability of the bacteria, it is conceivable that the common "scavenger" microphytes may acquire pathogenic properties by successive generations of development amid the products of certain decomposing substances. In favor of this conception may be cited the seemingly gradual intensification of "filth-poisoning" in numerous instances; sore throats of a less septic type forerunning outbreaks of diphtheria; diarrhoeal derangements preceding enteric fever; and, farthermore, Koch has found both bacillus-spores and micrococci in surface-soils, the latter organisms preponderating where the earth is subjected to excremental soakage.

2. Or, accepting the specific classification of the schizomycetes, it may be supposed that some pathogenic germs obtain favorable intermediate conditions for their development and multiplication in these products of decomposition; a supposition almost necessary if the specific-germ theory be applied to enteric or choleraic discharges.

3. Finally, if it be conceded that desiccated spores may retain their specific vitality indefinitely, and be air-wafted almost unboundedly, the predisposing action of our filth emanations may be imagined to be cumulative, slowly undermining the individual powers of resistance, or rendering certain cell-groups an easier prey to the intruding organisms in the struggle for existence.

Which of these hypotheses, if either of them, will ultimately prevail, is a question only to be decided by experimental investigations which are beset by a multitude of difficulties and sources of error.

"A NOVEL MODE OF CLEANSING THE VAULT OF THE PHARYNX."

By JOHN O. ROE, M.D.,

ROCHESTER, N. Y.

IN the issue of THE MEDICAL RECORD for April 28, 1883, Dr. G. Fairfax Whitney reported a case which came under his observation in his clinic at the New York Post-Graduate Medical School, in which the patient employed the tip of his tongue for removing lumps of hardened mucus from the upper part and vault of the pharynx.

These cases must be quite rare, or this physiological peculiarity would have been mentioned in medical literature long before this.

Dr. Whiting remarks that his case is, he believes, the only one of the kind reported. As this peculiarity is a rather interesting one, I will add the report of a similar case, which came under my observation about thirteen months ago.

H. W.—, a bookkeeper, aged twenty-five, consulted me April 15, 1882, in regard to a nasal and throat trouble which had annoyed him very much during the previous year. He had had some nasal catarrh for about twelve years, but it was only during the last year of this time that it had become aggravated. It was attended by considerable mucus discharge from the anterior nares, and in the posterior nares and vault of pharynx the mucus became dried down in the form of crusts, which he was in the habit of removing with the tip of his tongue. He also had considerable irritation about the larynx, attended with cough, and a constant tendency to clear the throat by hawking. Expectoration was slight, consisting mainly of tenacious mucus.

He was seldom hoarse, and only when his nasal trouble was aggravated by any cause. His general health was poor, and he had become weak and debilitated.

Examination revealed a chronic rhinitis with some thickening of the inferior turbinated tissue. There was also some adenoid hypertrophy in vault. This he could plainly detect with his tongue, and also several holes or depressions in it which were plainly visible in the rhinoscopic mirror.

As his nostrils were narrowed by thickened turbinated tissue, I could not plainly observe through the nostrils the tip of the tongue when in the vault of the pharynx, as Dr. Whiting could in his case; but my patient would move with his tongue a probe, if inserted through the nostrils to their posterior opening, and if it were pushed back further, he could throw it forward nearly out of the nostrils. By looking into his mouth when he performed this feat, his tongue could be seen to pass up behind the palate, and to bury itself almost out of sight behind the vail.

In this case there was nothing abnormal to be seen about the tongue or fauces. The space between the velum palati and the vertebral column was not unusually large, and the frænum linguæ was well marked, though a little longer and more lax than is usual. His tongue was quite long and rather slender; the only peculiarity to be especially observed was the great voluntary muscular control which he had over its movements, being able to place it in any conceivable position in the mouth, fauces, and naso-pharynx.

ABORTING HORDEOLUM.—Dr. J. P. McGee (*Medical and Surgical Reporter*) claims good results from the following in hordeolum when used within the first six to twelve hours: ℞. Ex. fl. belladonna, gtt. iij.; aquæ pluv. ʒ ij. M. Sig.—A teaspoonful every hour. At the same time calcium sulphide should be given one-eighth or one-tenth grain every hour, for five or six doses, then every three. The belladonna is often sufficient alone.

¹ Trans. Am. Med. Ass'n., 1880.

² In fetal syphilis it is assumed that the spermatozoa may be the carriers of the disease; but no microscopist has yet described a separate species of spermatozoan for such cases.

THE ARSENITE OF BROMINE AND ITS USE IN THE TREATMENT OF DIABETES MELLITUS.¹

By R. H. GILLIFORD, M.D.,

ALLEGHENY, PA.

In the early part of December, 1882, I began some experiments with bromine and arsenious acid, the results of which have, in part, been corroborated by experiments performed at my request by a practical chemist. As I can find no account, in any works on chemistry, of a compound or salt formed by the union of bromine and arsenious acid, I submit my results or views with diffidence, and will welcome either correction or confirmation.

I find that bromine and arsenious acid will unite under certain favoring conditions, in the proportions of two hundred and forty parts by weight of bromine to ninety-nine parts by weight of arsenious acid. When they are perfectly united, or arsenious acid completely dissolved by the bromine, they form an oily liquid, soluble in water and alcohol without any apparent reaction. They unite very slowly, and sometimes seem for many days as if no union was taking place when merely agitated in contact with each other. When united without the addition of water they form a salt which consists of three equivalents of bromine and one equivalent of arsenious acid, and would be represented by AsO_3Br_3 .

When water is added before the bromine is united completely with the arsenious acid, or when bromine and arsenious acid are brought together in the presence of water, there takes place an immediate and rapid reaction with the evolution of considerable heat. Evidently the water is decomposed, and hydrobromic and arsenic acids are formed, and the result is a solution of the two acids with a little free bromine in the excess of water.

The solution used in the appended cases was made by the complete union of the arsenious acid and bromine before the addition of water, and from observation I believe it to be much less irritating to the stomach than a solution of the hydrobromic and arsenic acids.

As I have seen no account of any compound of bromine and arsenious acid in any medical works or journals, I have concluded that I have been the first, in this country at least, to make and prescribe arsenite of bromine.

Dr. Theodore Clemens, of Frankfort, Germany, has been using some compound of bromine and arsenic in the treatment of diabetes, and has reported great benefit from its use.

The medical journals have called his remedy bromide of arsenic, but from the known properties of bromide of arsenic it seems much more probable that the article he uses is either arsenite of bromine, or a solution of the hydrobromic and arsenic acids.

I have made a solution of arsenite of bromine, and used it in a number of cases, and furnished it to several physicians, who have prescribed it and reported to me its effects in the treatment of diabetes mellitus.

While the notes of some cases are incomplete in many important points, yet its use has been followed by the most marked benefit in every case in which it has been prescribed so far.

Some of the cases seem to have made a complete recovery, others seem to be progressing steadily toward a complete recovery. Dr. C. Emmerling, of Penn Avenue, Pittsburg, has treated two cases of diabetes mellitus with my solution.

The first case, a male, aged thirty years, was benefited so much that in two weeks' treatment he had got rid of all the distressing symptoms of the disease: the specific gravity of the urine falling from 1036 to 1029, and the quantity of urine being decreased to less than one-half that

passed at the beginning of the use of the remedy. The patient being of dissipated habits, disappeared from the doctor's observation.

Dr. Emmerling's other patient met with the same marked and immediate improvement following the use of the remedy. He was forty-seven years of age, a saloon-keeper by occupation, a very large man, and a very heavy eater and drinker. The quantity of urine passed was enormous. Dr. Emmerling reports that he seems to be getting well. The specific gravity of the urine has been reduced from 1036 to 1028, and the quantity of urine passed has been reduced to from four to four and one-half pints in twenty-four hours, after one month's treatment.

Dr. A. D. Johnston, of Sedgwick Street, Allegheny, furnishes the following notes of a case treated by him: "Weston Hall, aged nineteen years, laborer in steel works, called March 19, 1883, for treatment, and stated as follows: About January 1, 1883, he was carrying one end of a steel axle, and the man at the other end allowed his end to fall; the jar or shock was so severe as to unfit him for work for several days. Shortly after the accident he noticed an increase in the flow of his urine. The flow increased until, March 20th, he was passing three gallons of urine in twenty-four hours, of acid reaction and specific gravity of 1035. His thirst was constant. He could not eat enough to satisfy the cravings of hunger, and is very much emaciated and very weak. Tests for grape sugar in the urine show not less than twenty-five grains of sugar to the fluid ounce, estimated by the fermentation test.

"March 22d.—A solution of arsenite of bromine was procured from Dr. Gilliford, and two drops ordered to be taken four times daily.

"March 25th.—Improvement marked as regards the quantity of urine passed; thirst not nearly so excessive; feels better after eating; feels stronger; spasms of the calves of the legs disappearing; specific gravity of the urine 1030; can lie until nearly morning, whereas formerly he was compelled to rise at least three times during the night to void urine. Dose increased to four drops four times a day.

"March 29th.—The patient is able to lie all night without rising to urinate. The improvement in strength and general health very marked.

"April 17th.—The patient thinks himself well. His gain in flesh is very noticeable. Urine passed in twenty-four hours, eighty fluid ounces, specific gravity 1020, acid reaction. Fehling's test shows no sugar in the urine. The patient leaves for Clarion County in a few days, to go to work, promising to write weekly and keep a record of the amount of urine passed."

Dr. J. B. Johnston, of 25 Pennsylvania Avenue, Allegheny, Pa., furnishes the following notes: "On April 16, 1883, I was called to see a boy, aged sixteen years and five months. I found him very much emaciated, but complaining of nothing in particular, only that his thirst was insatiable and he was *ravenously* hungry, as he said. He said his fauces and throat were very dry and parched. I examined his tongue and found it red and fissured. From the symptoms I concluded he had diabetes; he was passing from a gallon to a gallon and one-half in twenty-four hours of limpid urine. I immediately made the tests for saccharine urine, and found it to contain sugar in very decided quantity. Moore's, Tromer's, and the yeast test, all verifying each other, I put him on the usual treatment of cutting off the non-nitrogenous supplies, and fed him mostly upon meats, animal broths, vegetable soups, fresh fish, etc., including cabbage and turnips. The specific gravity, when I first saw him, was 1038. I found it to vary in density from 1035 to 1040. I tried the different modes of treatment usually resorted to, but must say I found little or no improvement in the case. I found the best results in the first part of the treatment from tinct. ferri mur., given in fifteen-drop doses half an hour after meals, in a wineglassful of water.

¹ Read before a meeting of the Allegheny County Medical Society, at Pittsburg, Pa., May 15, 1883.

During the times he was taking the *iron* the thirst was not so distressing nor was the appetite so voracious, but the urine was *nearly* if not *quite* as copious, and the specific gravity remained *high*.

During the time the *iron* was being given there was passed on April 27th, 132 ounces of urine; April 28th, 130 ounces; April 29th, 129 ounces; April 30th, 127 ounces; May 1st, 131 ounces; May 2d, 129 ounces; May 3d, 126 ounces. During this time the specific gravity varied a little, from 1036 to 1038. On May 4th I began giving four drops of arsenite of bromine (my attention having been called to it by Dr. R. H. Gilliford) largely diluted with water, half an hour after each meal. On the 5th the quantity of urine, to my surprise, had fallen to 110½ fluid ounces. On the 6th to 100 ounces, with specific gravity of 1034. On the 7th I again examined the density of the urine and found it 1032, with a still decreased quantity, 98 ounces. May 8th, I did not take the specific gravity, but found 94 ounces of urine. Patient is sleeping well at night and says he does not need to get up so often to urinate. May 9th, specific gravity 1032, and 94 ounces of urine, same as on the 8th, but he confessed to indiscretions in his diet. May 10th, specific gravity 1031, with 92 ounces of urine. Thinking the dose of the arsenite might be safely increased, I began on the 9th to give five drops instead of four. May 11th, specific gravity 1030, with 89 ounces. May 12th, specific gravity 1030, with 87 ounces. May 13th, I did not take the specific gravity nor quantity. May 14th, examined both quantity and quality of urine. Specific gravity has fallen to 1029, and the quantity is 85 ounces. The symptoms of the patient are not by any means so urgent as in the beginning of the treatment. *Thirst diminished, appetite less craving*, diminished quantity of urine from 132 ounces to 85 ounces, specific gravity diminished from 1038 to 1029. There is one thing to be observed, that there has been a *constant decrease* in the quantity and specific gravity of the urine, though it has not been regular; but when we see that the *remedy* has been in use only since May 4th (ten days), we cannot but look upon the case with *much* hope. What the subsequent condition of the patient may be cannot yet be known.

A CASE OF CENTRAL SCOTOMA WITH DERANGEMENT OF COLOR PERCEPTION

CURED BY THE HYPODERMIC USE OF NITRATE OF STRYCHNIA.

By DAVID WEBSTER, M.D.,

PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC.

THE patient, a married lady, twenty-seven years of age, consulted Dr. C. R. Agnew and myself on March 21, 1876. She said she had had no trouble with her eyes since childhood until suddenly, one morning about a week previously, she discovered that she was nearly blind in her right eye. There was no pain in or about the eye, and she was led to test the vision of each eye separately only by noticing some peculiarity in her vision. She immediately consulted her family physician, Dr. Ely, of Newburg, who, being at a loss to account for the defect in sight, referred her to us for examination and advice.

Upon applying the usual tests we found that the left eye had vision $\frac{3}{20}$, and seemed to be normal. In the right visual field was a large central scotoma, which gradually shaded off into the periphery of the field without any distinct or well-marked boundary. The patient managed to read $\frac{3}{20}$ with the right eye by dodging her head about and catching the letters eccentrically. Tested with the colored worsteds, she called blue a "dark gray," or "black." Green she called "black," or a "dark shade of brown." She recognized red. She called yellow "brown," but saw that it was yellow when placed in the extreme nasal portion of the field.

She was confined in June, 1875, and it was remarked

that her eyes were unusually strong. She would not have the room darkened, but abstained from reading for a long time, at least six weeks.

On the Sunday preceding the Wednesday in the morning of which she discovered impaired vision, she was "overcome by heat" in church, went out, and was seized with a spasm of the throat. For years her friends have remarked that she was in the habit of keeping her right eye closed when out riding or walking.

Ophthalmoscopic examination showed no gross lesion, but there was a faint opacity of the posterior capsule of the right crystalline lens. The optic disk seemed a little too pale, and the retinal arteries were apparently slightly reduced in size.

She returned to Dr. Ely with a letter recommending the daily hypodermic use of nitrate of strychnia, beginning with a small dose, and cautiously increasing the quantity day by day until the physiological effects of the drug should be reached.

She made two subsequent visits to the office. On April 5th her sight had risen to $\frac{3}{20}$ (+), having increased more than seven hundred per centum in fifteen days. On April 22d it was noted that the dose of nitrate of strychnia injected had reached one-seventh of a grain without producing any of the unpleasant constitutional effects of the remedy.

On April 30, 1883, her husband called upon us and concluded the history. He said that the hypodermic injections of strychnia were continued for a short time after her last visit, and resulted in perfect recovery of vision, which remained good until her death, which occurred in 1880, and which was caused by an attack of cerebro-spinal meningitis.

OPIUM ADDICTION AMONG MEDICAL MEN.

By J. B. MATTISON, M.D.,

BROOKLYN, N. Y.

It was the writer's pleasure, some time ago, to dismiss from his professional care, within about a week of each other, six medical gentlemen, all recovered after addiction to morphia, hypodermically, varying from eight months to ten years.

This somewhat unusual occurrence, with the fact that the majority of his patients have been, are, and probably will be, members of the profession, and the statement elsewhere made that physicians form a large proportion of opium habitués in general, and the great majority of any professional class, make pertinent the title of this paper and warrant his inviting your attention for a brief time to a topic in which perchance some of you may have a personal and painful interest.

A recent Austrian author writes: "Quite an incredible number of our colleagues have fallen victims to it, and many have only just escaped. If medical men are charged, and it is to be feared, justly, with the propagation of this disease, owing to their carelessly, or for mere convenience sake, leaving morphia and a subcutaneous syringe with the patient, it may be regarded as their punishment that the demon morphinism finds among them his favorite victims."

A Prussian writer who, in 1877, gave the profession a valuable monograph on morphia addiction, cited sixteen cases under his care, of which medical men formed more than one-third, and a much larger proportion compared with any professional class.

The records of the Inebriates' Home, at Fort Hamilton, although that institution is mainly devoted to the treatment of alcoholic habitués, show a majority of the profession among those who have sought relief from the ravages of opium.

We have been informed, on the asserted authority of a resident physician, that, in a certain New England city, containing upward of one hundred medical men, between thirty and forty are addicted to some form of opium.

Much surprise has often been expressed, and the reason asked why so many physicians apply for, or are in need of, relief. So far as concerns the first query, and as having a personal reference, we have always deemed it due to the fact that our professional efforts being directed specially to this work, and a knowledge of this coming directly to the fraternity through the medium of the medical press, those who desired our aid availed themselves of the proffered service.

Another reason may be that the peculiar secretive character of this disorder, the fear of publicity, induces the most of non-professional victims to place themselves under the care of charlatans, who find in this especial quality a fertile field which they make haste to till to their profit, and, very often, their patients' loss; while medical men, on the contrary, not so likely to be duped by the specious promises of these pretenders, are less frequently beguiled by their blandishments, but extending their confidence to those whose skill and experience warrant, secure the aid which scientific treatment can now surely afford. As to why so many opium habitués are recruited from the ranks of our profession, it may be said that the physician's calling involving, as it often does, especial inroads on his mental and physical well-being, exposes him more than any other to the various influences which stand as factors in the etiology of this disease.

Then, again, addiction, hypodermically, is likely to prevail largely in medical circles, inasmuch as the very nature of this method requires a more or less intimate knowledge of morphia and the hypodermic syringe, which the average layman does not possess.

Then, too, may not this very knowledge and the frequent employment of this potent agent for evil as well as good which the modern practice of medicine involves, disarm fear of its ill-effects, and make easy the occasional taking, which so easily and so soon forges the fetters of confirmed addiction?

Obersteiner's remark as to the retributive justice of the morphia Nemesis to those who, as he asserts, directly assist in enlarging the ranks of the opium devotees, suggests a topic worthy of no little reflection.

In reviewing the causes of opium addiction among medical men, we find that in them, as in others, some form of neurotic disorder, involving, as has been truly said by your coming president, "a physical necessity," leads the list; and, so far as our experience goes, the most frequent has been that "opprobrium of medical art"—as Flint styles it—periodical headache. Any form, however, of persistently painful disturbance involves this risk, and, apropos of this point, the opinion of a medical gentleman—who, some years ago, was under our care, and who afterward gave to the profession a most graphic recital of his experience—may be of interest. "I proclaim it as my sincere belief that any physician afflicted with neurotic disease of marked severity, and who has in his possession a hypodermic syringe and Magendie's solution, is bound to become, sooner or later, if he tampers at all with the potent and fascinating alleviative, an opium habitué.

"The first dose is taken, and mark the transformation! This overmastering palliative creates such a confident, serene, and devil-may-care assurance that one does not for once think of the final result. The sweetness of such harmony can never give way to monotony. Volition is suspended. You may not think of it when the pain for which it was taken subsides. But when distress supervenes, you go at once for the only balm that abounds in Gilead, and every additional dose is but another thread, however invisible, of which the web is made that binds us fast as fate."

Another special factor is the peculiar power that opium possesses to give strength, bring sleep, and relieve portendings incident to the anxious hours, the weary days, and wakeful nights, such as the experience of every busy practitioner so often involves. Again and again has this

been told us, and, pre-eminently true is it when—once under the opiate spell—a self-effort is made to escape. Scarcely a physician presents himself for our care who does not assert that, time after time, he has made an attempt in this direction, only to find that the demands of his calling proved fatal to his success.

Still another cause is the spirit of inquisitive research which occasionally permits a professional man to allow his zeal in the pursuit of knowledge to outrun his discretion.

Incidentally we may note the assertion—doubtless true—that the glamour of De Quincey's writings has proved fatally attractive to more than one, and Obersteiner relates this instance: "A young medical man gave the following account of his own case. While he was attending the hospital a patient was dismissed, suffering from carcinoma of the stomach, and who had been for a long time treated with subcutaneous injections of morphia. Next day the patient returned in a state of great excitement, and piteously begged for an injection, as otherwise he must die. This occurred in 1869, at a time when chronic morphinism and its phenomena were less known than now. As the physician was inclined to believe that the patient was romancing, he tried the experiment on himself to ascertain what the effects were. The result was that he formed the habit of morphinism, and never could overcome it."

He also cites another, of a medical man, aged thirty-two, who gave as one reason for his addiction that, "being assistant at the Physiological laboratory, he saw in himself an interesting subject of experiment."

A somewhat similar case has fallen under our own observation. Dr. A—, aged twenty-seven, was attacked with facial neuralgia so severe as to compel his taking one-fourth of a grain of morphia hypodermically, at bedtime, to secure ease and sleep. This amount was increased to one-half a grain per diem during the following month, when, the neurotic disorder having subsided, the opiate was abandoned, with little or no inconvenience. Some time after this, a gentleman addicted to the use of morphia placed himself under his care. Then Dr. A—, as he asserts, without the least desire for opium, but solely from a wish to discover, if possible, some antidotal drug to aid him in the cure of his patient, began experimenting on himself with hypodermic morphia, with the result of falling a victim to its seductive influence; and yet, though he failed to make the wished-for discovery, managed the case of his friend so well that success crowned his effort, while he, despite every endeavor, was unable to extricate himself from the pit into which he had unwittingly fallen, and was compelled to seek aid for his relief. Unlike Obersteiner's patient, he made a very gratifying recovery, and is to-day well.

The subtly ensnaring power of opium is simply incredible to one who has not had personal observation or experience. One of the finest specimens of physical manhood we ever saw, a physician, who survived the horrors of Salisbury prison, when the death-rate averaged eighty per cent., fell a victim to morphia after only one month's hypodermic using. Happily, he recovered, took the lecture platform, and told of the bondage from which he escaped.

It may seem to some of you like an alarmist's opinion, yet we have no hesitation in expressing our belief that any physician using morphia, daily or oftener—especially hypodermically—for four weeks, incurs great risk of becoming an habitué; indeed, we think a still shorter usage might, with some, prove a snare.

Having thus spoken of this peculiar peril, it might seem fitting to suggest that which would tend to lessen or avert it; but a proper limit to this paper precludes.

Of the gentlemen who honored us with their confidence, some details may be of interest.

Dr. B—, aged thirty-seven, six years' addiction. Cause, asthma; on admission was taking eight grains per diem, and for several months he had also taken daily

ninety grains of chloral. The latter was at once withdrawn, and to make amends for this sudden removal, his daily taking of morphia was increased to twelve grains, so that the chloral withdrawal caused no discomfort whatever, except slight mental depression the following day. Sedative treatment was begun and the morphia withdrawn in six days, with so little disturbance that the patient was up and about during the entire time, and after the final habitual hypodermic of one-third of a grain, attended a theatrical performance. Moderate restlessness followed, but the reflex irritation in general was slight, the most prominent being insomnia, which was unusually marked and persistent, requiring soporifics for several weeks. Improvement, meantime, in other directions was decided, and his case was dismissed, recovered, on the forty-seventh day of his treatment, sleep having been free from hypnotic the previous week.

A special point in the prognosis of this case, referred to the return of his asthmatic trouble when the habitual narcotic was abandoned. As a fact, much to our pleasure and surprise, not a single paroxysm—save one of less than half-hour duration, and so mild as to cause but little discomfort—occurred up to the time of his leaving, nor has there been any to date. This, to us, is an interesting and important therapeutic feature, as suggesting how much influence a prolonged narcotic condition may have had in obliterating a neurotic status, the outcome of which was his dyspnoic disorder.

It is known that in the treatment of obstinate sciatica, Trousseau advocated opium in full and increasing doses up to the point of entire relief from pain, and the maintaining this semi-narcotized condition for weeks or months, if required; and we have been told of a case thus treated with success in the person of a near relative of a well-known New York professor of therapeutics.

Stevenson, of London, himself a victim of asthma, and who has given us the latest work on the subject, asserts, after long and varied personal experience, morphia, hypodermically, to be the most effective agent for relief. Of course its use entails the risk of addiction, but in otherwise unyielding cases of this distressing disorder it might be wise to counsel the taking that risk.

Dr. C—, aged thirty-eight; cause, chronic diarrhoea; duration, ten years; amount, maximum, thirty grains per diem; on admission, fourteen. Special treatment and hypodermics abandoned at end of eight days. Effects were restlessness, insomnia, aching in lower limbs, and occasional abdominal pain—none of which were severe and all relieved by appropriate treatment. Natural sleep returned in less than a week, patient's improvement was prompt and steady, save one interruption from an attack of indigestion, and he was dismissed on the twenty-sixth day of his treatment.

Fuller details of this case may be found in the *New England Medical Monthly* for June, illustrative of a paper on "Neurotic Pyrexia, with Especial Reference to Opium Addiction."

Dr. D—, aged twenty-eight; three years' addiction; three to five grains daily; cause, sciatica. Special treatment secured; desired sedation and hypodermic withdrawal in five days. The sequelae were restlessness, relieved by hot baths; aching below knees, removed by strong faradic current; and debility with insomnia, requiring tonics and soporifics, the former throughout treatment, the latter less than one week. Patient recovered rapidly, and was dismissed on the twenty-second day of his treatment.

Dr. E—, aged forty-eight; eight months' addiction. Morphia had been increased rapidly to sixteen grains daily, but on admission was reduced to six. Sedative régime for five days, when syringe was discarded. Results: restlessness, debility, insomnia, and lumbar pain. For the first and last symptoms, hot baths, local and general, proved promptly effective. Reflex disturbance soon subsided, and patient left on the eighteenth day. Sleep and appetite normal, but strength be-

low par. Decided improvement followed a southern tour of a fortnight, and, on returning, his general condition was noted as fairly good.

Dr. F—, aged forty-six; addiction, with intervals, three years; extent, ten to twelve grains daily; cause, periodical headache. This patient's story, written by himself, formed a narrative of so much interest and importance as proving many of the points in this paper, that we secured his consent, and made it the subject of a paper published in the *New York Medical Journal*, 1883. His hypodermics were discontinued in five days, with results similar to case of Dr. E—, though the insomnia was more protracted, yet he put in an appearance at every meal, and did not lose a single entire night's sleep. He was dismissed on the twenty-eighth day of his treatment, and, in company with Dr. D—, sailed for Bermuda. Improvement continued. After returning he gave himself several weeks' longer vacation, then resumed his profession, and is now doing well.

Dr. G—, aged forty-seven; addiction, ten years; extent, six grains per diem; cause, toothache. An attempt was made to treat him at home, but, after abstaining forty-eight hours, he became violent, smashing furniture, and the opiate was resumed. He then came under our care, and was allowed sufficient morphia to give him comfort, and this continued five days, during which special treatment was employed. Sedative effect desired, secured, and the habitual opiate abandoned. The resultant irritation was mild, the most so of any of the six cases. Restlessness, depression, debility, and insomnia, but none of these marked, and, like Drs. D— and F—, he was able to do dietetic duty daily, and, each night, secure some hours' sleep. Improvement was progressive, and he was dismissed on the twenty-seventh day of his treatment.

To summarize: average addiction, five years; average length of treatment, twenty-eight days.

Remedial measures involved bromide of sodium, hot baths, electricity, both galvanic and faradic current, belladonna, strychnia, hyoseyama, quinia, chloral, coca, cannabis indica, Jamaica dogwood, varied tonics, full feeding, and cheerful surroundings, for details of which see paper, "Clinical Notes on Opium Addiction," *Cincinnati Lancet and Clinic*, March 3, 1883, reprints of which may be had on application.

All recovered. Repeated experience warrants the assertion that every case of opium addiction, free from organic disease, and in which there is an earnest desire to recover—be the extent and duration what it may—admits of prompt and positive relief.

THE SUPERIOR VALUE OF THE BROMIDE OF SODIUM.—Dr. Field (*Boston Medical and Surgical Journal*, May 10, 1883) believes that the superiority of the sodic bromide over its potassic congener is insufficiently recognized by the profession. From a physiological study of the subject he feels justified in stating the following propositions: 1. The bromide of sodium, because it is a sodic compound, should be more congenial, less disturbing, to the fluids and solids of the body than its potassic congener. 2. The sodium salt, in extended use, should be less depressing to the heart, all potassic salts, after a time, tending to produce cardiac depression. 3. The sodic bromide is less offensive to the taste, much less irritating to the stomach. 4. The bromide of sodium should have equal, if not superior, general therapeutic power with the bromide of potassium, since while the former has a bromine per cent. of 78, the latter has but 66. Clinical experience, moreover, has brought him to the following conclusions: 1. The bromide of sodium has equal therapeutic power, throughout the entire range of medication, with that of the bromide of potassium. 2. Not only this, but the bromide of sodium has superior therapeutic value, both from the greater mildness of its physiological impression and because of additional therapeutic applications which, were we confined to the potassic salt, would be inconvenient, if not impossible.

Progress of Medical Science.

TREATMENT OF FLOATING KIDNEY BY FIXATION.—

Dr. David Newman, of Glasgow, has recently performed the operation of nephroraphy. The operation was done in the following manner: The kidney was exposed by a vertical incision in the right loin, immediately external to the outer edge of the quadratus lumborum, and extending from the lowermost rib to the crest of the ilium; the capsule of the kidney was opened, and stitched to the edges of the wound; and two catgut sutures were passed through the cortex of the kidney, the muscles, fascia, and skin, and secured externally by buttons. The patient suffered from severe symptoms, and was treated for several years without success. Since the operation the symptoms have entirely disappeared, and she has now almost recovered from the effects of the operation, which was performed three weeks ago.—*British Medical Journal*, April 28, 1883.

DIPHTHERIA AND NEPHRITIS.—We are still in want of observations which shall throw light on the nature of the renal changes associated with diphtheria. The profession is familiar with the doctrine of the infective nature of the nephritic alteration. It is philosophical to bear in mind that albuminuria, so often attendant on cases of diphtheria, may not necessarily be due to actual disease of the kidneys. The manifold antecedents or causes of albuminuria may still come into play, even though the body be the subject of diphtheria. The presence of one cause, however probable its action may be, does not preclude the possibility of a less striking factor being the real agent in any particular instance. We are led to make the foregoing remarks, because Dr. Fürbringer has been unable to detect the micrococci which other observers have demonstrated in the urine and kidneys of cases of diphtheria. We are far from asserting a full belief in the view that diphtheritic nephritis is even generally a bacterial disease. On the contrary, the notion that the primary diphtheritic disease is due to micrococci requires more convincing evidence than has at present been adduced. Dr. Fürbringer has investigated the clinical history and morbid anatomy of diphtheritic nephritis with much industry. He comes to the conclusion that the renal changes may conveniently be arranged under three divisions, according to the degree of anatomical change. The earlier stages are characterized by comparatively slight changes in the epithelium of the cortical region, not unlike "cloudy swelling;" next the cellular degeneration becomes more decided and more widely spread; and there are some alterations in the interstitial tissues, but no vascular lesions. The final degree is comparable with that of the intensely congested kidneys sometimes seen in connection with nephritis after scarlet fever.—*London Lancet*, March 31, 1883.

MERCURIAL DECALCIFICATION.—A remarkable effect of acute poisoning by mercury, in the form of corrosive sublimate, was discovered by Salkowski, and has been confirmed by Prévost and Frutiger, of Geneva, in a very interesting investigation. The effect is the deposition of calcareous salts in the cortical substance of the kidney. The deposits of lime-salts may easily be confounded with deposits of fat. The process commences in the straight tubules, and afterward involves the tubuli Contorti, and is sometimes so great that the kidneys appear as if petrified. The effect is most marked in the rodents, but may also be observed in the cat, and likewise, although with more difficulty, in the dog, and it is apparently of the same nature in all animals. It is very remarkable that this change is not, as might be expected, most marked when the poisoning is most chronic. It is greatest when the doses of the poison are such as to cause death in three or four days, and are too small to kill within twenty-four hours. The Swiss investiga-

tors have made a very important discovery as to the process by which this remarkable effect is produced. They find that the calcification of the kidneys is accompanied by, or rather accompanies, a removal of lime-salts from the bones which, in the case of rabbits, is sufficient to render the epiphyses of the long bones movable on the shafts. In order to estimate the actual amount of decalcification, a series of comparative analyses were made, the tibia being the bone chosen. The loss of lime was found to be usually from two to four per cent., and sometimes to amount even to eight or ten per cent. The change in the bones was always inversely proportioned to the change in the kidney. To obtain even more precise results, the leg of one animal was amputated before the commencement of the experiments, so that the normal proportion of lime-salts might be accurately compared with that present after the action of the corrosive sublimate. But the result of this experiment was the demonstration of a very interesting fact in relation to the processes of calcification and decalcification in the system. It was found that when the animal had recovered perfectly from the effect of the amputation, no mercury having been given, there was an increase in the amount of lime in the opposite tibia. Even after intoxication by mercury, it was found that there was still an excess of lime present, showing that the augmentation due to the amputation of the other leg was more than enough to compensate for the loss produced by the mercury. The peculiar effect of the corrosive sublimate cannot be attributed to impairment of the general nutrition, since in starving animals, which had lost eight hundred grammes of body weight, the proportion of the mineral constituent of the bone was positively increased instead of being diminished. The rapid decalcification of the bone seems to afford an adequate explanation of the accumulation of lime-salts in the kidneys, arrested in the process of elimination by these organs.—*London Lancet*, April 14, 1883.

MODERN THEORIES AND TREATMENT OF PHTHISIS.—

Under the above heading Dr. Pollock has just completed a practical review of a subject which is at present engaging universal attention, even of a non-medical character. This series constitutes the Croonian lectures for this year. He concludes his remarks in the following words (*London Lancet*, April 28, 1883): "No parasitic theory can lessen the importance of the use of tonics and cod-liver oil. Supposing we possessed a local remedy of sufficient power to ensure the destruction of such bacilli as are met with in the secretions, their rapid reproduction would soon overtake our treatment. I fear that in this direction we may have much empiricism and many disappointments.

"Finally, to sum up the brief review which we have been able to make of these new doctrines, it would appear that while some facts, such as the presence of bacilli in all cases of phthisis and their absence in other affections of the lungs and air-passages, are fully proved, there are some assertions of those who hold that such appearances in the lungs and its secretions are the proximate and invariable cause of the disease, which we must for the present hold to be *sub judice*. Among these doubtful theories are those which concern the production of the parasites. Whether they be endogenous or introduced from without, whether they may not find their birth in certain blood-changes which are the outcome of pyrexial action in the system, or whether they are the product of a like morbid condition in other animal bodies, and from them introduced into other organisms by contact or infection, must remain for the investigation of later pathology. We may safely relegate these interesting questions to the ardent students who are now everywhere carrying on new observations. And for ourselves, knowing well that all pathology is progressive, and that we see but a portion of truth at any time, be content to await the result."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 9, 1883.

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE agitation over the subject of medical conduct has at least had this result: it has awakened a special interest in the American Medical Association. The attendance at its session just adjourned, of which we present a full telegraphic account, was larger than ever before, if we except the meeting in this city three years ago.

We are glad to be able to say that the quality of the addresses and papers was, if not very high, on the whole distinctly better than has usually been the case. To this commendation we must make some exception. Papers which had been read before other associations were allowed to be presented to the sections as original, thus openly violating a long-standing rule of the Association.

The vote to establish a weekly medical journal, under the able and experienced editorship of Dr. N. S. Davis, will be received with pleasure by the profession, and we shall welcome another competitor in the higher ranks of journalism. It appears to us, however, that in the details of management of the proposed enterprise there is a serious misconception of its real pecuniary needs.

The election of Dr. Austin Flint, Sr., to the Presidency will be understood as an endorsement of his position upon the question of medical ethics. It would have been more gratifying if the position had come, as it justly might, as the recognition of his character and attainments.

The action of the Judicial Council in compelling all delegates to sign a preliminary pledge was hardly such as became a dignified medical body. But it prevented the chance for the expression of any opinions different from those of the judicial council which so proudly assumed the responsibility of dictating a course for the members. The profession of the country will hardly be satisfied to have its opinions and conduct thus fixed by a few doctors who call themselves a "Judicial Council." This act of the Association was telegraphed throughout the country and everywhere received the condemnation of the press. We do not hesitate to say that the profession of America, by reason of the policy thus adopted, stands lower to-day in public esteem than it did before.

We have been among those who in the past have criticised the American Medical Association. We have done so because a candid judgment upon its work left no other choice. It has been a shifting, purposeless, illy-

organized monster, with a floating membership of (speaking biologically) undifferentiated medical protoplasm. The meeting just past has done much to give it more coherence and purpose.

VACCINATING IMMIGRANT BABIES.

It is not surprising that the sanitary enthusiasm of the present day should at times exhibit some imperfections in its practical outcome.

It appears from the evidence of several authorities that the compulsory vaccination of infants while on board the immigrant steamers, as at present conducted, is not unattended with danger. Upon the steamship *Leerdam*, of the Netherlands, which arrived here last month with eight hundred steerage passengers, there were, it is said, three deaths, and a number of cases of severe illness among vaccinated infants.

A medical man connected with this line remarked that "to vaccinate children, no matter how pure the virus may be, is always followed by fever and inflammation, more or less; but there is not much danger when the child is quietly at home and nursed by a mother who is able to take good care of it; but on board a steamship, packed with hundreds of human beings, the mothers often very sick themselves, food, air, and water altogether different from what these children are used to, some also teething, or being unwell from many other causes in consequence of a sea-voyage, is certainly not the right time and place for vaccination; and his opinion is that this regulation requires immediate review."

This opinion is expressed by several others. A Dutch clergyman, Mr. A. H. Bechthold, has particularly called attention to the matter in a letter to the *Evening Post*.

It is suggested that certificates of vaccination be required by the ship's officers before the passengers are received.

There is no doubt that something ought to be done. We should, however, be very much inclined to investigate the steamship companies first. It is very well known that many of them are not at all particular as to the quality of the virus bought, provided it is cheap. It is strongly hinted also that the medical attendance is often on a par with the virus; and finally, the companies ought not to carry passengers under unhygienic conditions.

With pure, fresh virus, intelligent medical skill, and authority to discriminate as to vaccinating the sick, we believe that few accidents, certainly no fatal ones, can occur.

THE VALUE OF CEREBRAL THERMOMETRY IN DISEASES OF THE BRAIN.

DR. J. T. ESKRIDGE, in a very elaborate report of a case of tubercular cerebro-spinal meningitis, read before the Philadelphia College of Physicians, calls attention among other things to the possible value of cerebral thermometry in brain diseases. He states that the surface temperatures of the head and of the upper posterior cervical region were registered in the case reported on ninety-seven different occasions, during which four hundred and eleven surface temperature observations were made on these parts. The cerebral temperatures exceeded the axillary forty-six times; that of the axilla was higher than

the head temperatures forty-seven times; and the temperatures of the head and axilla were equal four times.

Once the temperatures in the axilla and over the upper cervical region were equal; four times the temperature of the latter region fell below that of the axilla, varying from $.1^{\circ}$ to 1° ; twenty-four times the heat of the upper cervical region exceeded that of the axilla, it having been on one occasion as much as 3.4° above it. The temperature in the upper cervical region was usually greater than that of the head, it having been higher nineteen times out of twenty-nine.

The lowest head temperature found was 95.8° , the axillary heat at that time being 97.8° . The highest head temperature registered was 103.5° , the axillary being 104° . The lowest axillary temperature recorded was 93.8° , the cerebral temperature, at the same time, standing at 98° . The highest temperature found in the axilla, at the time of registering the head temperatures, was 104° , the surface thermometer on the head at the same time rose to 103.5° . Once the head temperature was 4.2° greater than the axillary, but the heat of the axilla never exceeded that of the head more than 2° .

As a result of the thermometrical studies in this and other cases Dr. Eskridge concludes that: 1. The right or left side of the head may, in turn, be the warmest in health. 2. When surface thermometers are used to register the cerebral temperature in disease, the normal averages should be taken to be 1° to 1.5° higher than those ordinarily given. 3. The head temperature in disease of the brain may equal or exceed the heat of the axilla for a length of time. 4. In cerebral lesions the temperature of the head is not marked by those sudden variations manifested by the axillary temperature in these cases. 5. Variations of head temperature in diseases of the brain take place comparatively slowly. The tendency of the heat of the head to remain permanently above the normal, while that of the axilla is normal or several degrees below, is the strongest evidence of organic disease. 6. The thermometer and the microscope in the case reported agreed in locating the greatest inflammatory trouble in the upper cervical portion of the cord. 7. Brain lesions attended by congestion or inflammation have a higher local temperature than suppuration going on within the cranial cavity.

Dr. Eskridge thinks that for purposes of study and comparison we should assume that the average temperature of the anterior, middle, and posterior surfaces of the brain is 95.36° F., 94.1° F., and 93.56° F., respectively.

We have before stated in commenting upon the subject of cerebral thermometry that the relation between the temperature of the scalp and of the brain beneath was, within certain very large limits, a physiological, not a physical one. The mutual changes in temperature are generally due to the intervention of the nervous system. It is known that irritations of nerves of one part of the body will affect reflexly the temperature of other parts. Variations in cranial temperatures, therefore, may be due to changes in the brain beneath, or to irritations in other parts of the body. Hence cerebral thermometry ordinarily affords us but small help in diagnosis. When, however, the brain or its membranes are organically affected the thermometrical variations may be of value. This seems to be the teaching of Dr. Eskridge's case.

THE MEETING OF THE AMERICAN SURGICAL SOCIETY.

We publish elsewhere a report of the fourth annual meeting of the American Surgical Association. There were about forty gentlemen present and about a dozen papers were read, several of them being of the nature of case reports.

We fear that even the utmost stretch of charity will not allow that the meeting was a remarkable one or at all representative of American surgery. Surgical science has reached a high eminence in America, and an association aiming to represent it must show itself awake and progressive. It must present original work, not clinical records at its annual meeting.

We are glad to say, for all this, that several of the papers showed careful labor and were extremely creditable to the Society.

The resolution asking the individual members if they had consulted with homœopaths, and if so, demanding their resignation, concluded, we will not say fitly, the proceedings of the session.

THE PROGRESS OF SURGERY IN THE GREAT NORTH-WEST.

It is a satisfaction to feel that the art of surgery keeps pace with the star of empire on its westward way. We are particularly pleased to observe that the art and the star aforesaid hover so conspicuously around Minneapolis, Minnesota, as evidenced by the columns of the local daily newspapers. One instance of the stupendous strides in surgical science which the great West is making has been recently given to the world by the *Minneapolis Tribune* of May 10th: "Drs. C—— and K—— accomplished a nice piece of work yesterday when they straightened the club feet of an eight-months-old child of Mr. Peltier, on Eighth Avenue north. It is said to have been the only operation in this city where badly clubbed and distorted feet have been straightened." We are informed that since the 10th the child has been doing well.

The operation in question seems to be the culmination of a long series of appalling operations that have been chronicled by the daily press. Dr. X——, says the *Tribune*, has with great boldness opened an immense and painful felon on the hand of an esteemed citizen. Dr. Y—— has amputated three fingers at one sitting, this being the second time so serious and delicate a test of surgical skill has been exhibited in the Northwest, etc., etc.

We are informed that it is a matter of frequent occurrence for some physicians in the Northwest, in regular standing, subscribers to the Code of Ethics of the American Medical Association, to get a free advertisement by letting their brilliant exploits in surgery be published in the newspapers. We trust we may be permitted to inform them that such conduct is not becoming physicians or gentlemen.

A FATAL BLUNDER.—There is considerable excitement in St. Louis over the poisoning of three persons at the City Hospital, two of the cases being fatal. The physician going the rounds administered to them a dose in which the principal ingredient was supposed to be Epsom salts, but which really was hydrate of chloral.

News of the Week.

TWO EPIDEMICS OF MEASLES.—Dr. H. G. V. de Hart, Health Officer of Pleasantville, Westchester County, has declared measles to be epidemic in that town, and all schools have been closed, including private schools and Sunday-schools. Up to yesterday eighty-one cases had been reported. Two patients have died. Nearly every family has been visited. The town is so closely quarantined that children are not allowed to leave it.

The town of Burgholtz, near Lockport, N. Y., is much excited by an epidemic of malignant German measles and scarlet fever. Over sixty cases have developed among the children of the inhabitants, who are mostly Germans. Four schools have already been closed. The disease was brought here about six weeks ago by Prussian emigrants. The Board of Health find their efforts totally inadequate to stay the spread of the disease, and are in great straits.

DR. WILLIAM J. MORTON has resigned from the Chair of Diseases of the Mind and Nervous System in the New York Post-Graduate Medical School.

ST. LAWRENCE COUNTY MEDICAL SOCIETY.—The semi-annual meeting of the St. Lawrence County Medical Society will be held at De Kalb Junction, N. Y., on Tuesday, June 12, 1883, commencing at 12 M.

THE STATE MEDICAL SOCIETY OF VERMONT will hold its semi-annual meeting at Rutland, June 13 and 14, 1883.

PROFESSOR WILLIAM E. QUINE has been elected to, and has accepted the chair of Practice of Medicine in the College of Physicians and Surgeons of Chicago, Ill.

DEATH OF DR. BANKS.—Dr. James Lenox Banks died June 3d, at his residence in this city, at the age of fifty-one years. Dr. Banks matriculated in 1854 at the College of Physicians and Surgeons. He was graduated from that institution in 1857. He pursued the higher branches of his studies in foreign institutions for two years, and in 1859 began the active practice of his profession in this city. He was a member of the American Medical Association, the New York State Medical Society, the New York Pathological Society, the New York County Medical Society, the New York Academy of Medicine, and the Medico-Legal Society. He was also consulting physician of the Presbyterian Hospital and of the Presbyterian Home for Aged Women. He was a member of the Boards of Trustees of the College of Physicians and Surgeons and the Lenox Library, a member of the Board of Managers of the American Bible Society, and was a member of the American Geographical and New York Historical Societies.

THE AMERICAN NEUROLOGICAL ASSOCIATION meets in this city on June 20th, 21st, and 22d. There will be five sessions, the first beginning at 2.30 P.M. Papers are to be read by Drs. Robert T. Edes, of Boston; C. K. Mills, of Philadelphia; Burt G. Wilder, of Ithaca; McBride, Morton, Amidon, and others, of New York. Dr. E. C. Seguin has sent a communication entitled the "Insane of Spain and their Asylums." A dinner at Delmonico's to the President, Dr. Edes, and the members, will be given by Dr. Amidon on the evening of the 21st.

THE PRACTITIONERS' SOCIETY OF NEW YORK, at its annual meeting June 1st, elected Dr. Robert F. Weir, President, Dr. C. L. Dana, Secretary.

HOMŒOPATHY IN ENGLAND in the last decade has unmistakably lost ground. In 1853 there were 213 homœopaths; in 1862, there were 218; in 1871, 278; in 1880, 275.

American Medical Association.

Thirty-fourth Annual Meeting, held at Cleveland, O., June 5, 6, 7, 8, 1883.

(BY TELEGRAPH TO THE MEDICAL RECORD.)

TUESDAY, JUNE 5TH—FIRST DAY.

THE Association met at Case Hall, Cleveland, O., and was called to order at 10.30 A.M. by Dr. J. C. Scott, of Cleveland, chairman of the Committee of Arrangements.

Prayer was offered by the Right Rev. Richard Gilman, Bishop of Cleveland.

The President, **DR. JOHN L. ATLEE**, of Pennsylvania, then introduced General Edward S. Meyer, of Cleveland, who delivered the

ADDRESS OF WELCOME,

which was frequently interrupted by applause.

Ex-Presidents Gross, of Pennsylvania; Davis, of Illinois; Richardson, of Louisiana; Toner, of Washington, D. C.; and Baldwin, of Alabama, were then invited to seats upon the platform.

DR. SCOTT then announced that the Ohio State Medical Society had met and adjourned to be admitted as members of the Association during the present meeting. He also announced the general programme for receptions and other entertainments. In closing he directed attention to

THE BLANK WHICH DELEGATES AND PERMANENT MEMBERS WERE REQUESTED TO SIGN

before being permitted to register.

It was to the effect that every signer should make a binding acknowledgment

TO SUPPORT AND DEFEND THE CONSTITUTION, BY LAWS, AND CODE OF MEDICAL ETHICS OF THE ASSOCIATION.

The pledge was as follows: "I will use my best efforts to maintain the same, and in testimony whereof, I hereunto affix my name."

NO MAN WHO COULD NOT SIGN THIS APPLICATION WOULD BE PERMITTED TO REGISTER EITHER AS DELEGATE OR PERMANENT MEMBER.

Certain protests were simply announced and referred to the Judicial Committee.

THE PRESIDENT'S ADDRESS.

DR. ATLEE then delivered the annual address, in which he expressed regret that the State of New York was not represented by delegates, and hoped that their absence would be only temporary, and that at the next annual meeting every State in the Union would be represented by delegates. He then directed attention to his own specialty, namely, that of being a graduate of sixty-three years' standing, and gave a brief sketch, simple and interesting, of his own medical life. Special reference was made to the University of Pennsylvania, to Caspar Wistar, Physick, Tanner, Parrish, McClellan, Hays, and a galaxy of others who labored in our profession during those early years. Only slight reference was made to the treatment of disease in that period, but mention was made of the treatment of the insane when the patients were confined in small cells in the basement, seldom having access to fresh air, and often nothing for a bed except straw. With regard to the lancet Dr. Atlee thought the

almost total disuse of this agent had been the cause of the loss of many valuable lives. The President closed with mention of the advantages which had been obtained by the adoption of the Code of Ethics, and in conclusion thanked the Convention for the high honor it had conferred upon him, and said that "at the close of a long life, one devoted to the study and the practice of medicine, notwithstanding its uncertainty, fatigue, and anxiety, and its bitter disappointment, he was satisfied that in no other career can man more fully accomplish his whole duty to his God and to his fellow."

On motion of DR. KELLER, of Arkansas,

A VOTE OF THANKS

was extended to the President for his interesting and able address, and the same was referred to the Committee on Publication.

On motion by DR. HAYES, of Pennsylvania, the members of the Ohio State Medical Society were invited to seats as members of the Association during its present meeting.

DR. BILLINGS, of the United States Army, presented a communication from the British Medical Association, asking the American Medical Association

TO CO-OPERATE IN THE WORK OF METEOROLOGICAL OBSERVATIONS

in their relation to the chemical history of disease. It was referred to the Committee on Atmospheric Conditions, of which Dr. N. S. Davis, of Chicago, is chairman.

An appeal from Dr. Dwight W. Day was referred to the Judicial Council.

DR. DIDAMA, of Syracuse, N. Y., presented resolutions forwarded by Dr. Tyndale, of New York. They were

CONCERNING METEOROLOGICAL CONDITIONS

and the establishment of an increased number of signal stations for observation, and petitioning Congress for aid in the matter. The resolutions were laid on the table, to be called up at to-morrow's session.

The permanent Secretary, DR. ATKINSON, of Philadelphia, then read the register, and on motion by Dr. Toner, of Washington, the names of all such were confirmed, no protests being entertained.

The Association then adjourned to meet at 9.30 A.M. Wednesday, June 6th.

WEDNESDAY, JUNE 6TH—SECOND DAY.

The Association was called to order at 9.30 A.M. by the President, and prayer was offered by Rev. Chase S. Pomeroy, D.D.

The Secretary announced the following

COMMITTEE ON NOMINATIONS.

W. O. Baldwin, Ala.; D. A. Linthicum, Ark.; W. F. McNutt, Cal.; H. K. Steele, Col.; T. Morton Hill, Conn.; W. Marshall, Del.; A. B. Van Velsen, Dak.; D. C. Paterson, D. C.; E. Foster, Ga.; C. T. Parker, Ill.; H. D. Wood, Ind.; W. L. Robertson, Ia.; W. L. Schenck, Kan.; L. S. McMurtry, Ky.; J. W. Dupree, La.; A. J. Fuller, Me.; J. J. Chisholm, Md.; C. A. Savory, Mass.; F. R. Owen, Mich.; P. H. Miller, Minn.; G. H. Gregory, Mo.; V. H. Coffman, Neb.; D. A. Watson, N. J.; E. Grissom, N. C.; H. D. Didama, N. Y.; W. M. Beach, O.; S. D. Gross, Pa.; A. Ballou, R. I.; R. A. Kinloch, S. C.; D. J. Roberts, Tenn.; H. C. Ghent, Tex.; Alex. Harris, Va.; J. M. Lazzell, W. Va.; S. C. Johnson, Wis.; A. L. Gilson, U. S. N.; J. R. Smith, U. S. A.; Truman W. Miller, U. S. Marine Hospital Service; W. R. Typton, New Mex.

DR. FOSTER PRATT, of Michigan, called up the

AMENDMENT TO THE CONSTITUTION

which he offered at the last Annual Meeting, to the effect that the law requiring the nominations for officers be made from those members present at annual meeting, shall apply only to president, vice-presidents, chair-

men and secretaries of sections, the assistant secretary, the chairman of the Committee of Arrangements, and the Judicial Council.

The proposed amendment was adopted.

DR. S. D. GROSS, of Philadelphia, presented a paper received from Dr. Oliver Wendell Holmes, with reference to the

MUSEUM AND LIBRARY OF THE SURGEON-GENERAL'S OFFICE,

at Washington, D. C. The communication directed the attention of the Association to the propriety of the members of the American Medical Association explaining to their senators and members of Congress the necessity for funds to build a fire-proof building for the preservation of the library and the museum; stating that an annual appropriation of ten thousand dollars for the library, five thousand dollars for the museum, and an additional sum for the index catalogue, should be promptly provided, and that a fire-proof building should be built.

The communication was signed by Drs. S. D. Gross, A. Flint, and O. W. Holmes.

DR. H. A. JOHNSON offered a preamble and resolutions concerning this subject; first, that the American Medical Association endorse the movement of urging upon Congress the importance of at once providing a fire-proof building for the preservation of the library and army medical museum; second, that the annual appropriation for the library should be sufficient to enable it to obtain all medical publications, and that it regards \$10,000 as a reasonable sum for that purpose. The third clause referred to the importance of continuing the publication of the index catalogue, and the fourth provided for the appointment of a special committee of five, of which the President should be *ex officio* member, to present the whole matter in suitable form to Congress, and also to call the attention of State and local societies to the action taken by this Association.

DR. N. S. DAVIS, chairman, then read a report from the Board of Trustees

ON THE SUBJECT OF JOURNALIZING THE TRANSACTIONS.

The report contained, first, the resolutions adopted at the last annual meeting to the effect that the interests of the Association would be promoted by the publication of its transactions in a weekly medical journal under its own control, instead of the annual volume, as heretofore, provided it could be done without involving pecuniary embarrassment, etc.; second, a resolution that a Board of Trustees be appointed by request to proceed as early as possible to arrange a plan of the medical journal, to be called

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

and that they send circulars explaining such plan and asking pledges of support by actual subscription to the members of the medical profession throughout the whole country, etc.; third, that the said Board of Trustees be and are hereby instructed to retain under all circumstances, in whatever plans of contracts it proposes to adopt, control over the use of the advertising as well as over all other pages of the journal that is proposed to be established, and that said board report in full at the next meeting of this Association the plans upon which it has been able to agree, together with the reply of the profession to its circular asking subscriptions to the proposed journal.

In accordance with the foregoing resolutions, adopted by the Association at the annual meeting in June, 1882, nine members were appointed to constitute the Board of Trustees. Immediately after the adjournment of the Association, a meeting of the board was held, at which the majority of the members were present, and Dr. N. S. Davis was elected president, and Dr. J. H. Packard secretary. The plan then originated was that the journal should contain thirty-two double columns of reading matter, each number to contain a department of original

articles, a department containing an editorial summary of the progress in various departments of medical science and practice, an editorial department proper, essentially devoted to discussing such topics as would be likely to promote the interests and the efficiency of medical organizations, both national and State, also a department of correspondence, and lastly, a department for miscellaneous items and intelligence.

Having agreed as to the general plan of the journal it was determined that forty thousand circular letters should be issued, accompanied by the same number of blanks for answer, with reference to operating the project.

The result of sending these circulars was, that about three-fourths of the entire number were absorbed in supplying fourteen States, leaving only a limited number to supply the remaining portion of the country, and it was estimated that had all been supplied the favorable responses would have been increased by at least twenty-five per cent. To the circulars which were distributed 2,150 answers were returned, of these, 12 were direct expression of opposition to the proposed change, 30 were equivocal, leaving 2,100 unqualified pledges to sustain the proposed journal in addition to these, over five hundred subscriptions were obtained from those who are not members of the Association. It was also fair, to assume that a certain proportion neglected to respond, who would probably become subscribers to the journal, and it was therefore safe to conclude that the aggregate subscription to begin with, would be 2,500, making an income of \$12,500 yearly. The proposed journal, without advertising sheets, can issue 3,500 copies weekly at an expense of \$8,000 annually, which would leave \$4,500 for editorial work and current expenses. But such a journal under reasonably fair business management would receive from advertisements, not less than \$5,000 annually. All of the editorial work is to be paid from \$6,000, which would leave a balance of \$3,500 to be expended for scientific investigation in such a manner as might be deemed proper by the Association.

At the last meeting of the Board of Trustees, after a careful analysis of all the returns and the estimates with reference to the expense of printing and publication, all the members unanimously voted to recommend to the association that a journal be published, being satisfied that it could be done without pecuniary embarrassment to the Association, and also recommended the following propositions:

First.—That the editor-in-chief take direct supervision of the entire work, and for business purposes he might employ a clerk competent to assist in all business matters.

Second.—That for assistants in editorial work the editor should engage one or more, specially qualified, to select and write up progress made in all departments in medical science and art, and give to each assistant of the editorial chair a fair compensation for the work performed. He should also secure reliable correspondents from all parts of the country and from abroad. It was also recommended that all advertisements of proprietary, trade-mark, or patent medicines, should be excluded from the sheets. It was also recommended that no advertisement be accepted bearing names of endorsers having title appended, believing it to be contrary to the letter and to the spirit of the Code of Ethics.

The board also recommended that the printing be done by the firm known as Tucker, Newall & Co., of Chicago, and that the place of publication be Chicago, Ill.

In conclusion, the Board of Trustees submitted the following resolutions:

First.—That the report of the board, just read, be accepted, and the recommendation therein contained be adopted with reference to establishing the *Journal of the American Medical Association*.

Second.—That the Board of Trustees be instructed to proceed with the publication of the *Journal* at as early a day as practicable, to take the place of the annual volume

of "Transactions." The other resolutions referred to the detailed arrangement with the treasurer, and closed with the statement that all orders upon the treasury for the disbursement of money must be endorsed by the president of the Board of Trustees.

DR. BRODIE moved the adoption of the resolutions.

DR. WILE, of Connecticut, moved as an amendment that the secretary be instructed to have the report printed, and that discussion be postponed until to-morrow, at ten o'clock.

DR. ATKINSON, permanent secretary, said that he was pleased with the report of the Board of Trustees, and tendered his full services to the Association for the furtherance of the new plan of publishing the Transactions.

The amendment was lost; the original motion by Dr. Brodie was nearly unanimously carried.

DR. MCMURTRY, of Kentucky, secretary of the Board of Trustees, stated that he had been instructed by the board to report to the Association that it had now selected Dr. N. S. Davis, of Chicago, as editor-in-chief of the *Journal*.

DR. DAVIS then took the floor, and spoke at some length with reference to the prospects of the *Journal*, the anxiety which it had given him, and asked the forbearance of the Association with reference to any shortcomings which might appear, and also that the members should not expect too much, and should not be too strict in their comparison of the *Journal* with the *British Medical Journal*, which had so often been held up for a pattern, for it must remember that the *British Medical Journal* had been the work of years.

He further announced that he expected to be able to issue the first number of the *Journal* early in July next.

He also resigned his position as member of the Board of Trustees, to take charge of the department on the progress of medicine, with the understanding that he was to have full access to the Medical Library.

DR. PALMER, of Ann Arbor, spoke in complimentary terms of the project of publishing the Transactions in journal form, and also of the editor-in-chief.

DR. COHEN, of Philadelphia, moved that the Board of Trustees be instructed, in addition to the *Journal*, to print annually a thin octavo volume containing the minutes of the Association.

This motion gave rise to discussion, participated in by Drs. Hibbard, of Indiana, Quimby, of New Jersey, and Byrd, of Illinois, and, on motion of Dr. Richardson, of Louisiana, the whole subject was referred to the Board of Trustees.

DR. BUSCH, of Delaware, moved that the Association, in consideration of the long services already rendered, and also the kindness, self-denial, and willingness to assume the duties of editor-in-chief of the new journal, tender a vote of thanks to Dr. N. S. Davis. Unanimously carried.

DR. DAVIS said he had been directed by the Judicial Council to state that that body assumed all responsibility in putting the pledge to support the Code of Ethics upon the blanks to be signed by delegates or prominent members before registering.

DR. PALMER, of Ann Arbor, asked if it was meant that, by signing this blank, the signer was to sustain the present provisions of the Code, or was to sustain the Code, whatever it might be.

DR. DAVIS answered that the Code as it now stands was meant, and that if the Association made alterations, that then the changes would be considered as binding.

DR. SCOTT announced certain ethical communications, which were referred to the Judicial Council.

ADDRESS OF THE CHAIRMAN OF THE SECTION IN PRACTICAL MEDICINE, ETC., BY DR. J. H. HOLLISTER, OF ILLINOIS.

In the development of medical science men have been compelled to grapple with some of the most intricate and difficult problems which can challenge investigation. In studying those higher relations which lie in part beyond

the limits of finite conception, reason may properly defer to faith, and seeking the guiding hand of revelation walk with a wisdom other than its own. But in medicine it is not so. Forces, mental and material, interchangeable, interdependent, and inseparable, manifest themselves in ways so manifold and with so many essential facts undiscovered, that reason is compelled to thread her way with steps slow and uncertain, sometimes in truth, oftentimes in error, ever painfully conscious of her weakness and of the mysteries which confront her on every side. Thus only may we account for the seemingly meagre fruitage which represent the labors for more than two thousand years of some of the ablest minds the world has ever seen.

Those great problems of health and disease, of life and of death which affect the well-being of the race have been matters of patient investigation by many of the foremost men in every generation, and many of them have wrought out work which will endure as long as literature shall survive. But the essential causes of disease have been in the main so obscure and their expressions so varied and complex that the best of men have been compelled to conclusions largely inferential.

In the absence of positive knowledge no man can lay the restraining hand upon the fancies and credulities of man, and medicine has ever been the fruitful field above all others for their exuberant development. Speculations have been piled mountain high by one generation of workers to disappear before another as chaff before the driving wind. But despite the winnowings there still remained some golden grains of truth, and the treasure-house has been slowly but surely enriched by these garnerings of the ages.

The speaker then passed to some topics which pertain to medicine in general. First we can congratulate ourselves that the year has been so prolific of trustworthy, accurate, and able workers; probably no year in the world's history has witnessed an equal amount of legitimate original investigation. The united labor of such men is destined to achieve results which could never be accomplished otherwise, and there is born of such work a sympathy and an enthusiasm which is becoming world-wide.

Second, the medical journalism of the year claims favorable comparison with any that has gone before;

AN ABLE LITERATURE IS GOING TO THE PRESS,

a wiser supervision is manifest, new and able contributors are coming to the front, and all departments of medical investigation are having an abler expression of their work.

More than in any year before, the centres of intensest study have been within the range of microscopic vision. The microscope commands the advance to-day, and assertions based upon its revelations can only be tested, accepted, or rejected upon authority equally skilled in the use of this instrument. In microscopy two subjects, more than any others, command attention at this hour. One is the composition of the blood, the other is the agency of microcytes in the production of disease.

The speaker then directed attention to the difference of opinion concerning

THE STRUCTURE OF THE RED BLOOD-CORPUSCLE,

also the discovery of the third corpuscle, and concluded with the statement that as the case now stands England, and not Italy, Norris, not Bozzozero, maintains priority in the discovery of this element of the blood.

Turning to the subject of

MICROSCOPIC ORGANISMS

the most prominent man that confronts us is Dr. Robert Koch, and this prominence is based upon his discovery of what is known as the bacillus tuberculosis. One very important point arises in connection with this question

—in fact a pivotal one, upon which all others must turn, namely, the presence of specific organisms in many forms of disease. But the main question is, Are these causative or only concomitants.

Somewhat extended reference was then made to the labors of Koch and others, to the micro-organism of leprosy, of gonorrhœa, of the vaccine pustule, and other affections. The question that concerns us most is not as to whether we can destroy bacteria but whether they have not a greater vitality than the tissues of the human body, and whether in the germicidal warfare the human organism will not first succumb.

In materia medica numerous new remedies have been brought forward, but none seemed sufficiently prominent to command special attention in the year's reports.

The speaker then directed attention to the fact that recently in Italy a law had been passed which prohibited the

SALE OF PATENT MEDICINES

throughout the kingdom unless the precise composition of the medicine is stated, and asked how long shall enlightened America fall so far behind Italy in the enactment and enforcement of similar laws.

In conclusion, Dr. Hollister directed attention to the following questions and suggestions: Is the time not nearly at hand when the medical men of the United States shall be prepared to institute something like the following action? Let the medical profession in each State, in such a manner as seems best, satisfactorily designate one of their number to constitute with a like appointed member from each of the other States a nominating board. Let it be the duty of this board to nominate a list of men suitable for appointment by the President as members of the Medical Bureau, to be constituted with specific powers and duties in this bureau, composed, perhaps, of ten members. Let the army and the navy and the marine service have proper representation. Let the members of this bureau be subject to removal only for cause, receive a salary of not less than ten thousand dollars annually, to be paid by those who are applicants for the degree of Doctor of Medicine. Let the laws of the various States be so modified that

THE POWER OF CONFERRING THE MEDICAL DEGREE

shall rest solely with this body. Let students graduated by the National Medical Bureau receive an honorary distinctive title, say, that of National Fellow of Medicine. To such a movement the colleges could offer none other than a selfish objection. He thought he could see in such a plan, wisely and impartially executed, the possibilities of a medical culture of the profession such as the world has not yet seen.

ADDRESS OF THE CHAIRMAN OF THE SECTION IN OBSTETRICS AND DISEASES OF WOMEN, BY DR. J. K. BARTLETT OF WISCONSIN.

Dr. Bartlett first directed attention to some of the topics in gynecological surgery. Two years ago his predecessor, Dr. J. R. Chadwick, referring to Emmet's operation, stated "That it could hardly be said to have passed through the stage of novelty to that of criticism; that it was destined to be a fertile topic for several years to come; when it could be assigned to its proper sphere and cease to excite discussion."

Prolonged observation has shown that undue influence was attributed to the lesion, and experience has proven that the relief claimed to follow the operation is not uniformly attained. A more definite understanding of the conditions requiring its performance, and the limits to which it should be restricted, as well as a more just appreciation of its real merits, have been thus attained.

BATTEY'S OPERATION.

Another operation which has been tested for some years is that of Dr. Battey. Most of the indications

which have been claimed to warrant it are now generally admitted. Some doubts still exist with reference to its ultimate results when performed to check uterine hemorrhage produced by myomata. There is some diversity of opinion concerning its efficacy for the relief of epilepsy, or hystero-epilepsy, and mania seemingly dependent upon or associated with ovarian troubles.

Dr. Bartlett then presented at some length the views entertained concerning

TAIT'S OPERATION,

and made somewhat extended reference to the writings of Thomas and Elliot, of New York, and Savage, of Birmingham.

Concerning this operation, some important advances had recently been made in

THE TREATMENT OF EXTRA-UTERINE PREGNANCY,

which appeared to offer a safer and a surer path out of this difficulty than any previously discovered.

The method of treatment by electricity was then referred to as illustrated by cases reported by Lusk, Emmet, Thomas, Garrigues, Rockwell, and others.

WITH REFERENCE TO TRANSFUSION IN POST-PARTUM HEMORRHAGE,

confidence in its practical efficacy in cases where death appears imminent has very much lessened in France, Germany, and England, and thus Dr. Lusk, one of our latest authorities, says that although theoretically it is the most rational method of treatment, practically it is unsatisfactory.

A somewhat extended reference was then made to the literature of the subject as presented by Garrigues, Barnes, Schwartz, Woodman, Hickford, Coates, and others. The next topic of the address was the

OBSTETRIC FORCEPS.

Special attention was directed to one of the latest additions to the instrument presented by Dr. Alexander Duke, of Dublin. It consists of tractors which are applied with the blades before they are locked. These can be attached to a belt about the waist of the operator, and with toe-caps upon his shoes to prevent slipping. The inventor claims an immense gain of power for shortening labor. He considers that there is more chance for the child, and less risk to the soft parts of the mother by pulling the head forcibly through the pelvis, than if allowed to remain and mold itself to the outlet. Dr. Bartlett thought that we should probably hear of a small electro-motor of one-horse power, so arranged as to do the pulling, and save the operator as well as the mother any exertion.

In referring to the views of various authors the statement of Dr. Goodell was quoted, viz., "to tell you the truth, such grave lessons to the mother, and for that matter to the child also, are so constantly brought to my attention that I am disposed to accept Baudelocque's dictum that, take it all for all, the forceps have been more injurious than usual to society."

Dr. Bartlett also commented severely and justly upon the motive for using the forceps which had been frequently given, namely, to secure time for other engagements, and in view of his own experience and the observations of others, he could not avoid protesting against this fashion of the time, in the name and for the sake of the mothers, as well for the ultimate repute of a useful but now much-misused instrument.

The next topic referred to was

THE USE OF ERGOT IN LABOR.

The object in introducing this subject was to suggest a reason for the wide difference in opinion which exists with reference to its usefulness in obstetrics. The writer had administered this drug for many years in cases not

very frequently seen—where the second stage of labor was retarded by insufficient contraction and no pelvic obstacles existed. He regards it as a valuable resource in such cases, and has never witnessed, in his own practice, the tetanic contractions attributed to it since he learned how to employ it. For this purpose he uses an infusion of the freshly and coarsely powdered kernels, about thirty grains to three drachms of water, giving a tablespoonful every thirty minutes until some effect is apparent.

In some cases the effect is obvious after one dose, in others two or three doses are required. In cases of nervous exhaustion on the part of the patient a full dose of quinine is also given. It was also added that the writer had made no use of an anæsthetic in labor save in some exceptional case of feeble uterine contraction, but where ergot was administered and pains became efficient, the anæsthetic was also used. How much modification of the effects of the former were produced by the latter agent he could not positively determine, but was sure they acted well together as an anæsthetic. The contrariety of views with regard to

THE USEFULNESS OF AN ANÆSTHETIC FOR THE RELIEF OF PAIN IN LABOR

also appeared to the writer to be explainable only upon the supposition that it had been improperly and injudiciously used by those who opposed it. He believed a diversity of opinion might be, and probably was, the result of faulty administration. There are three stages of anæsthetic effects which may be produced: 1st, a lessening or annulling of sensibility to pain; 2d, by increased dose, the abolition of intelligence; 3d, the abolition of mobility.

The method and object of anæsthesia in surgery and labor differed widely. For the latter it was rarely necessary to produce much more than its first effect, and this is produced *pari passu* with the pain. A little experience will soon teach the physician how to arrest its effect at this stage, or at least before the second stage is fully attained, and to vary the amount as may be required by different degrees of pain. There is no proof which the writer has ever seen that, used in such a manner, anæsthesia produces or tends to produce post-partum hemorrhage.

In conclusion, if an anæsthetic ever produced post-partum hemorrhage, injury to the child, or other than beneficial results, experience tells us it must be due to the impurity of the anæsthetic employed, or to want of that experience, discretion, and use which is necessary not only here, but in the use of all therapeutic measures employed for the relief of human suffering.

With reference to the use of antiseptics in private obstetric practice, the writer thought that none of the prophylactic measures which had been recommended so strongly were necessary in cases of complicated labor, and that some of them were absolutely dangerous.

He then spoke of

DANGERS ATTENDING INTRA-UTERINE INJECTIONS.

The conclusions which the writer thought could be legitimately drawn were that danger of poisoning after ordinary labor in practice is not such as to demand the precautionary measures which Dr. Barnes has suggested; that in many cases in which the lochia are offensive no general disturbance follows, and that cleanliness as thorough as can be attained and care as to general conditions are only usually necessary; that even in cases where rises of pulse and temperature occur vaginal irritation is frequently sufficient; that in cases where relief has followed the use of carbolic injections, vaginal or intra-uterine, the advantageous results do not so much depend upon antiseptics as upon the cleansing effects by even a simple fluid used in such a manner and quantity as to secure entire removal of any decomposing matters retained in the uterine or vaginal canal.

In conclusion, Dr. Bartlett referred to the necessity for careful constitutional treatment in pelvic disease, stating that it had often been observed, but that it had not received the attention which its importance demands. Specialism, when exclusively practised, is apt to produce narrowness of view. No one who has not received thorough training in general medicine, and has not tested, confirmed, and enlarged their natural thought attained by many years of general practice, is fitted for a specialist. When medical gynecology is thus studied and practised, aided by larger general, local, therapeutic, and hygienic resources, which such research in time will develop, the clearer and surer will be the diagnosis which the future will bring, and the time will come when the present brilliant triumphs of the surgical gynecologist will grow pale before the achievements of his medical co-workers.

DR. TONER, of Washington, presented his

REPORT ON NECROLOGY,

which was referred to the Publication Committee.

The Association then adjourned, to meet on Thursday, June 7th, at 9.30 A.M.

THURSDAY, JUNE 7TH—THIRD DAY.

The Association was called to order at 9.30 A.M. by THE PRESIDENT.

Prayer was offered by the REV. N. S. RULISON, D.D.

DR. KELLER, of Arkansas, called up his proposed amendment to the By-laws, permitting the Committee on Nominations to fix

THE TIME AND PLACE OF HOLDING THE ANNUAL MEETINGS.

The amendment was adopted.

DR. BACHELDER, of Providence, R. I., introduced the following:

Resolved, That a committee be appointed by the President, to consist of one or more persons from each of the States, who shall be members of this Association, to urge upon each legislature

THE ENACTMENT OF MORE STRINGENT LAWS IN RELATION TO ALL TOXICAL AGENTS.

The resolution was adopted.

DR. PRATT, of Michigan, referred to the death of William Farr, of England, and introduced a resolution expressive of high appreciation of the labors of this gentleman in collating vital statistics, and stating that his works are recognized by the medical profession of the United States as an enduring monument to his ability and learning as a physician and a worker in that department. The resolution was adopted.

DR. S. D. GROSS offered the following preamble and resolution:

Whereas, Good nursing is of paramount importance, and whereas the subject is one which strongly addresses itself to the common sense of every intelligent member of society; therefore be it

Resolved, That this Association, fully recognizing the importance of the subject, respectfully recommends the establishment in every county or town of schools or societies for

THE EFFICIENT TRAINING OF NURSES,

male and female, by lectures and practical instruction to be given by competent medical men, members of county societies if possible, either gratuitously or at such reasonable rates as not to debar the poor from availing themselves of this benefit. The resolutions were adopted.

DR. WALTER HAY, of Illinois, offered resolutions providing for the organization of a special section to be devoted to the subject of psychological medicine. Laid over for one year.

DR. N. S. DAVIS, of Chicago, reported from the Standing Committee upon

ATMOSPHERIC CONDITIONS AND THEIR RELATION TO THE PREVALENCE OF DISEASE.

The report was an abstract of what had been prepared, and was in accordance with the general plan established under resolutions of the Association, providing for three parallel sources of coincident observations in twelve different localities, Boston, New York, Philadelphia, Baltimore, etc.

The report was accompanied by extensive tables illustrating the work done by Professor Long and others, and it was stated, that as a result of the works of Professor Long, the quantity of organic matter daily in the atmosphere during the entire year had been estimated for the first time in this country, or in any other. Special attention was directed to one fact, namely, that not a physician in New York City could be secured to co-operate in making clinical observations.

The abstract of the report closed with the following proposition: That the committee be authorized to furnish their report for publication as a part of the transactions of the Association, and to continue the investigations now in progress, with the privilege of drawing upon the treasury for so much of the unexpended balance of the former appropriation as might be necessary. Second, that the thanks of the Association are hereby tendered to the Superintendent of the Signal Service, General Hazen, for his uniform courtesy and favors extended, and that he be requested to continue the same as the committee may require. The report was unanimously adopted.

The resolutions offered by Dr. Didama in behalf of Dr. Tyndale, of New York, at the session on Tuesday, were then taken from the table and referred to the Committee on Atmospheric Conditions.

DR. DAVIS then requested that Dr. Didama, of New York, be added to the Committee on Atmospheric and Ozonic Conditions. His request was granted.

DR. HEAD, of Indiana, introduced a resolution of sympathy with the wife and family of

DR. J. C. HUBBARD, OF ASHTABULA, WHO DIED SUDDENLY ON TUESDAY, WHILE IN ATTENDANCE AT THE ASSOCIATION.

THE PRESIDENT appointed the following

DELEGATES ABROAD:

G. J. Engelman, St. Louis; Wm. M. Finley, Altoona, Pa.; Walter L. Ziegler, Pennsylvania; M. H. Alter, Pennsylvania; R. B. Cole, San Francisco; J. H. Warren, Boston; C. H. Vonkleim, Hamilton, O.; Wm. M. Lawlor, San Francisco; Henry Martin, Boston; J. C. Hutchison, Brooklyn; A. M. Howes, Detroit; E. Borck, St. Louis; T. F. Prewitt, St. Louis; E. P. Allen, Pennsylvania; H. McCall, Michigan; I. N. Quimby, New Jersey; S. La Gordon, Maine.

DR. POLLAK, of St. Louis, introduced resolutions purporting to come from the St. Louis Medical Society, asking that the American Medical Association appoint a committee to take into consideration the

ADVISABILITY OF REVISING THE CODE OF ETHICS,

and to report at the annual meeting in 1884. The communication and the resolutions were laid upon the table.

DR. BRODIE moved that all papers before being read should secure the approval of the chairman of the section to which it was referred. The motion was laid upon the table.

On motion by DR. DAVIS, Dr. M. L. Nardyz, was received as a member by invitation.

ADDRESS OF THE CHAIRMAN OF THE SECTION IN SURGERY AND ANATOMY, BY DR. W. F. PECK, OF IOWA.

In reporting upon the progress made in surgical science

during the last year, it is recognized that many theories are announced as facts, which, when experience and demonstration shall have thoroughly tested them, may be eliminated, perhaps to reappear when the circle of professional experience again completes its revolution. The greatest progress has been made in operative surgery, although other departments have been constantly endeavoring to add new light and additional results to our already extensive accumulations. It is not claimed that large numbers of new operations have been originated and performed, but it is evident that a better understanding of pathological conditions has stimulated surgeons to establish a standard for operations hitherto ventured upon in rare and extreme instances. In pathology, the microscopist has been active in trying to define and locate the germ cause of disease. Certain it is that during the year there has been developed a strong feeling in favor of Koch's views concerning bacilli and their alleged tubercular relations, that these peculiar microgerms exist there can be no longer any doubt, but whether they are the cause of the tubercle or whether the tubercle develops them the profession has not yet made sufficient progress to justify an unequivocal statement.

Dr. Peck then referred to the views entertained by Dr. Koch, and Spina, his opponent. The surgeon is interested in these investigations because it is thought by many excellent men that germs play a very important part in causing infection, inflammation, pyæmia, septicæmia, abscess, gangrene, etc., and if this view is sustained it will be conceded that it will tend to give new and more efficient reasons for

THE USE OF ANTISEPTICS IN PRACTICE.

The condition and the problem of the management of wounds and other pathological processes, by means of the so-called antiseptic methods, suggests the production of greater confidence in the details of operative procedure, and scrutinizing attention to extreme cleanliness in the minutiae of practice. The speaker then referred to the use of carbolic acid and other antiseptics, and to the experience of Thornton, Spencer Wells, Lawson Tait, Billroth, Esmarch, and others, and said that it could not be successfully argued that a lessened mortality was alone due to the use of antisepticism as practised by Lister. It would be immediately asked, "How else can these alleged great changes in practice be explained?" If everything that is used to keep a wound clean, and to insure thorough drainage is called antiseptic practice, then no adequate explanation can be offered. Is not the experience of Mr. Keith as wonderful as the tabulations of the Vienna or Kiel surgeons? Yet it is admitted that most of the leading surgeons of England are thoroughly wedded to the antiseptic treatment of wounds, still there are to be found a few excellent teachers and operators who most reverently believe that nature, with assistance from the surgeon, will do more to save limb and life than the surgeon can do who depends upon restricted antisepticism.

Dr. Peck had opened the abdomen, in all, forty-eight times; in forty-six instances for the removal of ovarian growths; once for an adherent ovary, and once for intestinal obstruction.

In the first thirteen cases there were six deaths. The operations were made under the spray, and the wounds were treated with carbolic-acid solution. In the remaining thirty-one ovarian operations, also in oöphorectomy and in cases of laparotomy, the spray was not employed. The two last-mentioned cases recovered, and out of the ovariectomies there were four deaths. He was of the opinion that many of the wonderful results accomplished by numerous surgeons throughout the country were secured not so much by means of the spray and carbolic acid, as by the extraordinary care and attention which they gave their cases.

Among the new and important instruments which have been presented, mention was made of the

UNIVERSAL OR COMPOUND RATCHET JOINT,

which has been offered by Dr. Stillman, of New York, which can be adjusted at pleasure and permits of universal motion. Perhaps one of the most important steps that have been taken is the utilization of the electric light, both as a means of diagnosis and as an aid in making operations in cavities, and in places where the natural light can be used only with uncertain effect. For this purpose Swain's lamp has been frequently used, which in size is not larger than an ordinary bean, and with it the interior of the bladder, the pharynx, the larynx, the cesophagus, stomach, and ear have been illuminated.

Decided progress has been made in

LOCATING METALLIC SUBSTANCES IN THE TISSUES OF THE BODY

by means of the induction balance by Prof. Graham Bell. Sir Henry Thompson has offered some very valuable information concerning

THE DIRECT EXPLORATION OF THE BLADDER.

He makes a limited incision in the membranous portion of the urethra and then passes the index-finger along the back and through the neck of the bladder, where, by the aid of supra-pubic pressure, a free and satisfactory exploration of the cavity and walls is permitted. The year has greatly added to our previously meagre knowledge of surgical procedure in intra-abdominal pathology. Statistics show that less hazard is encountered in attempting to extirpate tumors, malignant growths, and removing the causes of intestinal obstruction than was formerly supposed.

THE FEASIBILITY OF GASTROTOMY

has been established by experience collected during the past year. Up to January, 1883, there had been performed thirty-six operations for the removal of some portion of the stomach or duodenum for cancer, gastric ulcer, inflammation and destruction of the colon. Unless the greatest discretion is shown, however, in the selection of cases for operation, the mortality cannot be otherwise than very high. In connection with this operation there were two very important questions to be answered. First, If the cancer, for which nearly all the operations are performed, is due to a general cause, can the surgeon expect the patient to receive more than temporary relief from the operation? Second, Will the aggregate life in those cases in which the operation is successful, be greater than it would be in those cases in which death occurs as the direct result of the disease?

LAPAROTOMY

is an operation which is progressing with much favor in America and France. Opening the abdomen to relieve intestinal obstruction is not only inviting, but operators who have had experience in making ventral section proceed with less hesitation to search within the abdomen for arrested alimentary action than they have heretofore done. Dr. Peck then gave the history of some cases which illustrated the liability to the formation of adhesions between the cæcum and the surrounding parts, and also illustrated the relief which might possibly be obtained by operative interference. Prof. Loretta, of Bologna, had performed the operation of

STRETCHING THE CONSTRICTED PORTION FOR STENOSIS OF THE PYLORIC ORIFICE

of the stomach. The number of operations thus far performed were four, with two recoveries. It will at once be conceded that a careful study of the history in any given case must result in unequivocal diagnosis.

Dr. Peck then directed attention to one of the causes of death in this department of operative surgery, illustrated by a case. Post-mortem examination was made nine hours after death. No foreign material of any kind was found inside of the abdominal cavity. All of the organs were apparently healthy, except that in the right

ventricle of the heart there was a large, white fibrinous ante-mortem clot. What caused the blood-clot? It is not enough to say that in any given case death came as a result of fibrin collection on or around one or more of the heart-valves. There must be a further cause which influences the vital fluid.

Dr. David Newman, of Glasgow, has performed

THE OPERATION OF NEPHRORRAPHY

upon a woman, it being the first operation made in England for floating kidney. The capsule of the kidney was stitched to the margin of the incision, and deep button-hole sutures were passed through the kidney, thus fixing the organ in its natural position. The patient recovered, and is now well. Dr. Wm. Thomson, of Dublin, has added another case of

LIGATURE OF THE INNOMINATE ARTERY,

the patient living forty-two days. Dr. Arthur E. Baker, of London, has practised a novel and apparently

SUCCESSFUL OPERATION FOR VARICOCELE.

After washing the scrotum thoroughly, he separates the veins of the cord from the vas deferens, then passes a needle threaded with twisted silk behind the veins, after which the veins are permitted to drop back, when the needle is returned in front of the veins, which are thus secured in the loop of the ligature through the original opening. The thread is then made tense, and the veins are brought close to the walls of the scrotum, and the ligature is well tied, cut close to the knot, and then allowed to return with the veins to the scrotal cavity. The results reported are such as to commend a further trial of the operation. Reference was made to two interesting and remarkable operations performed upon the sternum and its contiguous relations by Dr. Keuster, of Berlin, and Prof. Koenig, of Göttingen. They were performed for malignant growths, illustrated bold and scientific manipulation, and at the same time indicated how nearly, dexterously handled, a knife and finger may reach the vital organs of circulation and respiration without compromising life. Whether or not the operations were necessary, Dr. Peck did not propose to discuss. Important additions had been made to our surgical literature, and special reference was made to two volumes, one on surgery and one on anatomy. That in surgery by D. L. Huntingdon, who succeeds the late lamented surgeon Geo. A. Otis, has been performed, and the world is now in possession of the most complete record of wounds and injuries resulting from war that has ever been produced. Dr. Harrison Allen, of Philadelphia, has produced a part of what promises to be an excellent treatise on human anatomy, including medical and surgical relations.

A real and most substantial advance is being made in surgery in connection with railway corporations. Many of the leading lines have introduced into their system of management surgical departments, the objects of which are: first, to enable the company to more economically manage its affairs, and secondly, to insure to those who are unfortunate enough to receive injuries the certainty of receiving the most complete surgical skill. The ultimate benefit which is certain to accrue to the profession is the accumulation of a vast amount of statistical information which will be of great service in neural pathology, because it is a well-known fact that in many cases the results of alleged railway accidents are not sustained by the systematic expressions of injured tissues and organs. The instances are exceedingly rare where pathology which is the result of injury does not fail to receive corresponding endorsement by the surgeon.

On the other hand, the surgeon often finds himself unable to satisfactorily interpret the inharmonious description of symptoms furnished by the person who sees a moneyed equivalent at the end of a well-established concussion of the brain or spinal cord.

The surgical bureaus of these corporations will, by their collected experience and tabulations, be qualified so as to be able to furnish much valuable information to both the judicial and popular tribunals. Then justice to pathology and rewards to individuals will receive fairer and more honorable administration.

ADDRESS OF THE CHAIRMAN OF THE SECTION IN STATE MEDICINE,

by FOSTER PRATT, M.D., of Michigan.

After making a few introductory remarks, the speaker said that no noteworthy advance had, during the past year, been made in either department belonging to this Section. The Section was established in 1873, and has now completed its first decennial period.

Not quite fifteen years have passed since systematic work in sanitary science began in the United States. As we compare the sanitary work of the year 1883 with its beginnings in 1873, there is room for congratulation throughout the country that during these ten years so much has been accomplished. What has been accomplished? Sanitary organizations and machinery have been developed and to a good degree perfected; men have been educated to some degree for their special work; books, magazines, and special articles have been indefinitely multiplied, and in all these directions it is clearly indicated that the popular interest and approval of sanitary knowledge and work is well established, and that the people are desirous of continued work and observation.

The work of sanitary reform has manifested itself in the system of

LIGHTING AND VENTILATING OUR HOMES,

our school-houses, and other public buildings; and the earth, and the air, and the water are being investigated with wholesome suspicion, to clear out their unwholesome condition. Municipalities without number are now supplying themselves with water from purer sources than formerly, and their accumulated filth is being destroyed or removed or disinfected, and their new filth is being carried away by properly constructed sewers.

The superstitions of earlier days have been steadily giving way under improved sanitary condition, and in towns both large and small there is unmistakable evidence of

THE GROWTH OF SANITARY KNOWLEDGE,

and the people are emancipating themselves from the thralldom of old views which were but the harbingers of epidemics and contagious diseases. They have come to learn that by proper observation of sanitary law they may escape, to a very great extent at least, the results which follow these epidemics and contagious affections.

TO AVOID OR PREVENT DISEASE

has come to be recognized as the principal method of counteracting the influence of these agencies. Prior to 1873 but two States in the Union had established State boards of health, Massachusetts and California. Since that date others have been added, so that at the present time thirty-eight States practically proclaim that the safety of the people is the supreme law; that public health is public wealth, and that to promote the health of the people is the first duty of the statesman.

There are yet other States which have either neglected or refused to enter upon this warfare against disease. It might be true that superstition, or even the running fire of derision from physicians, or evolution, or all combined, might delay the end desired in sanitary reform, but its consummation could not be postponed for any considerable length of time. Doubtless many years would pass before every State in our Union would be engaged in battling against the ills of humanity. When we have a health board in every State, and National board of health with proper powers and money, then we

may ask what will the Congress of the United States do when we ask for bread—will they give us a stone? Missouri is the latest recruit to the number of States in which health boards have been established, and Ohio and Pennsylvania have made strenuous efforts to join the majority.

The aid and agency of the American Public Health Association in producing this result must be recognized, but above all, and the most important of all agencies to mould public opinion, is the individual doctor who has his own personal sphere of action and influence.

He has led the way, and may still continue to demonstrate the success of the movement, because facts and reasons have been his principal weapons of warfare. Facts have demonstrated that small-pox can be prevented, also that isolation with reference to other communicable diseases has been a means of counteracting contagious influences, and facts and reasons on a grand scale are equally useful. Dr. Pratt then referred to the work which the late William Farr, in England, began in 1837, and in which he continued to labor, in compiling vital statistics, and during thirty years accumulated pile upon pile, and added demonstration to demonstration, which finally led to the passage of the British medical act, the crowning labor of his life. It was to Farr's tables and deductions and demonstrations that could be traced the basis upon which all of our sanitary structures in the United States were founded.

After reviewing the influence which statistics on such a large scale can exert, the speaker said, should be assured that the average mind is responsive to the laconic deductive philosophy. But we shall be asked, What is it that may be done by State boards of health which justify their organization and power? To answer this question Dr. Pratt referred to the sanitary work which had been performed in his own State of Michigan, and detailed at some length the work as it appears in the volumes of annual reports, where appear papers which were written upon special subjects by men especially qualified to write upon these subjects—by doctors, clergymen, chemists, and editors, who had seen how to utilize the press for sanitary purposes.

The volume contained vital statistics from one thousand four hundred local boards in the State, and all of this work and much more had been performed at an expense of less than six thousand dollars.

Does it pay? He was sure of the answer that would be given by his audience. But what would be the response from the people? Dr. Pratt then dwelt at some length upon the influences which should be brought to bear upon the people to convince them of the utility of this work in sanitary reform, such as would convince men and women of its practical value. He said "himself" or "herself" because it was a fact that in Massachusetts, which was the first State to organize a State board of health, the initial step in sanitary reform was taken by a lady.

Continuing, the speaker presented the effect which sanitary reforms produced on the duration of life. And it appeared from English statistics that there had been an increase during the last seven years in the length of human life, among males of two years and among females of three years and a half; in other words, that male life had been increased five per cent. in duration, female life more than eight per cent., and the average increase in the duration of human life was six and one-half per cent. throughout England.

He asked the significant question, Is not this proof that sanitary organization is of sufficient advantage to be accepted and adopted by the masses? and he hoped that the time would soon come when it would be so generally recognized that in newly organized States the people would be able to prevent the evils which have existed in the older States.

Are we doctors responsible for any of the tardy movements in this direction?

He was not about to preach a sermon or read a lecture, but have we not crippled sanitary work by claiming for it results that are not yet warranted? Have we not urged as facts in sanitary science what in truth is nothing more than a theory, sometimes a mere theory too?

Our advanced ideas regarding germs, etc., what are these but stumbling-blocks in the way of laymen and intelligent legislation? When we can prove to laymen that a certain stream is polluted near its source, causes sickness and death to many families, they will believe your established facts. But how much will they know about your theory concerning the precise nature and function of the morbid agency that is being carried by the stream, especially if it lead you to a somewhat too scientific method of meeting the question which is of practical moment, how to purify the stream.

In this country all sects in medicine, like all systems and sects in religion are equal before the law.

Have some of us been somewhat too arrogant or exclusive in the organization or proposed organization and management of this public affair? In private relations, in private practice we hold to the rules of the code that ignores as unscientific all medical systems based upon exclusive dogmas, but in public when we meet all sorts of doctors, and their patrons as well as our own, as taxpayers and citizens to discuss and devise measures of common interest, is not one man's medical theory as good as another's? Dr. Pratt called especial attention to the remarkable unanimity with which the State Medical Societies, the American Public Health Association, and the American Medical Association, expressed their approval of the organization of a National Board of Health. He then made brief reference to the bacillus and other micro-organisms, and stated that before sanitation can avail itself of these discoveries much must be learned in regard to the life and propagation of disease-germs; atmospheric, external, and other conditions must be thoroughly studied. As medico-legal sanitarians, waiting for firmly established truth, we must, metaphorically speaking, hold our breath.

THE TREASURER'S REPORT

showed a balance in the treasury of \$903.93. The librarian reported that the number of distinct titles in the library is 1,817, in 5,713 volumes, inclusive of pamphlets. He recommended that the home and foreign journals be continued, and that two hundred dollars be placed at the disposal of the librarian for purposes of securing and binding pamphlets and journals, also that the subscription of fifty dollars be continued for the Index Medicus. The report was accepted and the recommendations adopted. The Committee on Publication, Dr. Fricke, chairman, made its report, which was received and ordered entered upon the minutes.

DR. EUGENE GRISSOM, of Raleigh, N. C., then read the

REPORT OF THE COMMITTEE ON NOMINATIONS.

President—Austin Flint, New York. *Vice-Presidents*—R. A. Kinloch, South Carolina; T. B. Lester, Kansas City; A. L. Gihon, U. S. Navy; S. C. Gordon, Maine. *Treasurer*—R. J. Dunglison, Pennsylvania. *Librarian*—C. H. Kleinschmidt, District of Columbia. *Chairman Committee of Arrangements*—A. Y. T. Garnett, Washington, D. C. *Assistant Secretary*—D. W. Prentiss, Washington, D. C. *Members Judicial Council*—F. D. Cunningham, Virginia; H. O. Marcy, Massachusetts; W. O. Baldwin, Alabama; J. S. Billings, U. S. Army; N. W. Miller, U. S. Marine Hospital Service; E. Grissom, North Carolina; R. N. Todd, Indiana, to fill vacancy; E. W. Clark, Iowa.

Committee on Necrology—J. M. Toner, Washington, D. C., Chairman; R. F. Michel, Alabama; Wm. Turner, Arkansas; H. M. Gibbons, Jr., California; C. Dennison, Colorado; C. H. Pinney, Connecticut; J. B. Van Velsor, Dakota; H. F. Campbell, Georgia; J. H.

Chew, Illinois; W. Lomax, Indiana; S. B. Chase, Iowa; C. V. Moltram, Kansas; W. B. Reynolds, Kentucky; E. Lewis, Louisiana; A. J. Fuller, Maine; C. Johnson, Maryland; J. H. Gilman, Massachusetts; W. F. Breakey, Michigan; F. A. Dinsmore, Minnesota; W. Johnson, Mississippi; W. H. Mudd, Missouri; R. C. Moore, Nebraska; H. D. Didama, New York; G. F. Welch, New Jersey; H. Haywood, North Carolina; S. Loving, Ohio; F. Woodbury, Pennsylvania; W. E. Anthony, Rhode Island; J. B. Lindsley, Tennessee; M. D. Knox, Texas; O. F. Fassett, Vermont; L. B. Edwards, Virginia; S. L. Jepson, West Virginia; E. L. Boothby, Wisconsin; W. S. Forwood, U. S. Army; A. L. Gihon, U. S. Navy; W. Wyman, U. S. Marine Hospital Service; F. P. Porcher, South Carolina; W. H. Page, New Mexico; Wm. Lee, District of Columbia; W. Marshall, Delaware; W. H. Carpenter, Oregon.

OFFICERS OF SECTIONS.

Practice of Medicine—J. V. Shoemaker, Pennsylvania, Chairman; W. C. Wilecomm, Secretary. *Surgery and Anatomy*—C. T. Parks, Illinois, Chairman; H. O. Walker, Michigan, Secretary. *Obstetrics and Diseases of Women*—T. A. Reany, Chairman, Cincinnati, O.; J. T. Jelks, Arkansas, Secretary. *State Medicine*—D. J. Roberts, Tennessee, Chairman; Franzoni, Washington, Secretary; J. Cochran, Alabama; J. J. McAlmat, Arkansas; W. D. McNutt, California; Chas. Dennison, Colorado; C. W. Chamberlain, Connecticut; J. B. Vanvelser, Dakota; J. P. Logan, Georgia; O. C. Dewolf, Illinois; G. Sutton, Indiana; W. S. Robertson, Iowa; D. W. Stormont; Kansas; J. P. Thompson, Kentucky; S. C. Chaille, Louisiana; S. H. Weeks, Maine; John Norris, Maryland; H. J. Bowditch, Massachusetts; F. K. Owen, Michigan; C. N. Hewitt, Michigan; N. M. Milligan, New Mexico; S. Townsend, D. C.; M. Simmons, South Carolina; S. P. Bush, Delaware; H. Carpenter, Oregon; H. A. Gault, Mississippi; L. Hall, Missouri; L. Larsh, Nebraska; E. M. Moore, New York; E. M. Hunt, New Jersey; J. McKee, North Carolina; T. L. Neal, Ohio; R. J. Dungleison, Pennsylvania; C. H. Fisher, Rhode Island; C. C. Fite, Tennessee; T. D. Wooten, Texas; S. W. Thayer, Vermont; J. L. Cabell, Virginia; Moffit, West Virginia; J. T. Reeve, Wisconsin; J. R. Smith, United States Army; J. M. Brown, United States Navy; T. H. Bailhoche, United States Marine Hospital Service. *Ophthalmology, Otolaryngology, and Laryngology*—J. J. Chisholm, Baltimore, Chairman; Thompson, Indianapolis, Secretary. *Diseases of Children*—Wm. Lee, Maryland, Chairman; W. R. Tipton, New Mexico, Secretary. *Oral and Dental Surgery*—T. W. Brophay, Illinois, Chairman; J. S. Marshall, Illinois, Secretary.

Place of Meeting, 1884—Washington, D. C., first Tuesday in May.

The report was also accompanied by the statement and a letter from Dr. A. L. Gihon, that the rumor that he was unfavorable to the Code of Ethics was without foundation, and that he was unqualifiedly an adherent of the present Code and should be governed by its requirements.

On motion by Dr. W. S. DAVIS, the report was received and adopted.

DR. DIDAMA, of Syracuse, then read the following letter from Dr. Austin Flint, addressed to him as a member of the Committee on Nominations:

"Circumstances render it necessary for me to return early to-day, June 7th, to New York. Will you kindly express to our brethren, the Members of the American Medical Association, with my sincere thanks, an assurance that I thoroughly appreciate the great honor which has been conferred on me. I accept the honor, feeling assured that I may confidently expect co-operation and indulgence in my efforts to fulfil the duties which it involves."

The Association then adjourned, to meet at 9 A.M. Friday.

FRIDAY, JUNE 8TH—FOURTH DAY.

Association called to order at 9.30 A.M. by the President. Prayer by REV. C. T. COLLINS.

Amendment providing for representation from Medical Bureau United States Indian Service was laid upon the table.

DR. TONER withdrew his proposed amendment that the office of Permanent Secretary be vacated.

The proposed amendment to allow the Chairmen and Secretaries of Sections to add earnest workers, and that the Librarian be made a permanent officer, was laid upon the table.

The proposed amendment to allow permanent members to vote gave rise to discussion, and finally the whole subject was indefinitely postponed.

DR. DAVIS, from the Judicial Council, reported that the petition of D. W. Day be returned, with leave to supplement the paper with a written statement of the character of the new evidence he proposed to introduce. Further, that in the case of D. H. Goodwillie, of New York, the Council decided, that his registration be cancelled, and the annual dues be returned.

DR. TURNBULL offered a resolution that the Legislature of each State be petitioned to pass

LAWS REQUIRING RAILROAD EMPLOYEES TO BE EXAMINED

regarding their hearing before taking charge of any railroad train. Referred to Section on Otolaryngology.

DR. PRATT offered a resolution, that being impressed with the importance of the Parliamentary Bills Committee of the British Medical Association, the American Medical Association urge upon Congress the subject of

COMPETENT MEDICAL SANITARY SERVICE ON BOARD ALL TRANSATLANTIC OCEAN VESSELS;

that a committee of five be appointed to report on the subject at the next Session. Adopted.

DR. BELL, of New York, offered a resolution that all papers hereafter offered, except the address of the President and the Chairmen of Sections, shall be first referred to the Trustees of the *Journal* for classification and appropriate reference. This gave rise to discussion, and finally was tabled.

THE PRESIDENT announced as the committee to further Dr. Pratt's resolution, Drs. Bell, Gibson, Marcy, Quimby, and H. H. Smith.

DR. BRODIE moved resolutions of respect to the memory and labor of the late General J. K. Barnes. Adopted.

DR. KELLER offered a resolution that in the near future, cremation will become a necessity in large cities, and populous districts in the country, and asked that it be referred to the Section on Hygiene. Carried.

THE PRESIDENT appointed the following delegates to the Canadian Medical Association: Drs. W. Brodie and H. L. Walker.

DR. TONER moved the thanks of the Association to the Secretary and Treasurer for the efficient and satisfactory manner in which they have discharged their duties. Adopted.

DR. BLOUNT, Chairman of the Section on Diseases of Children, was granted the privilege of submitting his address without reading.

DR. QUIMBY offered the usual resolution of thanks to the Committee of Arrangements and citizens of Cleveland for their entertainments, which was unanimously adopted.

THE PRESIDENT invited the Vice-Presidents elect to the platform, made a few remarks complimentary to the President elect, bade the Association an affectionate farewell, after which DR. LESTER, of Kansas City, Second Vice-President, took the Chair, and declared the Association adjourned, to meet on the first Tuesday in May, 1884, at Washington, D. C.

AMERICAN SURGICAL ASSOCIATION.

Fourth Annual Session, held at Cincinnati, Ohio, May 31, June 1 and 2, 1883.

(Special Report for THE MEDICAL RECORD.)

THE fourth annual meeting of the American Surgical Society was convened at 10 A.M., July 31st, at College Hall, Cincinnati.

PROF. S. D. GROSS, M.D., of Jefferson College, Philadelphia, presided, and DR. J. R. WEIST, of Richmond, Ind., performed the duties of Secretary.

THE PRESIDENT read a brief

ANNUAL ADDRESS,

congratulating the Association upon its rapid growth and present prosperity, upon the fact that there had been no losses by death during the year, and recommending the adoption of an amendment to the by-laws increasing the limit of membership from one hundred to one hundred and fifty, and also enlarging the Council from four members to seven.

DR. P. S. CONNER, Chairman of the Committee on Reception, delivered a brief

ADDRESS OF WELCOME,

and invited the Fellows to attend the annual banquet at the Gibson House at 8.30 P.M., June 1st, at the close of the second day's session.

THE PRESIDENT asked that the Council act at once upon nominations for fellowship, in order that the new members might take part in the meetings.

It was announced that only eleven vacancies existed.

In the absence of Dr. Cole, one of the members of the Council, Dr. Moore, of Rochester, was appointed temporarily to act in his place.

A letter was read from the venerable Prof. Willard Parker, acknowledging the honor conferred upon him by the Association in electing him to fellowship, which he accepted with pleasure. From the

TREASURER'S REPORT

it was shown that the Association has at present on hand a balance of \$2,270.31. Drs. Mears and Benham were appointed auditors of this report.

HAVE WE ANY THERAPEUTIC MEANS, AS PROVEN BY EXPERIMENT, WHICH DIRECTLY AFFECT THE LOCAL PROCESSES OF INFLAMMATION?

C. B. NANCREDE, M.D., of Philadelphia, Pa., read a paper on the above, of which the following is an extract: Careful study of the essential processes of various morbid conditions, has often led to the theoretical employment of therapeutic measures, which by their apparent practical use have confidently encouraged their future employment.

If we find by experiment that our *à priori* therapeutics, when experimentally applied in the case of animals, actually produce the precise effects which we have predetermined will probably prove efficacious, then we can hardly go astray in confidently applying similar treatment to the human subject. If we find clinical discrepancies, it must be our aim to ascertain the exact limitation of the remedy for good or evil, and the precise indications for its employment, instead of thrusting it contemptuously aside when we fail of the expected result, the failure being probably our faulty method of applying the treatment, and not self-inherent. Upon the other hand, we must always hold before our eyes the experimental mirror of what has been and can be effected, and not expect to do what we have demonstrated is an impossibility.

The paper was avowedly written in advocacy of blood-letting in general, but chiefly of the local abstraction of blood. It referred only to the early stages of inflammation. No direct effect can be exerted upon the tissue-

changes of that process when the inflamed part has returned to its foetal state, was merely embryonal tissue, only a step farther from which was pus.

The writer enumerated the vascular changes, as described by Burdon-Sanderson, but said that, contrary to expectation, the circulation at the outset is accelerated in the dilated vessels, but the rate soon became normal and was succeeded by a slowing, then an oscillatory movement, temporary stagnation, again a resumption of the flow, and finally permanent stasis with the crowding of the vessels, especially in the veins, with cell elements, so that the previous clear space existing along the walls of the arteries can no longer be detected. The obstructions seemed to consist solely of red cells, which were so closely packed as to render "their individual forms . . . scarcely distinguishable." Free diapedesis of the white blood-cells now took place, with exudation of liquor sanguinis, both processes having commenced when incipient stagnation set in. In this connection he related the experimental conclusions of Ryneck and H. Weber.

On account of the stimulating effects of the exudation the cells of the part returned to the foetal state and pus resulted. The whole process of inflammation was summarized in the words of Burdon-Sanderson. The white blood cells in the early stages of inflammation are sluggish and then cease to move in the absence of oxygen, and were active in proportion to the amount of that substance present. It was also indisputable that the red cells were the main carriers of oxygen, and that if their numbers were relatively increased to the fluid in a given bulk of blood, especially if, as in inflammation, both the necessity and capability of the cells of the tissue making use of the oxygen were removed, at once an excess of oxygen, *i.e.*, an increased amœboid action of the white cells, not only was possible but *became a necessity*.

The theoretically perfect remedy for incipient inflammation must comprehend the following effects: it must either lessen the vis-a-tergo of the heart's action so as to prevent injury to the vascular wall by over-distention and the consequent outpouring of liquor sanguinis; it must prevent such an ingress of blood into the affected area as would produce the excess of oxygen, the migration of cells, the blocking up of the lymph-spaces, etc., or, what would practically amount to the same thing, lessen the difficulty of escape on the venous side.

The Doctor then made his conclusions as referable to treatment of traumatic inflammations.

The discussion was opened by DR. CAMPBELL, of Augusta, Ga., who strongly favored blood-letting. He taught his students the value of blood-letting, which he placed next to morphia in the list of therapeutic agents. He advocated its value in puerperal convulsions, and thought that instead of there being a state of anæmia of the brain, the woman in child-bed was full of blood, that by blood-letting we relieved congestion of the kidney on which the convulsion depended. He always had and always would carry his lancet.

DR. E. M. MOORE, of Rochester, N. Y., contended that we most needed a means of finer diagnosis, and related his experience of epidemics of pneumonia and cerebro-spinal meningitis which occurred in his neighborhood in 1848, when he advocated sustaining treatment instead of blood-letting, in opposition to the general opinions of those days.

DR. POST, of New York City, was in favor of blood-letting in a certain proportion of such cases.

DR. GUNN, of Chicago, also supported such a view, as did also DR. BRIGGS, of Nashville, Tenn., and DR. GREGORY, of St. Louis, Mo.

DR. KINLOCH, of Charleston, S. C., believed that fewer errors were committed on the side of supporting treatment than on that of the depleting method.

DR. DAWSON, of Cincinnati, O., asked why, if blood-letting was such a remedy, have we abandoned it; why, if we advocate a remedy so strongly, do we not use it?

He asked some of the advocates how many times in a year they bled a patient.

DR. NANCREDE made a few corrections of misconceptions entertained by some of the members. He repeated the essential phenomena of inflammations; said he referred only to traumatic inflammation. He did not claim that after tissue changes had occurred the process could be aborted, but, on the contrary, blood-letting after such time had an injurious effect; but that when stasis had occurred, or was beginning, it could be made to disappear, as he had observed. If the heart was weak, he would stimulate it to drive the blood through the part. The good effects were confined wholly to inflamed area.

Paper ordered referred to Committee on Publication.

At Thursday's afternoon session Dr. John H. Packard, of Philadelphia, read a paper containing a report of a reamputation at the hip-joint, secondary hemorrhage with ligation of the primitive iliac artery.

ESMARCH'S BANDAGE AS APPLIED TO TRAUMATIC ANEURISMS.

PROF. T. G. RICHARDSON, of New Orleans, related the following history of a case:

The patient received a pistol-shot in left thigh, October, 1876, in front and to the inner side, four inches above patella, ranging downward, immediately across the track of the femoral artery, emerged at the upper angle of popliteal space, with no serious hemorrhage. The wound healed in a few weeks—no lameness or other discomfort resulted. In April, 1878, the patient discovered a soft deep-seated tumor, which grew for fourteen months, when it had attained the size of a goose's egg. There was no discomfort. But after some time, the limb below the tumor became suddenly one day numb, swollen, and congested, and continued until elevation, frictions, and heat had been resorted to for twenty-four hours.

He consulted his physician in May, 1879, who discovered a fusiform, pulsating soft fluid tumor, a traumatic aneurism, and then placed the patient under Prof. Richardson's care. The patient was admitted to the hospital in New Orleans. The doctor then applied pressure by Esmarch's bandage, fingers, and tourniquet. After seventeen hours, there being no signs of coagulation taking place, and the patient being much exhausted, the treatment by compression was omitted.

A month after, the patient's general condition being favorable, ligation was determined upon. Months after ligation the tumor was still fluid. Dr. Richardson then proposed to aspirate the tumor and close the sac by some stimulating fluid, but the patient, suffering no inconvenience from the tumor, refused instrumental interference, and returned to his usual business. The patient continued well for some time, until December, 1881, when suddenly a most alarming condition arose; the veins of the patient's foot and leg were in a condition of thrombosis, and the skin gangrenous. Amputation was then made, and during the operation the sac of the tumor was accidentally cut, when a profuse discharge of dark bloody-looking fluid occurred. The patient did badly, the flaps after twenty-four hours became gangrenous, and the patient died. An autopsy was made. The tumor measured seven to eight inches in length and four inches in breadth; the artery for two inches immediately above was not obliterated. Above that point the artery was merely a fibrous cord.

The sac did not communicate with the artery below. There projected into the tumor another smaller tumor which communicated with the femoral vein. The doctor then made a summary of the interesting points in the case.

I. *History.*—*a.* Shot-wound, October, 1876. No serious hemorrhage. *b.* Tumor discovered, April, 1878, an interval of eighteen months. *c.* Attention of phy-

sician first called, May, 1879, two and one-half years. *d.* Esmarch's bandage unsuccessful, June, 1879. *e.* Artery ligatured, July, 1879. *f.* Thrombosis and gangrene, necessitating amputation, December, 1881, nearly eighteen months after ligation.

II. *Pathological Anatomy.*—*a.* Expansion of the artery to form the tumor. *b.* Failure of ligation to affect coagulation. *c.* No communication of sac with the artery below. *d.* Nature of the blood in the sac. *e.* Intracystic protuberance and its communication with the femoral vein.

He then exhibited a diagram of the popliteal artery and vein, also the pathological specimen, and asked the assistance of the Association in determining the exact nature of the lesions, expressing himself as in favor of an arterio-venous aneurism.

THE PRESIDENT asked if all the coats of the artery had been traced into the tumor.

DR. RICHARDSON said he had not determined that point.

The papers were referred to Committee on Publication, and a special committee of three were appointed to examine the specimen and report at the next meeting. It was ordered that all discussion of the paper be postponed until after the special committee reported on the return of the specimen.

THE USE OF TRIPHINE IN TRAUMATIC EMPYEMA ASSOCIATED WITH THORACIC FISTULA.

Dr. Richardson also presented the following: Chronic suppurating pleuritis with an imperfect fistulous outlet, external or bronchial, is not an uncommon result of gunshot or other penetrating wounds of the thoracic cavity; and it is no secret that the resources of surgery have not heretofore offered much encouragement to the patients. In the majority of cases there is a contraction or sinking in of the injured side from inflammatory changes, a constant discharge of fetid pus, persistent cough, fevers, and more or less rapid exhaustion of strength, usually terminating fatally. Two main difficulties were encountered in the treatment: first, insufficient drainage; and second, permanent separation of the lung from the chest wall. To those two points he desired to call attention.

First.—The serious obstacle to drainage in these cases was not the stenosis, but the approximation of the ribs consequent upon the sinking in of the chest wall. Owing to the shortness and greater degree of fixedness of the first four or six ribs, very close approach of their adjacent borders was seldom seen except in quite young subjects.

But in other situations where greater latitude of motion existed, more especially along the lateral planes of the thorax below the fifth or sixth ribs, it was not rare, in the cases under consideration, to find the adjacent edges closely applied, and sometimes even slightly imbricated. It was impossible, under such circumstances, by any ordinary means to preserve satisfactory drainage, however extensive it must be made in an intercostal space. The effect of the entrance of air into undrained pyogenic sacs was familiar to every one, and in no other part of the body, not excepting pelvic and psoas abscesses, was the decomposition of the contained fluid more complete or more certain to result in the death of the patient by the production of pyæmia, or more slowly by consuming irritative fever.

Second.—The obstacle to the closure of the pus cavity arising from compression of the lung by inflammatory membrane, and the consequent inability of this organ to expand to its original dimension, was not of itself detrimental to the life of the patient. Pyogenic surfaces when freely exposed to air, and at the same time sufficiently protected to prevent desiccation, more especially if kept moist by an antiseptic fluid, seldom gave rise to pyæmia or irritative fever.

As the great danger in these cases depended mainly

upon the want of suitable drainage, it was to the best method of effecting this purpose that he desired to draw attention. The surgeon's only resort was the removal of a portion of one or more ribs. This might be accomplished by one or other of the ordinary methods of bone-resection, but it may be best accomplished by the use of a large trephine. The idea of trephining the thorax was not new. It was said to have been proposed by Hippocrates, and in more modern times had been modified by Reybard, and adopted by Recamier, Trousseau, and others.

As well as Dr. R. could ascertain, this operation originated in New Orleans, and was almost peculiar to that city, where it had been frequently performed during the past twenty years with increasing favor.

To the late Professor Warren Stone, Sr., M.D., was undoubtedly due the credit of having first performed this or any other method of resection of the rib for empyema.

The Association then adjourned to the amphitheatre of the Ohio Medical College, to witness a demonstration on the cadaver of ligating the primitive iliac artery and the operation of lumbo-colotomy, by John H. Packard, M.D., of Philadelphia, Pa.

DR. B. A. WATSON, of Jersey City, read a paper on

LISTER'S SYSTEM OF ANTISEPTIC WOUND TREATMENT VERSUS ITS MODIFICATIONS,

in which a historic sketch of the developments of the modern method of treating wounds, and a consideration of the effects of the antiseptic treatment was entered into, with a full indorsement of the Listerian method, especially as modified by Dr. Markoe, of New York. The details of several cases were given, showing the advantages of free drainage from wounds, accurate coaptation of surfaces, and the use of carbolic acid solution in suppurating cavities, and their distention.

The discussions were opened by DR. PACKARD, who, on behalf of himself and other surgeons of Philadelphia, repudiated Listerism, had contrived to get along without it, and would continue to do so.

DR. POST, of New York, said the details of Listerism were not followed by himself nor by other surgeons of New York.

DR. A. VANDERVEER, of Albany, N. Y., repudiated Listerism on behalf of himself and other surgeons of Albany, N. Y., but believed that the most important point was thorough drainage.

DR. RICHARDSON, of New Orleans, also repudiated Listerism on behalf of himself and other surgeons of New Orleans.

DR. MCGRAW, of Detroit, Mich., referred to

THE DANGERS OF CARBOLIC ACID,

and related the history of a fatal case, the patient, a boy, dying comatose.

DR. POST asked as to the condition of the pupils.

DR. MCGRAW replied that the pupils were strongly contracted. He was unable to obtain any urine, as the boy passed his urine in bed.

DR. MASTIN, of Mobile, Ala., and DR. CAMPBELL, also spoke against Listerism.

DR. DAWSON thought cleanliness and drainage were the only things to be regarded. Listerism in all of its details had been tried in Cincinnati, but he thought with no better results than without.

DR. NANCREDE still favored Listerism.

DR. PRINCE, of Springfield, Ill., thought Listerism in its details unimportant, but that the principles of Listerism were impregnable.

DR. KINLOCH, of Charleston, S. C., spoke strongly against carbolic acid.

DR. WATSON said that he had not implied that Listerism in its details was accepted by the surgeons of America. He was, in fact, aware that Listerism had made but little progress in the United States, but that it had, nevertheless, a great modifying influence on the treat-

ment of wounds, and that the opposition to Listerism came principally from those who had never tried it or had never seen it.

The Association was again called to order by the President at 10 A.M. on Friday, and went immediately into executive session. The following new members were elected:

Dr. McCann, of Pittsburg, Pa.; Dr. Fenger, of Chicago; Dr. Taylor, of California; Dr. Peck, of Iowa; Dr. Dandridge, of Cincinnati.

THE VALUE OF EARLY OPERATIONS IN MORBID GROWTHS was the title of a paper by S. D. Gross, M.D., I.L.D.

The value of early surgical interference in morbid growths, especially malignant, has long been recognized by writers and teachers, but not with such a degree of force and emphasis to which it is entitled.

The great reasons for the removal of tumors in the early stages of their development may be thus stated: 1, the less risk of shock and of hemorrhage; 2, the more effectual riddance of the diseased structures; 3, the diminished probability of septicæmia, or blood-poisoning; 4, the avoidance of unsightly scars; and 5, the less risk of a recurrence of the morbid action, either at the seat of the operation or in other parts of the body. These propositions are so self-evident that any formal discussion of them seems to be out of place.

The fact is now generally, if not universally, admitted that all morbid growths, whether benign or malignant, are of local origin. There is unquestionably occasionally a hereditary tendency to the development of morbid growths. We see this in a remarkable degree displayed in warts and sebaceous cysts. I state, as another incontrovertible proposition, that all morbid growths, tumors, or neoplasms are the product of perverted nutrition, in which the comparatively few cells native to the part are replaced by colonies of young cells, of the latter of which the new product is essentially composed.

All morbid growths are developed, directly or indirectly, under the influence of inflammatory action, the result of external injury, or, as is more frequently the case, of some mechanical obstruction, causing in the first instance congestion of the part, and this in turn inciting action and inflammation, one of the most simple of all tumors, the sebaceous, is formed under the irritating influence of its own natural secretion, retained by the closure of its natural outlet. Obstruction of a lacteal duct is, there is no doubt, a frequent starting-point of scirrhus of the mammary gland. There are some tumors whose distinguishing features are so well marked, even in their earlier stages, that he who runs may read. On the other hand, great difficulty often presents itself sufficient to perplex and puzzle the wisest head.

Unfortunately few of the cases of malignant disease, either in our rural districts or even in our larger towns, come under our observation in time for early surgical interference. The mischief is effected before the time of observation.

There are comparatively few reliable ready or trustworthy diagnosticians. Diagnosis is a high art, and the profession as a body are not sufficiently familiar with it to render it at all times, or even in a minority of cases, properly available at the bedside. It is, of all the arts in our profession, the one which demands the greatest amount of refined culture, experience and tact of an ordinary type, but of the highest possible type. The one thing most culpable in the organization of some medical colleges is exclusion from its studies of pathological anatomy. Just in proportion as our knowledge of morbid structure is positive, accurate, and comprehensive, will be the probability that we will become skilled diagnosticians, and conversely. Knavery, dishonesty, and self-conceit are found in all ranks of life, and among all classes of men. There are "quacks" in every profession. A patient laboring under a serious morbid growth

may consider himself as peculiarly fortunate if, in the early stage of his troubles, he fall into the hands of an intelligent, upright, and conscientious surgeon. Such a man will not hesitate to express his honest convictions. If the case be beyond his experience, he will not be ashamed to recommend his patient to some other more experienced surgeon, and to lose no time. The knave will do all he can to mislead his patient and lull his fears by telling him his disease is of no importance. He is afraid to tell the truth, lest he lose prestige and thus damage his practice. It is men of this stamp (and their name is legion) that do the damage; ignorant, they allow the case to proceed from bad to worse.

In carcinoma of the breast, the enlightened surgeon does not wait for involvement of the axillary glands, or serious structural disease. He urges the importance of prompt interference. Every surgeon knows what the result of excision of the mammary gland in ordinary cases of cancer is; how rarely the disease is completely removed, and how few women live beyond eight, ten, or twelve months after such interference. In all such cases, cancer cells have invaded the neighboring structures beyond the knife and serve as foci of new neoplasms.

There is a class of patients, the subjects of neoplasms, who, influenced by timidity or mock modesty, wilfully deceive themselves. They are fully aware that there is some disease going on somewhere, but they are afraid to have the matter properly investigated—when they do apply for aid, all that can be done is of the most transient kind. What has been said is true alike of carcinoma, of sarcoma, or even of benign growths. The golden rule in these operations is to perform the work as thoroughly as possible. If this cannot be done it is better in many cases, if not in all, not to meddle with the growth at all. All secondary developments, as enlarged and indurated glands, should be removed in immediate succession. All sarcomatous neoplasms are, as a rule, dangerous formations, however early subjected to the knife, not so much on account of any inherent tendency to recurrence after extirpation, as from their liability to attack other parts of the body from causes similar to those which gave rise to the primary disease. The worst of all sarcomas is the round-cell.

What should be the rule of action of the surgeon in cases in which perhaps several operations have already been performed, there is a large ulcerated surface, attended with excessive pain and a large quantity of the foulest discharge? The only rational thing to be done is surely to sweep away the whole mass of the disease so far as possible, and then treat the wound and the system upon general principles. Such a procedure is the only feasible one of relieving pain, moderating suppuration, and of making the patient comparatively comfortable. Death under such circumstances is generally hailed as a welcome visitor. In malignant disease of an extremity attended by such a state of things, the proper remedy would, of course, be amputation without any ulterior hope of a cure. What has been said respecting early surgical interference in malignant and other morbid growths applies with equal force to many other surgical affections, as well as to diseases in general.

DR. POST referred to the value of early removal of tumors in preventing their degeneration into malignancy.

DR. MOORE said that the principles in the paper admitted of no discussion.

DR. GREGORY remarked that developing cells were more liable to be transferred than the fully developed, large irregular cells, with dry matrix. He said that inflammations were reparative processes; there had always been some antecedent injury; that tumors were the only things to which the word idiopathic could be properly applied. He doubted the propriety of early operations in all cases, and said the success of abdominal surgery in this country was not such as called for early operations. When his patients were useful and not uncomfortable, he put off operating as long as he could. He related a case where

he had delayed the operation for a long time; when he operated, removed both diseased ovaries, and the patient recovered.

DR. NORRIS, of Washington, D. C., then read a paper on

DISLOCATION OF ASTRAGALUS,

and exhibited casts and specimens illustrating the same.

DR. GREGORY had a case of complete dislocation of the astragalus, which was very easily reduced.

DR. WEIST had seen a case of incomplete dislocation of astragalus, of twenty years' standing.

DR. MOORE had seen a case of dislocation, which after persistent efforts was reduced. He had seen two cases with fracture which could not be kept reduced.

DR. DAWSON had a case of simple dislocation, when a young surgeon, which he failed to reduce. He had proposed to divide the tendo-Achillis, which was refused. He thought Dr. Gregory would not meet with another case so easy to reduce when the ligaments were torn; the case was similar to a fracture, but when they were not torn the bone was held firmly fixed in its new position, and reduction is very difficult if not impossible without a cutting operation.

DR. GUNN had not seen a case of simple dislocation, but had had a case of fracture with dislocation forward. No necrosis of the fragment; had made excision with fair result.

DR. P. S. CONNER, of Cincinnati, next read a paper on

EXCISION OF THE TARSUS.

He remarked that the foot, in its proximal half at least, was peculiarly liable to disease. By its situation it was subject to violent jars and severe twists; traumatic synovitis was of frequent occurrence. Its skeleton being principally cancellous tissue and its periosteum blended so intimately with the ligaments of its numerous articulations, and was crossed by numerous tendons, and overlain by a definite though not very thick sheet of connective tissue, inflammations were readily extended by contiguity. In strumous subjects, slight traumas might be followed by simple inflammation, or by deposit of tubercle. Specific periostitis and gumma might produce the same effects here as elsewhere. External violence, compound fractures, might be the cause of caries or necrosis. The disease might affect the whole tarsus; when extensive, rest, compression, stimulant, or sedative applications were very likely to fail. When abscesses had formed and numerous sinuses existed, surgical interference was limited to, 1, opening the abscess cavity and the informal removal of carious or necrosed tissue with or without deep cauterizations or other local stimulant applications; 2, amputation, usually at or above the ankle-joint; and 3, the methodical excision of such and so many of the tarsal bones as were unhealthy. The first method in the less severe cases might be expected to often result favorably. Amputation through the leg or at the ankle joint had been and still was preferred by surgeons generally to any more conservative method, was less likely to be fatal from septic infection or exhaustion, and the patient was better able, with an artificial limb, to earn a livelihood. It was claimed that it might cause death at first, or later that the disease would very likely recur in the parts unremoved, and even if successful as respects life would leave an useless foot, if not one that was an incumbrance.

The three questions to be considered were:

First.—Is excision a safe operation or at least attended with no greater mortality than the alternative amputation.

Second.—Is it likely to put an end to the disease or is recurrence of the disease in the unremoved bones of the foot to be expected?

Third.—Will the patient after recovery from the operation be left with a serviceable foot?

Of the 106 cases collected 11 died (10.38 per cent.),

but two if not three of these died from causes unconnected with the operation within less than a month. Out of 61 cases in which the alternative was an ankle-joint amputation, 4 died (6.55 per cent.), and out of 45 cases in which a middle tarsal removal might have been made 5 died (11.11 per cent.). The Syme and the Pirogoff amputation mortalities for caries were about six to eight per cent., and the Chopart, perhaps, four per cent. While the mortality of the operation in young subjects was very much less, it need not be confined to them alone. Of 77 cases in which the ages were given, 27 were under fifteen years, 1 died (3.7 per cent.); 17 between fifteen and twenty-five years, 1 died (5.88 per cent.); 33 were over twenty-five years, 6 died (18.18 per cent.). The disease recurred in only two cases. The most important question of the three is that in reference to the functional value of the saved foot. Of the 106 operations 10.38 per cent. resulted fatally. Of the 93 cases, the end results of which are known, 10.75 per cent. were failures, 6.45 per cent. left the subjects able to walk with a cane or crutch. In 22.65 per cent., after complete cicatrization, there was no pain or tenderness, little or no limp, and the individuals were able to earn a living; and in 47.31 per cent. the result was so good that the gait was not a bad one, the support of the body was firm, and locomotion was so easy and perfect that the individuals could, without special fatigue, walk long distances. All had a better weight-supporting and useful foot than an artificial foot after a leg amputation could be.

At the Friday afternoon session Dr. E. M. MOORE, of Rochester, N. Y., read a paper entitled

SOME QUESTIONS WITH REFERENCE TO INTRA-CAPSULAR FRACTURE OF THE FEMUR.

The points in the paper were put in the form of questions:

First.—Is not the cause of fracture of the neck of the thigh-bone, whether intra- or extra-capsular, almost uniformly that of a blow upon the trochanter?

Second.—Is not the preservation of the periosteum of the neck called in connection with the reflected capsule, the cervical ligament, although only partial, the common rule and not the exception?

Third.—Does not this condition, if preserved, supply abundant nutrition to the upper fragment sufficient to entire repair?

Fourth.—Is not the outer layer of what is called the periosteum of the neck a rudimentary organ?

Fifth.—In *reputed cases* of absorption of the neck after blows upon the trochanter, said to be without fracture, is it a reasonable, much less a perfect induction to infer a similar result, when the changes of condition are similar in one point, and dissimilar in every other to those of inflammation without a blow?

Sixth.—Should not the induction read thus: The head of the femur and the acetabulum, not being altered, the shortening of the neck could not be from the inflammation resulting from the blow.

Seventh.—Finally, does not the practice of modern surgeons produce a vastly improved result in the cases treated by them as compared with the methods of the last generation?

The doctor then passed some specimens which were taken from patients within a few days after death.

It was ordered, that, as Dr. Senn, of Milwaukee, Wis., had a paper on the same subject, the discussion of Dr. Moore's paper be postponed until after Dr. Senn reads his paper.

DR. SENN then presented his paper, illustrated by specimens. At the conclusion of Dr. Senn's paper, the President complimented both papers very highly, then called for discussion.

DR. POST said the most important principle in these cases was to make no effort by forcible movements to clear up the diagnosis, related a case in his experience

where desire to clear the diagnosis broke up the impaction. Said where at first the shortening was less than an inch, and in the lapse of time becoming greater, until it may be two or two and one-half inches, thought this indicated interstitial absorption.

DR. GUNN then related a case that came under his observation in consultation, where there was the usual symptoms of fracture of the femur within the capsule. The patient recovered with bony union, with some shortening, but was able to walk well with a cane. The limb was measured some four or five years later, with about two inches shortening.

DR. VANDERVEER asked Dr. Senn if he had used the splint which he had exhibited. He also related the history of case, where, the specimen after boiling, there had been as complete separation of the epiphysis of the head of femur as would occur in a subject fifteen years of age, the patient in this case being sixty-five years of age. Thought that better results would follow from the simple treatment of Dr. Moore, than from that of Dr. Senn.

DR. FIFIELD, of Boston, Mass., among other things, said the time for splints was passed. The best results were obtained from position, even in the cases of Colle's fracture this had been demonstrated. He paid a high compliment to Dr. Moore. Related a case where after fracture, the head and neck of the femur had entirely disappeared.

DR. NANCREDE said he had often seen cases where the attachment of the ligament was considerably in advance of its usual attachment.

DR. GUNN said he had seen in a cadaver, a vascular, thick frenum extending from the posterior side of the joint to close up to the head, so that had a fracture occurred, even quite near the head, the upper fragment would have been richly supplied with blood.

DR. KINLOCH, while complimenting Dr. Senn, said that practical surgeons demanded that the advance of pathology must show practical results. He asked if Dr. Senn had demonstrated the practicability of his new methods of treatment upon the cadaver. He doubted if surgeons could make a diagnosis so exact as to cut down upon the neck of the femur and pin the fragments together. He said if Dr. Senn could do this he would admit his pathology, and adopt his methods of treatment.

DR. CAMPBELL thought that practical surgeons ought not to give up their old methods of treatment which they had seen produce good results, for any new methods; not to make a compound out of a simple fracture.

DR. SENN in reply, said he had not tried his modified splint, as he had not yet had a case since making the splint, also in reply to charge of cruelty of his splint, said it was more cruel to treat old patients with this fracture by the old method of confining them to bed, on account of which so many developed disease of lung. Said with his new splint the patients could turn in bed or even get out of bed.

THE PRESIDENT said that eversion of the foot and slight shortening were not reliable symptoms of intra-capsular fracture of the hip. That the eversion may take place from simple contusion, and the slight shortening due to unevenness of the pelvis. He said he could not see in the specimen which Dr. Senn presented as a specimen of impacted fracture within the capsular any evidence of fracture, but that the specimen exhibited only senile changes.

The Association was called to order on Saturday morning by the PRESIDENT. The special

COMMITTEE ON PATHOLOGICAL SPECIMENS

then submitted the following report:

First.—That the original injury consisted of a contusion of the walls of both the artery and vein, with consequent adhesion at the site of injury.

Second.—That the inflammatory processes culminating in the adhesion of the two vessels resulted in such a

weakening of the walls, probably coupled with a limited destruction of the external coats of the vessel by the vulnerating body, as to render an aneurismal dilatation a necessary consequence.

Third.—That the similar probable partial destruction of, and certainly the inflammatory softening of, the venous walls at the joint of adhesion, resulted in a slight pouching toward the lumen of the artery.

Fourth.—That the projection thus commenced, however minute, was acted upon to the utmost advantage by the arterial current, which tended to enlarge the growth by an actual traction and force, as it were, in the direction of the blood-flow; this is proven by the fact that the small sac is elongated on the distal side of the venous opening.

Fifth.—That the projecting venous sac must have served to obstruct the lumen of the artery from the moment of its formation, and have acted somewhat in the way an embolus has been known to do, as the exciting cause of aneurism, by producing undue intra-vascular pressure in an artery with softened walls.

Sixth.—That the obliteration of the lower extremity of the artery which occurred subsequent to the ligation, while an anastomotic branch communicated through the patulous lumen of the artery with the sac, is the cause of the non-coagulation of the sac contents. The apparent paradox that blood can enter into and emerge from a tensely filled sac, is rendered clear when the physical surroundings of the sac are considered. The muscles of the region must have alternately emptied the sac by their compression, and allowed it to refill, when they relaxed. A familiar demonstration of this is the action of the ordinary rubber bulb pipette, although the elasticity of an aneurismal sac is not nearly so great. This deficiency is, however, made up for by the constant pressure of the blood in the patulous upper portion of the vessel, which tended to rush into the aneurism whenever the relaxation of muscle-pressure upon the sac permitted.

Your committee submit the above with some diffidence, in view of the obscurities surrounding any investigation as to the etiology of this case. They feel, however, that while they have not perhaps explained all the facts of the case, their hypotheses more nearly approach a satisfactory solution of the questions involved than any others which have suggested themselves.

CHARLES B. NANCREDE, *Chairman*.
R. A. KINLOCH.

ELECTION OF OFFICERS.

The Nominating Committee reported the following officers: *President*—E. M. Moore; *First Vice-President*—W. W. Dawson, Cincinnati; *Second Vice-President*—C. H. Mastin, Mobile; *Secretary*—J. R. Weist, Richmond, Ind.; *Treasurer*—J. H. Packard; *Recorder*—J. E. Mears.

THE PLACE OF NEXT ANNUAL MEETING

will be Washington, D. C., the Wednesday next preceding the meeting of the American Medical Association.

CLOSURE OF THE JAWS AND ITS TREATMENT,

with the report of a case in which complete occlusion followed a gunshot wound of the left superior maxilla, received at two and one-half years of age, and which was relieved eighteen years subsequently by operation according to a new method, was the title of a paper by J. Ewing Mears, M.D., of Philadelphia, Pa.

Closure of the jaws was well known under two forms—the spasmodic or temporary, and the chronic or permanent. The former occurs with spasmodic contraction of the masseter and internal pterygoid muscles, delayed eruption of wisdom teeth, abscesses, operations on the jaws, etc. The treatment consisted in the removal of the causes. When possible, removal of the teeth. Where tumors, necrosis, and alveolar abscesses exist as causes, the treatment was obvious. In permanent closure of the jaws, we had quite different conditions to deal with. It was due to formation of adventitious tissue,

which firmly and permanently locked the jaws, and in some forms defied successful removal.

The effect of the closure was stated to be a serious interference with mastication and articulation, and if it occur early in life it is often followed by a stunted development of the jaw. With regard to treatment, Prof. Gross stated that ankylosis of the temporo-maxillary articulation might be relieved by forcibly depressing the lower jaw with wedges or levers. In order to prevent reformation of the adhesions, the lever was to be used daily for many months or years.

A résumé of the methods of operation which had been suggested for the relief and cure of permanent closure of the jaws, showed that they had been as follows:

First.—Excision, more or less complete, of the cicatricial bands or osseous formations, and the subsequent employment, for a long period of time, of wedges and levers to retain the separation of the jaws.

Second.—Division of the cicatricial tissues and the adaptation of metal shields, not only to prevent recontraction, but to re-establish the sulcus of mucous membrane at the seat of the alveolus.

Third.—Dieffenbach's method of simple division of the ramus of the jaw, and the formation of a false joint behind the point of contraction.

Fourth.—The formation of a false joint as originally suggested by Carnochan. Esmarch's suggestion that it be formed in front of the contraction; that a segment of bone be removed for this purpose by external incision.

Fifth.—The formation of a false joint in front of the contraction, by simple division of the bone made by forceps applied within the mouth.

Closure due to ankylosis of the temporo-maxillary articulation, the methods practised are:

First.—Division of the ramus of the jaw from within the mouth, either by saw, forceps, or chisel, and the formation of a false joint.

Second.—Excision of the condyle with a portion of the neck, the incision being external.

The reader then related the history of several cases.

DR. MAGUIRE related a case cured by long-continued daily dilatation with instruments.

A PAPER ON REMOVAL OF MECKEL'S GANGLION FOR THE RELIEF OF TRIFACIAL NEURALGIA, WITH REPORT OF CASES,

was presented by DR. VANDERVEER, of Albany, N. Y. While not claiming to present anything new or original, yet the cases seemed worthy to go on record as illustrating the good resulting from operative surgery when medicine has failed to afford the relief sought by suffering humanity. He then related the history of a case which he first saw in May, 1870, where the patient had suffered for over ten years with severe neuralgic pains about the right side of face, along the alveolar processes, and right side of tongue, also in the track of inferior dental nerve. During the preceding five years had been operated upon twice by loosening the attachment of the cheek from the alveolar processes, affording each time a few months' relief to the patient, but the pain returned with as much severity as ever. The patient was very thoroughly treated with iron, arsenic, Brown-Séquard neuralgic pills, injections of chloroform, and every treatment known, but with no especial benefit.

In March, 1871, made a section of the infra-orbital nerve, which resulted in affording great comfort to the patient, who for two years remained quite free from pain. It then returned, more especially along the course of the inferior dental, and suggested the removal of Meckel's ganglion, but his health was such that neither he nor his friends thought it safe. The patient is still alive, and at times suffers great pain for months.

Another patient (female) with about the same history of pain in right side of face, consulted first July, 1875; had suffered more pain since the menopause, two years before. Had but little relief since that time, unless fully

under the influence of medicine. All her teeth of upper right side had been removed, one or two at a time. For last six months but little, if any, relief from pain, even from large doses of the neurotic medicines. Was under the same treatment as the other case.

She consented to an operation to remove the infra-orbital nerve and Meckel's ganglion, which was made September 5, 1875. The patient was immediately relieved from pain, and since that time she has been in perfect health and very grateful.

Another case (female), aged thirty-seven, had suffered with a blind eye on right side. At first had but four or five spasms daily, confined at first mostly to the eye, but there was really no rest for any length of time. She was advised to have eye removed, but refused. After several years she was treated with the usual remedies, but no permanent relief resulted. The spasms became very severe, and returned every few minutes, getting no rest with large doses of morphia, by mouth, hypodermically, etc.

August 2, 1881, after she had had no rest for nearly the whole of the month of July, the doctor consented to remove Meckel's ganglion, but thinking the proper thing to do was the removal of the eye.

For a few days after she suffered occasional spasms of pain, but on the sixth day she was entirely free from them, and slept for the first a quiet sleep. The pain returned in the last week of November, 1881, along the inferior dental nerve, the spasms being very intense, and coming on so rapidly as to prevent any rest. The doctor then tried aconitia (Merk's), but with little, if any, good. She could not bear more than one-eightieth grain doses three to four times daily.

On January 2, 1882, trephined the lower jaw and removed, as I thought thoroughly, a section of the inferior dental nerve, giving almost immediate relief. The pain returned in December, 1882, when a spasm occurred along the lower jaw and outer portion of temporal region. After a time the pain came on as of old, when the patient consented to have the eye removed, which was done April 3, 1883, when the patient, after suffering some pain for ten days, recovered, and still continues fairly well.

TREPHINING THE STERNUM FOR REMOVING FOREIGN BODIES FROM THE ANTERIOR MEDIASTINUM

was the title of a paper read by S. MARKS, M.D., of Milwaukee.

The history was given of a soldier, who was struck on the sternum by a spent bullet (Minié?) during one of the battles of the Wilderness. He was knocked down by the blow. When he recovered sufficiently, he went to the rear, when he was examined by the field surgeon, who assured him that there had been penetration. He was sent from one hospital to another and examined by various surgeons. At last he was sent to one of the hospitals at Washington, which he did not recollect, where he was repeatedly examined by the hospital surgeons, but by others without any suspicion of a foreign body behind the sternum. His condition at this time was such that, fearing he would die in the hospital, he returned to his home in Ohio, where he was mustered out. In the course of time he came under Dr. Marks's and partner's care, with the determination to submit to any treatment that they might advise. The Nélaton probe not answering their purpose, they improvised a probe of the stem of a clay pipe, which was introduced into the wound, passing quite a distance. On removing the probe it showed unmistakable signs of lead. The operation of trephining the sternum was determined upon. When the piece of bone was removed by the trephine, the bullet was found to be a little below the point of operation. Trephine again applied and the bullet, together with the sac which surrounded it, was removed. There was a considerable discharge of pus. The patient, after recovery from the operation, still had some cough, pain, and

shortness. The patient went to work, when one day, after jumping from some elevation, was seized with violent hemorrhage from the lungs. After recovering from the effects of this hemorrhage the patient found himself entirely free from the symptoms before the accident.

On motion it was resolved that the Secretary ascertain which members were opposed to the Code of Ethics of the American Medical Association, and request their resignation.

The Association then adjourned.

Correspondence.

THE TREATMENT OF OPIUM-POISONING WITH ATROPIA—A CRITICISM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In THE RECORD of May 5th appeared an article entitled "Four Cases of Opium Poisoning—Treatment by Atropia and the Faradic Current," by Dr. Wallian, of Bloomingdale, N. Y., which contains a number of serious blunders, either the fault of the writer or printer, but probably the writer. He says, "*four men jointly drank from a bottle four ounces of tincture opii, Phar., 1870.*"

"Asking the druggist from whom the drug had been—with-out fault of his—procured to give me, as nearly as possible, the equivalent in morphia received by each patient, which he stated to be $4\frac{1}{8}$ grs." Now, if the four men drank four ounces of tincture of opium, they took what was together equivalent to more than twenty-four grains of morphia; and if each drank one-fourth of it, they received more than six grains each, according to the Pharmacopœia of 1870. How the druggist was enabled to state that each man took the equivalent of $4\frac{1}{8}$ grains of morphia, while the attending physicians did not know, he does not state. It is not probable that each took exactly the same amount out of the bottle, for, had they been like Western toppers, the last wouldn't have enjoyed any.

Again, he says, "I prepared a solution of atropia, 1 grain to 3 ij., of which I injected subcutaneously ℥xij. (= gr. $\frac{1}{10}$) to each patient." Now it is self-evident that if he gave ℥xij. of this solution of atropia, he did not give $\frac{1}{10}$ of a grain, but twice that amount, or $\frac{1}{5}$ of a grain. Then he says he repeated the dose of $\frac{1}{10}$ of a grain of the same solution; when, again, the patient got $\frac{1}{5}$ of a grain instead of $\frac{1}{10}$, making $\frac{1}{5}$ of a grain.

Next, he says, "recalling the antagonistic ratio existing between atropia and morphia—according to Bartholow to be atropia gr. ss. to morphia gr. j." Now this must be an egregious blunder. Who ever heard of giving a half grain of atropia subcutaneously to antagonize one grain of morphia given by the same method. It is evident that Prof. Bartholow has never written or said any such thing. If so, I have never seen it. But Bartholow, in his work on "Hypodermic Medication," second edition, page 109, says: "I ascertained, in the case which occurred to myself, that one twenty-fourth ($\frac{1}{24}$) of a grain of atropia was equal in toxic power to one (1) grain of morphine," which is a marked difference, and might prove, under certain circumstances, a dangerous one.

Now the writer, not seeming to be satisfied with the two grave blunders he had already made in his two first injections with his unfortunate patient, makes another. He says, "I prepared a solution double the strength of the former one, or grs. ij. to 3 ij. Of this I exhibited ℥xxiv. hypodermically, = $\frac{1}{10}$ grain, to each of the three most under the influence of the narcotic." Here, again, if he gave 24 minims of this solution, he did not give $\frac{1}{10}$ of a grain, but $\frac{4}{10}$ of a grain. Now this could not be an accidental blunder, for in the second solution, which is double the strength of the first, he not only doubles the strength, but doubles the number of minims, first giving xij. ℥; second, giving ℥xxij. He does not seem to be aware that doubling twice is equal to multiplying by four.

Further on in the article he again asserts that Bartholow and other good authorities say that it requires one half-grain of atropia to antagonize one grain of morphia. Now, the doctor not seeming to be satisfied with making a blunder in his arithmetic on each of his solutions, has the audacity to criticise "Bartholow and other good authorities," for he says: "The inference is, that not more than $\frac{1}{10}$ grain, and perhaps $\frac{1}{20}$ of a grain, is sufficient to antagonize one grain of morphia." Who the other good authorities are, he does not state.

Now having scientifically treated his patients by atropia, he "sends for his battery," and applied one pole on the diaphragm, and one on the nape of the neck. He also makes the announcement that "he carefully interrupted the faradic current." He does not state in what manner he interrupted the current, but judging from the rudimentary manner in which the atropia was given, that he probably interrupted it by leaving the sponges on a while and taking them off a while.

The doctor should be congratulated for his heroic courage in a time of difficulty and danger; for few medical men there are who would give atropia solutions hypodermically in cases of narcotic poisoning, when not knowing their strength.

It is fortunate the cases recovered; indeed, the doctor himself seems to be surprised they did so, for in announcing the subject of his article, he says: "Treatment by atropia and the faradic current—Recovery."

The doctor states: "The effects of the antagonist atropia were visible for forty-eight hours or more, as shown by disturbance of vision, unsteady gait, hallucinations, harmless delirium, etc., which would seem to indicate that it was exhibited somewhat in excess of the requirements in the several cases."

This is quite likely, for he gave to each of the worst cases $\frac{6}{10}$ of a grain of atropia, while he intended to give only $\frac{2}{10}$, and $\frac{2}{10}$ and $\frac{1}{10} = \frac{3}{10}$, or, in other words, he gave three times as much as he *thinks* he gave, and then criticizes the authorities for being mistaken on the antagonistic power of atropia.

This is very funny.

C. H. PHELPS, M.D.

EFFECT OF NOISE ON DISEASED AND HEALTHY EARS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The paper by Dr. D. B. St. John Roosa on the effects of noise upon diseased and healthy ears, as reported in THE MEDICAL RECORD of April 28, 1883, is of special interest to those who have it in their own power, from personal experience and observation, to confirm the views therein so ably laid down and defended. The eight aphorisms (l. c., p. 467) are in my opinion invulnerable. There can be no question that, as Dr. Roosa says, there is a large class of people who, though deaf to a considerable degree, hear better and to a remarkable degree of acuteness amidst noises which to those with good hearing are deafening. It appears, however, that all of the observers who deny this fact, as well as Dr. Roosa himself and all of the participants in the debate which followed the reading of the paper, have overlooked an essential fact: the variety of deafness. Simply to say that any one is deaf, is, in our days, to be far from scientific accuracy. *We should define the deafness; state whether the deafness is for high or low tones* as registered by König's rods, or even by the pianoforte or by tuning forks. So far as we yet know, there may be as much difference in the inner ear, under these various degrees of deafness, as there is in eyes affected with hypermetropia or myopia.

The whole question as to hearing, or not hearing, better in a noise, is at present of no really practical value; still, during our investigations we may stumble upon valuable truths. With due deference to those who claim that the deaf do not hear better in a noise, I would

suggest, from my experiments and investigations, a ninth aphorism, to follow the eight as published by Dr. Roosa: Those who are deaf to low tones invariably hear much better in a noise.

J. A. SPALDING, M.D.

SCARLATINAL RASH FROM THE USE OF COPAIBA.—Dr. C. F. Barber, of Fort Hamilton, L. I., sends us an account of the following instructive case: "Not long since a patient came to me suffering from a scarlet rash which completely covered the body, leaving a space hardly the size of a pin's point free. He complained of intense itching and burning sensation about the skin; the right hand was puffed up, the left normal in size. His mouth and throat were tender, compelling him to eat only fluid food. Nausea, but no vomiting, headache and a languid feeling were present. The eruption would disappear on pressure, but instantly return as soon as the pressure was removed. On close questioning the patient admitted that about one week previous he had contracted gonorrhoea, and had obtained a prescription, as is so often done by the young men of the present day, from a druggist, the active principle of which was balsam copaibae. This he had used faithfully until he came to me; time being just seven days. Being a strong and healthy young man, never having had any disease, save the present attack of gonorrhoea, I could see no other cause for his rash and at once stopped his recipe, and placed him upon another course of treatment. As soon as the copaiba was discontinued he began to improve and the rash soon disappeared."

ON THE OCCURRENCE OF TUBERCLES IN WHICH THE BACILLUS TUBERCULOSIS IS NOT DEMONSTRABLE BY THE ORDINARY METHOD OF STAINING.

By T. MITCHELL PRUDDEN, M.D.,

DIRECTOR OF THE PHYSIOLOGICAL AND PATHOLOGICAL LABORATORY OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; LECTURER ON NORMAL HISTOLOGY IN YALE MEDICAL COLLEGE.

ALTHOUGH more than a year has passed since the announcement by Dr. Koch of his hypothesis of the bacterial origin of tuberculosis, and the long and logical series of experiments on which it is based, it is still in the main in nearly the same condition as that in which he made it known. Numerous of his confirmatory data have indeed been found to stand the test of careful scrutiny by skilled observers, and have been greatly strengthened, while in some respects modified, by the record of the examination of an almost incredible amount of material. The additions and confirmations, however, belong almost entirely to that side of the problem which is least essential for the establishment of the new pathological doctrine, although of the utmost importance from the standpoint of diagnosis, and possibly of prophylaxis and treatment. The more extended researches of the past year have shown that the examination of sputum is of much more practical importance than the original announcements gave reason to expect; that the technique of sputum examination for the bacillus tuberculosis must become a part of the professional furnishing of every expert diagnostician, whether the bacilli stand in a causative relation to tuberculosis or not, and that to be reliable considerable skill and much patience must be exercised; that the color-test must be subjected to some limitations not anticipated in the original announcements, because some other bacilli and many other objects are found to present the coloration originally supposed to belong to the tubercle bacilli alone; and finally, that the decoloration by nitric acid in Ehrlich's method of staining may result in the complete removal of color from some of the structures which it is desired to demonstrate, unless the greatest care be exercised, and possibly even then, since the conditions which modify their power of resisting the action of the acid are not yet definitely known.

Dr. Koch, in his recent reply to his critics,¹ deplors the fact that in the eager search for data of an immediately practical nature the more essential character of the cultivation and inoculation experiments should have been apparently lost sight of. While the whole world stands agog to know whether the tubercle bacilli are to be found in each particular specimen of sputum, feces, and urine, or on all tubercular ulcers, or in every phthisical cavity, or miliary tubercle, or cheesy nodule, his fundamental hypothesis remains unconfirmed; and he complains, if a little querulously, still it must be confessed justly, that the criticisms of his hypothesis and his statements, which have thus far been made, are not based upon experiments executed with sufficient care and data, gathered with sufficient clearness of perception as to their applicability to the question, to afford him much satisfac-

tion in framing a reply. This condition of affairs is, however, not at all surprising, for, apart from the circumstance that the immediately practical bearing of the subject appeals to by far the greater proportion of men in the profession, the careful working over of the ground so elaborately covered by Dr. Koch's experiments, by professional pathologists, would require not only abundant and exceptional facilities, but a devotion to pure science which must far exceed that of Dr. Koch himself, since the stimulus of the pioneer would be largely wanting. Still, the immense amount of exhausting labor bearing on the simpler morphological side of the problem, which in this short time has been done by men for the most part busy in the practical exercise of their profession, leads to the hope that ere long some man may appear happily enough circumstanced, and richly enough endowed with patience and acumen, who will either furnish the needed confirmatory evidence, or show himself—to fall into language by which alone the present belligerent attitude of some of the workers and more of the writers in this field can be indicated—a foeman worthy of Dr. Koch's steel.

In the meantime the simple examination of tubercular lesions and various excreta are leading to fairly definite conclusions in some of the accessory fields. It is already practically established that in the larger proportion, if not in all cases of phthisis in which there is evidence of the breaking down of tuberculous tissue, and in many cases in which physical signs are entirely negative, the tubercle bacilli may be found in the sputum, if sufficient care and patience and skill be exercised, and that they do not occur in non-tuberculous sputum. It is further demonstrated that the bacilli may be found in the feces in many cases suffering from tubercular ulcers of the intestine, and in the urine in some cases of tuberculosis of the genito-urinary tract. It is furthermore proven that the examination of material from the surface of tubercular ulcers of accessible respiratory passages may often determine their specific character. While at present of much practical importance, rapidly accumulating data lead to the belief that increased definiteness in the estimate of the value of such examinations may be confidently expected.

It is furthermore established, that in the great majority of phthisical cavities in the lungs, the contents and walls contain the bacilli in greater or less numbers; that the tuberculous areas and miliary tubercles in acute and chronic phthisis, many of them, contain bacilli; that in most cases of acute miliary tuberculosis the bacilli are present in many or most of the nodules. But it is equally true that in many of the miliary tubercles and cheesy areas, and in diffuse tubercle tissue in acute and chronic phthisis, and in some of the tubercles in acute miliary tuberculosis, the bacilli cannot be demonstrated by the technical procedures at present at our command. It was shown in a previous paper by the writer,² and confirmed by two new examples about to be recorded, that there are cases in which over large tracts crowded with miliary tubercles, both cheesy and in the earlier stages of growth, no bacilli could be detected by the most exhaustive search. Since the publication of the paper just alluded to, the lungs of a considerable number of new cases of acute and chronic phthisis have been examined, with essentially the same result, namely, that in and about all

¹ Deutsche Med. Wochenschr., No. 10. March 7, 1883.

THE MEDICAL RECORD, April 14, 1883.

cavities, in many of the larger areas of coagulative necrosis, and in a considerable proportion of the miliary tubercles, the bacilli are to be found in varying numbers. But in nearly all cases some of the larger cheesy areas and the tubercles, particularly those which were not cheesy and were in an apparently early stage of development, presented no bacilli by the same methods of staining and care in examination which revealed them in other parts. This result is in harmony with the observations of nearly all those who have made and studied extensive series of sections from tuberculous organs.

Two cases, however, formed such marked exceptions to the rule that they seem worthy of a special record. J. R.—, aged forty-seven, Irish, states that his health was good up to four weeks before admission; he then first noticed swelling of the legs and face. He soon began to suffer from cough and dyspnoea, with vomiting, occasional headache, and constipation. On admission patient had general anasarca to a moderate degree, dyspnoea was intense, cough slight, temperature $100\frac{3}{4}^{\circ}$, pulse 86, urine specific gravity 1.010, varying in quantity from thirty to ninety ounces, and containing albumen and casts. Fluid was found in left pleural cavity below angle of scapula. Aspiration resulted in the removal of a few ounces of bloody fluid. Immediately after the operation patient had a severe chill, and developed lobar pneumonia in right side. The dyspnoea continuing severe, aspiration was repeated, forty-eight ounces of bloody serum being drawn off. He grew steadily weaker, and died about four weeks after admission.

Autopsy.—The right lung was partly bound to the chest wall by old adhesions, and the entire lung was in a condition of gray hepatization. The left pleural cavity contained about one hundred cubic centimetres clear yellow fluid, and the lung was partially and loosely bound to the costal pleura by thin, partly organized adhesions. The lateral surfaces of both lobes were covered by a thin, delicate pellicle of organized membrane, thickly studded with small miliary tubercles. Neither tubercles nor cheesy degeneration were found in any other part of the body. The kidneys presented the lesions of chronic diffuse nephritis. The mucous membrane of the stomach was thickened, and the liver slightly infiltrated with fat. The other organs were normal. Many of the tubercles, as seen in sections, stained double with hematoxylin and eosin, consisted of sharply circumscribed collections of small spheroidal cells; most of them, however, were of the usual giant-celled and epithelioid-celled type, with a more or less well marked reticulum. In none of those examined was there well-marked cheesy degeneration. Six hundred and ninety-five sections, about .01 millimetre in thickness, were made from ninety-nine different tubercles from various parts of the tuberculous membrane, and stained in the usual manner by Ehrlich's method in several different lots. In not one of these six hundred and ninety-five sections could a single tubercle bacillus be detected, although all were examined with the most scrupulous care, and in many specimens the examination was several times repeated.

This case, together with one of acute general miliary tuberculosis in a child, and one of primary tubercular inflammation of the bladder, ureter, and kidney, already recorded, makes a series of three exceptional cases, observed by the writer, in which, although judged by anatomical criteria there could be no doubt of the character of the lesion, the structure being in each case perfectly well defined, no bacilli could be detected in the tubercles in any part of the body.

The following case presents a condition of affairs still more noteworthy. The man was an Italian, aged fifty-two, a ragpicker. He stated that he was perfectly well up to two weeks before admission, when he first noticed a swelling of the abdomen, and he soon began to experience nausea and vomiting. He suffered from considerable abdominal pain and dyspnoea, was unable to retain food in the stomach, and rapidly lost flesh and strength.

On admission the patient was much emaciated, cachectic, pulse feeble, dyspnoea marked, abdominal pain severe. There were a few subcrepitant râles over both apices in front and behind, considerable ascites preventing satisfactory examination of abdominal organs. He refused to take food, was sleepless; the dyspnoea and abdominal pain continued; he became weaker and delirious, refused all attempts to relieve his ascites, and died, apparently from exhaustion, twelve days after admission. The temperature was at no time above the normal.

Autopsy.—Abdominal cavity contained a large quantity of clear yellow fluid with fibrinous flocculi. Bands and membranes of fibrin bound the abdominal wall loosely to the intestines, and bound the intestinal coils firmly together. Nearly the entire surfaces of the intestines, liver, under surface of the diaphragm, and a large part of the parietal peritoneum were thickened and very thickly studded with white, slightly elevated nodules, varying from one to three millimetres in diameter.

The omentum, converted into a dense nodule or cylindrical mass, lay along the transverse colon, and extended down in a solid cord to the right inguinal region where it was attached to the abdominal wall. Heart normal, left pleural cavity contained about one litre of clear yellow serum, which crowded the otherwise normal lung inward and backward. The right lung was firmly bound to the chest wall by old thick adhesions, and the costal pleura was considerably thickened and sparsely studded with dense white and gray nodules about two millimetres in diameter. In the thickened pulmonary pleura, and in the lung tissue immediately beneath it, were a few scattered, dense, somewhat stellate nodules, similar in appearance to those in the corresponding thickened costal pleura. At the apex of the right lung, and confined to an area of about six centimetres in diameter, in either direction, were several dense grayish pigmented bands of connective tissue and larger and smaller hard branching nodules. One of these nodules, about one centimetre in diameter, was cheesy at the centre, and another, somewhat larger, contained a small cavity filled with disintegrated cheesy material. This cavity did not communicate with a bronchus. The bronchial glands were enlarged, deeply pigmented, and studded with small white nodules. The other internal organs were normal. The mesenteric glands were not enlarged. The anatomical diagnosis was accordingly old chronic phthisis at apex of right lung, with pleurisy and chronic miliary tuberculosis; left hydrothorax; tubercular peritonitis.

Microscopical examination by the ordinary hematoxylin and eosin staining showed the small scattered nodules in the surface of right lung, in the thickened costal and pulmonary pleura, and about the consolidated areas in the apex to have the ordinary structure of fibrous tubercles, many of them much pigmented at the centre. The larger nodules at the apex were composed in part of dense pigmented connective tissue, in part of areas of coagulation necrosis, with a peripheral zone of tubercle tissue. The wall of the small cavity was formed of shreds of necrotic tissue, of dense cheesy material, and in the outermost layers of tubercle tissue and ordinary dense connective tissue. The examination of a large number of thin sections from these various forms of nodules, stained by Ehrlich's method, showed that the tubercle bacilli were abundant in the walls and edges of the cavity, and in a few of the dense areas of coagulation necrosis in its immediate vicinity. But in the diffuse tubercle tissue, in the zones of simple pneumonia around the nodules, in the scattered fibrous tubercles in the lung and pleura, and in the well-formed tubercles in the bronchial glands no bacilli could be found.

Microscopical examination of the nodules in the serosa of the intestines, diaphragm, liver, and abdominal wall, as well as those in the thickened omentum, showed them to be miliary tubercles presenting the usual variations in structure; most of them were more or less cheesy at the centre and of the giant- and epithelioid-celled type,

but many were of less complex structure, consisting simply of circumscribed collections of small spheroidal and epithelioid cells lying in and upon the thickened serosa. Nine hundred and nine sections from a large number of these peritoneal tubercles, from different parts of the affected surfaces, stained by Ehrlich's method revealed, under the most searching scrutiny, no tubercle bacilli. Among the numerous tubercles chosen for examination, four, each of about one millimetre in diameter, were completely cut into sections of about one-eightieth millimetre in thickness. This exhaustive examination of single tubercles was made to reduce the possibility of error which the examination of a few sections only from various tubercles necessarily involves. Not a single bacillus, however, was anywhere detected.

Here, then, is a case of chronic phthisis in which, judging from the clinical history and the anatomical appearances, the morbid process was apparently for the most part at a standstill, but in which the tubercle bacilli still remained in a small cavity and in a few cheesy areas in its immediate vicinity at the apex. Upon this condition of affairs in the lung the more acute tubercular peritonitis presumably supervened. Judging from the considerable thickening of the peritoneal serosa in and upon which the tubercles lay, the process here was of longer duration than the somewhat meagre clinical history would seem to indicate; but the structural characters of many of the tubercles, on the other hand, would favor the belief that their development was actively occurring.

The general features of this case would lead to the expectation that it would furnish a most exquisite example of auto-inoculation, and the popular conception of Dr. Koch's hypothesis would demand that the bacilli should be found in the peritoneal tubercles, particularly in those of presumably recent development. They could not, however, be found in any of the forms. But the writer is inclined to believe that the popular conception of Dr. Koch's hypothesis is not altogether correct. That the presence of the bacilli in each and every miliary tubercle, especially of younger form, must be demonstrable or the hypothesis is greatly weakened, is a notion founded in a misconception of the broad nature of his fundamental propositions. That tuberculosis is an infectious disease; that it can be communicated by the inoculation of the so-called bacillus tuberculosis, presumably freed by cultivations from all contaminating substances, and that this bacillus is the sole cause of the disease—these are the main features of his proposition. For Dr. Koch the criterion of a genuine tubercle lies in its infectious nature, and not in its anatomical character. Whether this criterion be accepted or not is at present a matter for individual decision, at any rate, it is a logical assumption as based on the data adduced by Dr. Koch. That the very frequent occurrence of the bacilli in the lesions of tuberculosis, in the human subject and in the victims of experimental inoculation, is a valuable confirmatory fact, there is no doubt, but so far as the writer is aware Dr. Koch nowhere states, nor does the establishment of his hypothesis require that the bacilli should be, or should have been bodily present in every tubercle.

The fact that in cases of phthisis and acute miliary tuberculosis some of the tubercles do not, as judged by our present technical procedures, seem to contain bacilli, and that some apparently exceptional cases of tuberculosis do not reveal their presence anywhere in the body may be explained, it should be remembered, either, first, by the possibility that the parasites after inaugurating the morbid process may disappear from the seat of lesion or from the body; or, second, by the faulty nature of our demonstrating them; or, third, by the possibility that the bacilli may induce the growth of tubercle tissue in distant parts of the body by some product of their physiological activity at present entirely unknown to us; or finally, by the not improbable hypothesis that the morbid process which we call tuberculosis, may be induced by more than one agent.

It may be that it is just such a criterion as that which Dr. Koch asserts which we need to supplement the anatomical classification of tubercle-like growths with which, with no end of bother, we have perforce made shift to be content so long.

These apparently exceptional cases, while enigmatical, are interesting and may be of much importance at a later stage in the elucidation of the problem, but the writer does not at all believe nor would he willingly convey the impression that they are necessarily of much significance as bearing upon the parasitic character of the disease. Whether such tubercles as do not seem to contain bacilli would produce the disease if inoculated is a question which, however difficult, it may be necessary to answer when the limitations of their occurrence have been more definitely established. In the meantime it is important to avoid the error of adopting a more precise conception of the exact way in which the bacilli exert their influence, if they do so at all, upon cell-proliferation and the formation of tubercle tissue than our actual knowledge of the conditions and phenomena of cell life and the natural history and physiology of the bacillus tuberculosis will fully justify. Into this error it seems to the writer that Dr. Cheyne, the author of the "Report to the Association for the Advancement of Medicine by Research on the Relation of Micro-organisms to Tuberculosis,"¹ falls, when, after stating the indisputable fact that the tubercle bacilli are very often found associated with the epithelial cells formed in tuberculosis of the lung, he assumes that the new epithelioid cells are largely, if not entirely, due to the proliferation of alveolar epithelium, and further, that this proliferation is due to the direct stimulus of the presence of the bacillus tuberculosis. "The bacilli," he says, "escape from the blood-vessels or lymphatics and get into the alveolar epithelium, where they grow and cause multiplication of the epithelial cells till the alveolus becomes completely filled with these cells and infiltrated leucocytes." Furthermore, the whole process is detailed with the most pleasing clearness as follows: "The tubercle bacilli, which reach the lung by inhalation, develop in the epithelial cells lining an alveolus, this alveolus becomes filled with cells, neighboring alveoli become infected, and the same process goes on in them. The further result will depend on the number and rapidity of growth of the bacilli and on whether the patient is a good soil for their development. If they develop well we have curious pneumonia, if they grow slowly and with difficulty we have fibroid phthisis."

Now this may all be true, but the expression of a personal conviction, however strong, does not do away with the necessity for proof, and the fact that large quantities of the same epithelioid tissue may be found in every case of cheesy pneumonia and in many cases of chronic phthisis unassociated with the bacillus, and that the same increase in epithelioid cells is common in various forms of pneumonia not tuberculous, suggests at least the desirability of caution in explaining the cause of such results.

It is by no means easy, in the present state of our knowledge concerning the life history of nearly all forms of cells, to be certain as to the exact origin of new cells produced in the body in disease; witness the long series of patient researches which have not yet led to such positive results as could be wished regarding the respective rôles of connective tissue and white blood-cells in ordinary inflammation. And when to the inherent difficulties of the problem of the origin of new cells in general in disease we add the complexities which the introduction of a vegetable parasite whose natural history and physiological phenomena are almost entirely unknown, it is not by any precise conjectural rationale, however plausible it may be, that this obscure and difficult field of pathology is to be illuminated.

¹ Practitioner, vol. xxx., No. 4, April, 1883.

The much talked of refutation of Dr. Koch's hypothesis by Spina¹ is couched in so unscientific a spirit and rests upon so flimsy a basis of actual experiment, that it seems scarcely possible that it should for more than a moment be permitted to have any influence whatever upon the question. The admirable study by Dr. Cheyne, above alluded to, is very valuable, so far as the experimental data go, in confirming many of Dr. Koch's statements, but it seems to the writer to lack independent and objective character and not to embody researches extensive enough to give it the weight which must belong to that series of investigations which alone can give to the new hypothesis the position in science which it claims. So our attitude in regard to the primary hypothesis must, it would seem, still be one of expectation.

As the appearances and importance, from the diagnostic standpoint, of the tubercle bacillus become more and more familiar to the practising physician, as they are unquestionably destined to do, it is very essential that it be clearly understood that its occurrence in sputa and other excreta in tuberculosis, however constant or practically valuable as a means of diagnosis, is not in itself a proof of the parasitic origin of the disease, nor does the search for it commit the observer in the least to the germ theory. For as far as all this goes it may be merely a harmless concomitant of tuberculosis and nothing more. When once it is proven beyond reasonable doubt to be one of the causes or the sole cause of tuberculosis in man then will arise questions in prophylaxis and therapeutics second in importance to none which can engage the attention of medical men.

From the immediate practical standpoint, knowledge is most urgently needed on the subject of the occurrence of the bacilli in the sputa and other excreta in acute miliary tuberculosis, both in adults and children, and on their occurrence in cases of primary hæmoptysis and in the incipient stages of various forms of phthisis, as well as in cases in which complete recovery has occurred or in which the disease has become latent.

Finally, a searching examination of the reliability of the technique of the bacillus-staining is urgently needed. Ziehl² has shown that the nitric acid employed for decolorizing may, if permitted to act too long, entirely remove the characteristic color from the tubercle bacilli and so permit them to escape detection, and, furthermore, that marked differences exist among the individual bacilli in the same specimen as to their power to resist the decolorizing action of the acid. He has shown, moreover, and this has been abundantly confirmed by the researches of others, that it is not at all necessary to employ nitric acid for differentiating the usual. If after staining the specimen with fuchsin in the usual way it be placed in some other anilin dye, *i.e.*, methylin blue, the latter stain will displace the red color from the animal cells and other bacilli before it will from the bacillus tuberculosis, and if the operation be stopped at the right time a differentiation in color may be obtained not less marked and less liable to errors than that obtained by Ehrlich's method. The writer made use of this method for controlling the examination of the exceptional cases above described, but with the same result.

Dr. Cheyne³ avoids the use of nitric acid, apparently because of the unavoidable shrinkage which it occasions in the tissues, by the employment of the following method. Stain first with fuchsin; wash in distilled water; put for a moment in alcohol and then place the specimen for from one to two hours in the following solution: Distilled water, 100 c.cm.; saturated alcoholic sol. methylin blue, 20 c.cm.; formic acid, 10 M. It is then washed with water and treated with alcohol and oil of cloves in the usual way. Acetic acid may be used instead of the formic, but is required in somewhat larger quantity.

SPINA BIFIDA.

A SUCCESSFUL OPERATION AFTER THE METHOD OF MR. ROBSON, OF LEEDS, ENGLAND.

By ROBERT T. HAYES, M.D.,

ROCHESTER, N. Y.

THE MEDICAL RECORD for February 10, 1883, quoting the *British Medical Journal* for December 30, 1882, reported a case of spina bifida operated upon successfully after a new method, by Mr. Robson, of Leeds, England. Following the points laid down in that report, a similar case was treated here by the new operation on February 21st.

The patient was a female, aged nine and a half weeks; general condition good. The tumor, situated in the lower dorsal region, was the size of one-third of a hen's egg at birth, and more than twice that size at time of operating. Pressure during the first two weeks after birth seemed to stimulate the growth of the tumor, and was abandoned on account of the irritative symptoms induced. Fluctuation could be very distinctly and readily produced with one hand over the anterior fontanelle and the other over the tumor.

The child, anaesthetized by chloroform, was laid over a pillow on its face; the object being to limit, by gravitation, the loss of cerebro-spinal fluid. The attempt was first made to remove a part of the fluid by means of aspiration; but after some five to six fluidrachms were removed, the fluid having all the characters of pure and normal cerebro-spinal fluid, no more could be obtained by repeated punctures. The skin was then incised and a layer of adipose tissue met with of about one and one-half inch in thickness. This being dissected back on each side, a double sac was found; an external one, collapsed, not communicating with the spinal canal, and from which the fluid was obtained; and under this a true sac, formed by protrusion of the membranes of the cord. The aspirator needle was introduced through the thinnest portion of this sac, when the patient instantly collapsed. During some fifteen minutes spent in efforts at restoration, sufficient fluid oozed through the puncture to leave the sac somewhat flaccid as the child lay. The needle was then reintroduced, some ten fluidrachms more removed, and the sac then freely opened. The spinal cord appeared perfectly normal, and on either side was seen the root-fibres of two spinal nerves, terminating abruptly at the inner surface of the base of the sac. The superfluous portion of the membranes was then removed, and union formed by six interrupted catgut sutures. While the periosteal grafts were being prepared, the patient was accidentally brought nearly into an upright position, when, with a free gush of fluid she again, and very profoundly collapsed. After partial restoration was with much difficulty brought about, some twenty small grafts of fresh periosteum from a rabbit were introduced on the surface of the membranes and the external flaps, fatty tissue and all, hastily trimmed and closed. The patient was extremely exhausted, and only rallied after some hours of active stimulation, and maintenance of a low position of the head; any approach to the horizontal, much less upright position inducing fainting.

After rallying, recovery was rapid, kind, and perfect. Simple cold water dressings were used. Surgical fever reached 102° F. within six hours, and ceased entirely within twenty hours. Union occurred throughout the wound by first intention, at all but one point. Here a sinus existed, through which clear serous fluid drained very freely, certainly to the extent of several fluidounces daily, for four or five days, and then more and more sparingly until the tenth day, when the sinus at once closed. At no time was there any appearance of pus about the wound.

The present condition of the child—more than eleven weeks after operation is this: She is stronger, larger, brighter, and more contented than any of her preceding brothers or sisters have been at her age, and suffers ab-

¹ Studien über Tuberculose. Wien, 1883.

² Zur färbung des Tuberkelbacillus. Deutsche Med. Wochenschr., viii., 451. Berlin, 1882.

³ Loc. cit., p. 258.

solutely no obvious inconvenience, except a mechanical one from her deformity. The tumor is about one-half the size it was before operation, but the most careful examination fails to reveal anything more than fatty tissue in it. Under this can be distinctly felt a covering over the opening in the spinal canal, which is, to use Mr. Robson's words in describing his result, "of much greater than mere skin hardness." The tumor is no more sensitive than other portions of the skin, and reasonable pressure fails to affect in any degree the tension of the fontanelle.

I would add to Mr. Robson's points in operating: First, care in removing a portion of the fluid in the tumor before free incision, as a guide to the degree of tolerance present in each case for such a procedure; second, the careful maintenance throughout the operation and for some time after, of such a position of the patient as will most favor the retention by gravitation of the largest amount possible of cerebro-spinal fluid.

Finally, I would remark the apparent confirmation of the successful and useful application of periosteal grafting in this operation.

ENDEMIC DISEASES IN FLORIDA.

By C. DREW, JR., M.D.,
JACKSONVILLE, FLA.

In February, 1881, I began a systematic study of the endemic diseases peculiar to East Florida, having had compact blank forms printed to fit into my note-book, so that at the bedside of each patient could be obtained and recorded the date of attendance, sex, age, color, disease, residence, time of residence in the State, result, etc. My object was to ascertain for each month the per cent. of disease due to malaria, the per cent. of cases of fever in non-residents, per cent. of cases of phthisis occurring in residents, or any other facts which might be brought to light; also the mean barometer, thermometer, humidity, and direction of winds for each month. The question is often asked, "What are your most sickly months?" and although we well know that September and October are most insalubrious, it occurred to me that it might lead to some useful results to study the subject more accurately, and obtain in figures the exact percentage due to malarial influence, and at the same time to ascertain the meteorological statistics in order to consider their bearing upon such facts. Meteorological and topographical conditions undoubtedly often act in concert to induce disease, and although we can do nothing with the former, we may so change the latter as to produce, under similar circumstances of wind and weather, very much better conditions. The figures, it must be admitted, are few in number, and a larger record might perhaps lead to somewhat different results, but it is perhaps a fair average of results to be obtained under our usual climatic influences. Very accurate results could be obtained, in studying disease in its relations to meteorological changes, by making daily observations of both, ascertaining the prevalence of a certain type of disease and its relations to such changes upon each particular day, and if any value could accrue from such study, it would be much enhanced if such observations could be made by a number of observers, daily results being handed to a compiler for summarizing—in other words, "the collective investigation of disease," as recently suggested by the British Medical Association. Their method is to "draw up cards and explanatory memoranda regarding certain diseases, such as chorea, rheumatism, etc. These are sent to each member of the association, with the request that he answer the inquiries and return the cards to the secretary." A majority of cases recorded were within the limits of the city of Jacksonville, the semi-insular situation of which (being partly surrounded by creeks with marshy borders) makes it a good index of the influence of winds in wafting the germs of malarial disease from certain quarters into the habitations of

man. During the last two years the marshy margins of the creeks surrounding the city have been partially reclaimed, which, I believe, has made a considerable reduction in the amount of malarial disease prevalent in the suburbs.

The accompanying table exhibits the fact that the greatest percentage of such disease existed when the winds blew from the northeast or southwest, and as the greatest areas of marshland lay in these directions, it is more than probable that the germs of disease were wafted from them into the residences of those living in the vicinity. Only for the month of March is the wind reported as having blown from the west, and during that month the number of cases of disease due to malaria is very small—15.42 per cent. In February but few cases are on record, as I had just returned from the North and my practice was small. In this month, although the temperature was 58°, the percentage of fever cases was 25 while the wind blew from the northeast, while in March, when the wind came from the west, the percentage was only 15.42, with a temperature of 60°. All things being equal, the nearer we approach the freezing-point the less liable we are to malaria. At this point it is not likely that winds exert any modifying influence, but up to that point I would infer that they did.

Dr. Austin Flint, in his work on "Practice," speaking of malaria, proposition third, states: "Its evolution or active agency is checked by a temperature of 32°;" which proposition is fully endorsed, I think, by the experience of the profession. In proposition fourth, written in 1867, he states: "It is most abundant and virulent as we approach the equator and sea-coast." It now becomes a

question as to whether or not conditions have changed, as severe cases of malarial disease have recently been reported from New York (even in that famous health-resort, the Catskills), from Connecticut, and my conversations with intelligent observers from Western States lead me to think that their malarial fevers are more intense than those observed in East Florida. My experience would lead me to infer that malaria in this section is much less intense than it was a few years ago. I am almost certain that within the last decade cases of pernicious fever are much less common than formerly. One case of chronic malarial cachexia is recorded in January, 1882. As an evidence of the scarcity of such cases in East Florida may be mentioned the infrequency of enlarged spleen. I have heard this fact commented upon by gentlemen of experience who have moved to this section from other portions of the State.

From the table it would appear that the percentage of disease due to malaria is large, but to offset this the sequelæ very seldom imperil life or future health, being easily remedied by a temporary change of climate, or in nearly all cases by time and proper remedies at home. The mortality is small, presenting a marked contrast to diphtheria and scarlet fever of the North and West, both of which are very fatal, followed by troublesome sequelæ, and are said to be upon the increase. The table exhibits a total of two hundred and twenty-eight cases of malarial fever for the year, including one recorded as typho-malarial, out of which there were six deaths, or 2.64 per cent. In estimating the per cent. of cases due to malaria all those residing in the State under one year are regarded as strangers.

The smallness of the percentage for December, January, and February, months when the city is replete with strangers, is remarkable. In March also it is small.

The total number of cases of phthisis recorded for the year as having developed among residents is fifteen, giving a percentage of morbidity of 3.4; it is impossible to offer any statistics as to the mortality from this disease in so brief a period of time. There does not appear to have been any remarkable relation between barometrical pressure and the existence of disease. From February to September, with the gradual rise of temperature incident to the summer months, the percentage of malarial disease increases. Through September, October, and November, although the temperature declines, the rate increases, and keeps up until January, when it becomes quite low. Mean humidity does not appear as a prominent factor in the development of this class of diseases. The lowest mean humidity is reported for March, when the percentage of malarial fever is low, 15.93, but in January, 1882, when the mean humidity was 78.8°, a high degree, the percentage of fever was low, 21.42. The meteorological observations were copied from those issued by the signal service at this station.

CHLOROSIS AND FEVER.—The temperature of ordinary cases of chlorosis met with in young women is usually believed to be normal. This belief has been contested by Dr. Mollière, in a paper contributed to the *Lyon Médical*. His observations were made on eight young women, who presented no other signs of disease beyond the anemia for which they were under treatment. The temperature was taken every morning and evening in the rectum, over a period varying from two to fifty days, and was found to oscillate between 101.8° and 102.8° F. The amount of urea eliminated per diem was estimated and found to be normal. Mollière suggests that the increased heat may be explained by the hypothesis of a combustion, the products of which are not so easily recognized as urea. Sulphate of quinine was given as an antipyretic, with the effect of reducing the temperature temporarily. This effect, if constant, would, according to Mollière, definitely establish the existence of abnormal body heat in chlorosis.

Progress of Medical Science.

THE BIOLOGICAL ACTION OF PICTROTOXIN.—Professor Chirone, of the University of Padua, published last year his experimental researches on the biological action of cinchonidin. He found this alkaloid was capable of producing a true artificial epilepsy. By means of many vivisections he was able to demonstrate that cinchonidin exercises its action on the cortical motor centres of the brain; since, when the cerebral hemispheres in pigeons were removed, the epileptogenic action was wanting; when one cerebral lobe only was removed, cinchonidin caused an epileptic convulsion only on the half of the body in relation with the psycho-motor centres not removed.

Picrotoxin also is able to produce epileptic convulsions. Professor Chirone now publishes the results of his experiments with picrotoxin, undertaken with the aid of Dr. Testa, and compares the action of picrotoxin with that of cinchonidin. He says:

1. Cinchonidin produces a less complete convulsion, since the motor muscles of the eye, the tongue, and the bladder are rarely affected, while these are always involved with picrotoxin.
2. The convulsion caused by cinchonidin is at first clonic, afterward tonic; while with picrotoxin it is at first tonic, afterward tonic and clonic.
3. By cinchonidin those muscles which are most used in the normal life of the animal are most affected; while by picrotoxin the muscles of the back and neck suffer most.
4. Cinchonidin does not cause convulsions in rabbits, even in a poisonous dose, while these animals are very susceptible to the action of picrotoxin.
5. Cinchonidin has no convulsive action in hibernating animals (frogs, lizards, and toads), while picrotoxin causes violent convulsions.

From these and many other facts the authors came to the conclusion that picrotoxin has not the same seat of action as cinchonidin, and that it provokes convulsions by other mechanism. Picrotoxin acts on the medulla oblongata, since it determines epileptic attacks in decapitated frogs and pigeons whose brains have been removed, and these attacks are even more intense. These are the conclusions at which they have arrived:

1. Picrotoxin may determine true epileptic attacks. These attacks may be very complete, preceded by cry. They commence ordinarily with tremors of the head or contractions of the muscles of the face, and are progressively diffused through the whole organism. There is loss of consciousness; the animal falls; there are abundant salivation, tonic and clonic convulsions, loss of urine, convulsive rolling of the eyeballs, convulsion of the tongue, which is often bitten, arrest of the respiration and heart.
2. Convulsions from picrotoxin are independent of the psycho-motor centres, since they are more intense when these are removed.
3. Picrotoxin displays its action first on the bulb and on the parts connecting the cerebral and spinal centres, then on the spinal centres, by the last action resembling quinine and differing from cinchonidin.
4. Picrotoxin brings into relief a functional antagonism between the psycho motor centres and the motor centres of the medulla oblongata and spinal cord.
5. Picrotoxin can also give rise to convulsions after the medulla oblongata is removed. This conclusion is deduced from the experiments on frogs, and in this case the convulsion is later and is tonic.
6. The convulsions of the limbs due to picrotoxin depend on the action which is displayed on the medulla oblongata, and is propagated by the spinal cord, and, secondly, by the direct action of the spinal centres.
7. In frogs the spinal functions are more developed than the cerebral, and, *vice versa*, in dogs and other higher mammals the cortical motor centres of the brain are more developed than the spinal centres.
8. The convulsions due to cinchonidin are of cerebral origin, and are not obtained when the psycho-motor

centres are removed. The convulsions due to picrotoxin are of spinal or bulbar origin, and are more intense after the removal of the higher centres.—*London Medical Record*, May 15, 1883.

HOT WATER AS A GARGLE.—Dr. Ritzy has found hot water systematically employed as a gargle of great benefit in overcoming the sensation of rawness incident to acute pharyngitis. He found that the use of hot water paled the red and inflamed mucous membrane more or less permanently. And so far as unpleasant personal sensations went, it cured the pharyngitis. He also believes that this simple plan of treatment would prove beneficial in diphtheria, in patients old enough to gargle intelligently. In ordinary tonsillitis hot water, he thinks, would hardly fail to act well. The water should be used as hot as can be well borne, and gargling should be practiced for several minutes at a time.—*The Medical Age*, May 25, 1883.

THE USE OF ANÆSTHETICS DURING LABOR.—Dr. Savill, in the *British Medical Journal*, May 12, 1883, indicates what he believes to be the main precautions, the observation of which would render the use of chloroform perfectly justifiable: 1. There are certain women who have a tendency to flood at every confinement, and others in whom there seems an already too great relaxation of fibre—weak anæmic females in their eighth or tenth confinement; and to these it would be inadvisable to give chloroform, except for necessity. Happily, it is not these women who suffer the most pain, but rather those strong healthy primiparæ whose pelves and general build approximate to the masculine type. 2. We should not give it when labor is complicated with severe vomiting, or with acute heart or lung disease, unless there be imperative call for it. 3. It should not be given to the full extent, except for operation, convulsions, or spasm of the cervix; and then it is most necessary that one person should devote his entire attention to it. 4. The inhalation should be stopped directly we find the pulse becoming very weak, or the respiration irregular. 5. Anything which makes us suspect a fatty or enfeebled cardiac wall should make us cautious in the use of chloroform. Here, as in cases other than those of labor, it is not the most extensive valvular disease (so long as it be attended by compensating hypertrophy), but the atrophied or degenerate wall that constitutes the source of danger. Unfortunately, the signs of these conditions are subtle and uncertain. Fatty heart may be suspected by an exceedingly feeble cardiac impulse, combined with an almost inaudible first sound; or attacks of dyspnea, vertigo, and syncope, in the absence of anemia, or valvular lesion; or the copious deposit of fat in other parts of the body, and the occurrence of dropsy without adequate cause. A dilated heart may be suspected by increased area of præcordial dulness, combined with epigastric and venous pulsation, and a want of correspondence between the violence of the cardiac impulse and the strength of the pulse. Pericardial adhesions also form a great source of danger. They may be suspected when the heart's apex is fixed above its normal position, and does not shift with respiration; or when there is depression instead of protrusion of intercostal spaces over the position of the apex, giving a wavy character to the cardiac impulse. 6. In all cases, we should take extra care to prevent the occurrence of hemorrhage after birth; by giving a full dose of ergot when the head reaches the perineum; by ceasing the chloroform immediately it is born; and by rousing the patient from her lethargy as soon as possible.

PRIMARY ACUTE MILIARY CARCINOSIS.—A sufficiently searching scepticism is always necessary in medical science, and it is at no time more needed than when an attempt is made to add a new name to medical nomenclature. There are no *à priori* reasons why carcinomatous nodules should not crop up in various parts of the body

under the influence of mere general conditions. It is conceivable that certain of the tissues in certain individuals may as naturally become carcinomatous as those of others fibroid, external agencies apparently having but little influence in the matter. Modern pathology, however, gives an important place to the doctrine of infection, and in the presence of the actual the mind instinctively turns from the merely conceivable. There can be no doubt that the majority of physicians would be extremely careful to exhaust every source of infection before coming to the conclusion, in any particular case of cancerous affection of the serous cavities, that they had to deal with a primary carcinosis of those structures. MM. Raymond and Brodeur diligently but unsuccessfully searched for the primary disease in the case which they have reported. The observation was made on a man aged seventy-six, who showed during life symptoms similar to those induced by pulmonary tuberculosis; palpation of the swollen abdomen, moreover, is said to have revealed the existence of disseminated hard nodules, varying in size from a pea to a bean, apparently separated from the observer's hands only by the thickness of the abdominal wall; there were, in addition, periodic febrile attacks simulating ague. To inspection with the naked eye, tubercles and nodules of carcinoma are sometimes wonderfully similar. The microscopical characters described in the above case were those of genuine carcinoma, growths from the pericardium, pleura, and peritoneum having essentially the same structure. There was a tumor in the liver which the authors assured themselves was nothing more than a cavernous angioma. Charcot has recorded two similar cases also occurring in old age, and, like the present one, having no hereditary taint. If the observations be true, we must recognize the existence of the disease which is called "primary acute miliary carcinosis."—*London Lancet*, March 31, 1883.

FREE INCISION IN PURULENT PERICARDITIS.—At the last meeting of the Royal Medical and Chirurgical Society (*Lancet*, April 28, 1883), Dr. West read a report of the above case, which terminated in the recovery of the patient. A boy, aged sixteen, came under treatment with a large pericardial effusion. The symptoms became so urgent that paracentesis was performed. Pus was obtained. Three days later paracentesis was again performed, and subsequently the pericardium was laid freely open, evacuated, washed out, and a drainage-tube inserted. The temperature never rose, and the boy recovered completely in five weeks, the only feature of interest being an attack of general urticaria, which came on about a week after the operation and lasted three or four days. In support of the diagnosis, a case was referred to in which what was supposed to be a mediastinal cyst was frequently punctured, but it proved to be, on post-mortem examination, a case of chronic pericardial effusion. The points of clinical interest discussed were: 1, the absence of any special signs to indicate the nature of the effusion; 2, the operation and the place selected for puncture; 3, the amount of the fluid evacuated; 4, a peculiar epigastric prominence, noticed before paracentesis, which disappeared after operation; 5, the attack of urticaria; 6, the pulsus paradoxus. A short account was then given of the only other recorded case of incision of the pericardium for purulent pericarditis, by Prof. Rosenstein, of Leyden, which also recovered. Dr. West also read a paper on the statistics of paracentesis pericardii. A complete list of the recorded cases up to date was given in a tabular form, with the addition of several cases hitherto unpublished. The history of the operation was briefly referred to. The cases were discussed under the headings of sex, age, causes (rheumatic fever, scorbutus, phthisis and pleurisy, miscellaneous, purulent pericarditis), length of illness before operation, the effect of the operation, the nature of the fluid; the quantity of the fluid, the number of punctures, the modes of operation, the place of puncture. The following con-

clusions were drawn: 1. Paracentesis pericardii is not only justifiable, but an operation which may be safely undertaken with ordinary precautions, for only one case is recorded in which the operation was in itself fatal, and with this exception all the patients were greatly relieved by the removal even of small amounts of fluid, and many recovered completely who would probably have died had the operation not been performed. 2. The most suitable place for puncture is, in ordinary cases, in the fifth left intercostal space, one inch from the edge of the sternum; but if the pleura be adherent, the puncture may be made safely much further out, and even in the sixth space. 3. The instrument employed should be a trocar and canula, with or without aspiration. 4. The operation may be performed with advantage, not only in the pericardial effusions of rheumatic or primary origin, but also in those which occur in the later stages of general dropsy, if it should appear that the fluid in the pericardium is adding to the difficulties under which the heart is placed. 5. Purulent pericarditis is best treated on general principles, like empyema. 6. The pericardial sac may be safely opened and drained. 7. This treatment, moreover, appears to be the only one which offers the slightest hope of recovery. 8. The results do not seem to be as unfavorable as those of empyema, for the walls of the cavity are better able to contract rapidly, and thus permit of the obliteration of the cavity.

SALICYLATE OF ZINC.—This salt is very soluble in water, and dissolves also in alcohol and ether. The medical properties attributed to salicylate of zinc are that it forms a valuable antiseptic and astringent agent. In certain kinds of cancerous ulcers it has, we are told, given some excellent results, and has been used successfully in gonorrhœa, as an injection, in solution containing one-half to one per cent. of the salt. Messrs. Poignet and Demarres, two French pharmacists, assert that it is preferable to sulphate of zinc as an astringent in ophthalmic affections, and in other cases, since it combines with its astringent action the antiseptic properties of salicylic acid.—*The Monthly Magazine of Pharmacy.*

COMBINED EXTERNAL AND INTERNAL ŒSOPHAGOTOMY.—Among the conditions recently advanced as indications for gastrotomy are the so-called impermeable cicatricial strictures of the lower portion of the œsophagus. They have been placed in this category because of the generally entertained belief that their removal by operative measures was either impossible or attended with the greatest danger to life. While unwilling to deny that gastrotomy may be called for in certain cases, Professor Gussenbauer believes that many, if not all, œsophageal strictures of cicatricial origin, even in the thoracic portion of the tube, or at the cardia itself, may be relieved by an operation of much less gravity. He relates two cases in the *Zeitschrift für Heilkunde* of March 20, 1883, in which he performed the double operation of external and internal œsophagotomy with success. The first case was that of a young woman who had taken about an ounce of sulphuric acid with suicidal intent. The attempt against her life was unsuccessful, but it resulted in the production of a double stricture of the œsophagus, one in the cervical and the other in the thoracic portion. It was determined to perform external œsophagotomy, and accordingly an incision was made in the neck below the level of the cricoid cartilage, when the upper stricture was readily cut by a probe-pointed bistoury passed on a director. The lower stricture was very tight, but after several attempts a filiform bougie was passed. Using this as a guide, the operator introduced a fine director and then incised the stricture in several directions with a hemiotome. The patient made a rapid recovery and was able to take solid food with ease. Owing, however, to neglect on her part in passing the bougies, a recontraction took place. The same operation was

performed a second time with equally successful result. The second case was that of a child, to whom a teaspoonful of a fifty per cent. solution of carbolic acid had been given by mistake. The stricture was situated at the cardia, or immediately above it, and was so close as to prevent the passage of the smallest sized bougie introduced through the mouth. The child could take no nourishment, even water being regurgitated. The œsophagus was opened as low down as possible, and the attempt was then made to pass a sound. But it was only after repeated trials that the operator succeeded in introducing the finest filiform. The subsequent steps were the same as in the preceding case, and the results of the operation were equally favorable. Reasoning from his success in these cases, Dr. Gussenbauer thinks that the attempt to relieve cicatricial strictures of the lower portion of the œsophagus by the combined method should always be made before resorting to the much more serious operation of gastrotomy.

INOSCUATION BETWEEN THE LYMPHATICS AND THE CAPILLARY BLOOD-VESSELS.—The question of the lymphatic circulation is one which is as yet by no means settled. Mascagni and Sappey hold the opinion that there is an anastomosis between the ultimate arterial ramifications and those of the lymphatic system, but most microscopists deny that such a connection exists. In a recent communication, addressed to the Académie des Sciences of Paris, Dr. Alphonse Guérin has embodied the results of some experiments undertaken by him to determine this point. He selected as the field of his study the pulmonary pleura, a membrane admirably adapted for such purpose, by reason of the number and superficial location of its lymphatics. He found that if an injection of water were thrown into the pulmonary artery, in a few seconds the fluid would enter the lymphatic vessels, distending them so that they were readily visible beneath the pleura. Were it not conceded that there is no venous plexus upon the surface of the lung, one would be tempted to regard the injected vessels as venous radicles. But aside from that, Dr. Guérin determined the nature of the vessels by tracing the injection into the lymphatic glands lying near the bronchi. Before drawing any practical conclusions from these experiments, the speaker endeavored to answer any objections that might be raised against his interpretation of the facts observed. To the first objection, that it was not possible to conceive of a direct communication between the two systems which would not permit the passage of red blood-globules from one to the other, he stated that he had never observed this to occur; further, it had been shown by Sappey that the red corpuscles could not pass through a vessel less than 2 mm. ($\frac{1}{25}$ inch) in diameter. The fluid passing first after the injection of the pulmonary artery was of a red tinge; but this only proved that a fluid analogous to the blood-serum, containing hemoglobin in solution, could pass through the anastomosing vessels. It might also be urged that post-mortem epithelial changes may permit of a communication between the two sets of vessels, which did not exist during life. But this objection was disposed of by some injections practised upon rabbits at a time when no post-mortem destruction could possibly have commenced. Dr. Guérin thought he had found in this anastomosis an explanation of some of the phenomena of inflammation. If the serum of the blood can pass from the arterial capillaries to the lymphatics, the white corpuscles can do the same. In accordance with these views, he regarded suppuration as arising from the passage of the white corpuscles of the blood into the lymphatic vessels rather than from their extrusion through the capillary walls. The first phenomenon, therefore, of suppuration was the invasion of the lymphatic territory by the white blood-globules, this invasion taking place through the anastomotic connections of the two systems.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 16, 1883.

THE CONVALLARIA MAIALIS—ITS ACTIONS AND USES.

It is a matter of gratification that this beautiful little flower, whose clusters of white hanging bells greet us at this season of the year in many a garden, on the heath, and even by the solitary wayside, is of real therapeutic value, worthy of a rank beside the purple foxglove.

The convallaria is one of our newest remedies, scarcely known to the profession three years (in fact, Dr. Ralph D. Ary's first report bears date October, 1881), yet it has already won for itself an established place in the treatment of adynamic heart affections.

Dr. D. Ary learned the use of this plant while on a tour through his native country, Russia, where it is used as a favorite diuretic and tonic of the heart in chronic dropsical effusions.

Drs. Bogoyavlenski and Troitsky, of St. Petersburg, had previously experimented with the convallaria and called the attention of the profession of Russia to its merits. Their articles were, by Dr. Ary on his return to this country, translated and published, chiefly in the *Therapeutic Gazette*.

Early in the year that has passed, Professor Germain Sée, of the Hôtel Dieu, Paris, learning through Professor Botkin, of St. Petersburg, of the usage of the lily-of-the-valley, in Russian practice, introduced it into his hospital service, besides submitting it to physiological experimentation in his laboratory. The results of these experiments with the convallaria were published in the *Bulletin Gen. de Therapeutique*, July 30th, and were communicated to the medical profession of the United States, through the columns of THE MEDICAL RECORD, in an article by Dr. Hurd, of Newburyport, bearing date September 9, 1882.

Since THE RECORD of the above date called attention to this new remedy, it has been very extensively prescribed throughout this Union, and it is safe to say that there is not a city or hamlet in the land where it has not been tried in cases of cardiac dropsy. In fact, it is now one of the remedies that are first thought of in such cases.

Physiological actions.—Experiments on animals show that convallaria has a marked tonic action on cardiac innervation; small doses strengthening, while slowing the heart's pulsations, large doses speedily tetanizing that

organ. In fact, death occurs, in poisoning by this drug, from tetanus of the heart, and the heart's cavities are found empty. Experiments on the human subject show that there is a marked effect on the heart and circulation, but as yet no cases of poisoning have been observed. It is probable that the toxic dose in the human subject would be large.

In pathological conditions of cardiac adynamia, characterized even by extreme asystolism, the effects of the convallaria are often most beneficial, but it must be taken for granted that the heart muscle is in a state to respond to excitation; if fatty degeneration be much advanced, it is useless to expect any considerable effect from any remedy. The convallaria will generally do what any medicament can do—cases that have failed to derive benefit from digitalis are often helped by it. In functional palpitations, from whatever cause, we have known speedy relief to be derived from ten-drop doses of the fluid extract of convallaria flowers. In the asystolism of Corrigan's disease the heart's action has been strengthened, dropsical effusions in the thorax and subcutaneous cellular tissue have been removed, and the patient made every way more comfortable. But it is especially in the dropsy from mitral insufficiency, where the heart's pulsations are weak, rapid, and irregular, that the most marked benefit has been derived. We have reports of several cases awaiting publication—where the parietic heart has been aroused to new life and activity, where the sluggish kidneys have gone to work in earnest to remove dropsical accumulations (it is not known whether convallaria produces its diuretic effect in part by a special action on the secretory function of the kidneys) and where in a few weeks the patient has been restored to a fair state of general health, with entire freedom from dropsical effusions, and all under the influence of drachm doses every four hours of the fluid extract of the lily-of-the-valley.

Preparations and doses.—Now is the time, while the plant is in bloom, to save a quantity for use during the coming year. The infusion of the entire plant is a good form in which to give the remedy. Two drachms of the leaves may be steeped in a pint of water and the whole taken during the twenty-four hours. The alkaloid of convallaria has been little given, and we have no certain data with regard to its administration. The alcoholic tincture, made by macerating four ounces of the flowers in a pint of alcohol, is a very reliable preparation, and may be given in doses of from ten to forty drops every four hours. The liquid extract of the root is a good preparation, but must be given in larger doses than any alcoholic preparations of the leaves and flowers. Whatever form of the medicament may be chosen the dose may be gradually increased without fear of evil results; unlike digitalis it has no cumulative action to be dreaded. Sometimes it is well to interrupt the action of the medicine, and give digitalis for a time. It is almost always indicated when digitalis fails to act.

We have endeavored not to be unduly eulogistic of this new cardiac tonic. Perhaps the sober second judgment of the profession will give it a lower place in therapeutics than has been here assigned. It must, however, always from henceforth rank as a heart corroborant of great utility.

MEDICAL INCOMES IN NEW YORK.

A DAILY paper of this city has recently published the results of a reporter's investigations regarding the income of some of New York's prominent physicians and surgeons. The publication is an impertinent one, yet we cannot but notice the very moderate amounts at which the incomes of even the best-known practitioners are fixed. The largest do not exceed \$25,000, and the average in a list of about thirty names is about \$15,000. We are inclined to think that the estimates are somewhat under the real amount in many cases. Yet there is no doubt that the enormous sums of \$60,000, \$80,000, and \$100,000 per year, which it is rumored some New York medical men receive, are great exaggerations. We doubt if the average income of the New York City physician exceeds \$5,000, and there is a very large number, if not a majority, who do not get even this sum. A doctor has to work hard to make \$400 a month, unless he has the better class of patients.

With the increase in scientific knowledge and practical skill, there has been an increase, in late years, in the average incomes of professional men, but the maximum of individual incomes has not been raised. No physician or surgeon of the present day has probably ever reached the £21,000 a year which Sir Astley Cooper and Sir Everard Home are reputed to have earned, nor the £1,000 single fee which the former once received. Forty years later, according to Timbs, there were not six medical men in London who received over £5,000 a year, and recently a London writer estimates that the number is not above thirty.

Neither in New York nor in any other American city is it possible for a physician, without some special genius, to make a fortune. The more he earns the more he is obliged to spend, so it happens that a leading specialist, who had an income of \$10,000 to \$15,000 yearly, died recently insolvent, and the widow of a prominent and widely known surgeon has now to depend upon charity.

This is the darker side. Many members of the profession, perhaps the majority, earn enough to live comfortably, educate their families, and supply themselves with some luxuries; and their practice, though hard enough, does not involve so much physical wear and tear as that of their provincial and country brethren.

THE NEW YORK ACADEMY OF MEDICINE AND THE STATE SOCIETY.

*"The kettle to the pot denies
Its sordid superficies."*

SOME attempts have been made to excuse the action of the Academy of Medicine at its last meeting, by comparing it with the action of the State Society in adopting the State Code. "It [the Academy's action] was done," says Dr. Squibb, "exactly as the New Code was adopted in the New York State Medical Society," in 1882. Such a statement illustrates, in an interesting manner, how partisan zeal will warp the most truth-loving mind.

The differences between the action of the Academy and of the State Society are several. For a year every county society knew, or should and could have known, that the Code of Ethics was to be changed; notice of the exact change could not be given, because it would

have been forestalling a committee's report; there was no previous pledge that the matter of ethics should not be introduced; there was no secret and organized attempt to surprise the Society; and there were no threats of "throttling it" at the time.

We have never heard that the pot was thought the more of because it called the kettle black, and the managers of the Academy fiasco will not regain respect by crying that others are just as bad as they.

AUTOPSIES IN THE ARMY.

NOT long ago we mentioned the fact that the Surgeon-General of the Army had issued a circular directing members of the medical corps to make autopsies whenever practicable. It appears now that the carrying out of this order will meet with some opposition.

A few weeks ago a soldier was accidentally killed on the target range. The bullet struck him in the upper lip and passed directly through his brain. He died in less than two minutes. A post-mortem was held the next day, all the viscera being carefully examined. A correspondent of the *Times*, using this incident as a text, protests against the right and legality of the Surgeon-General to order or permit such examinations. He says:

"This enlisted man did not sell nor convey his body to the medical corps; there is nothing either expressed or implied in the contract entered into between the United States and this enlisted man which gives his body to the post surgeon for dissection after death. When dead, killed in the line of duty, his body is entitled to and merits decent treatment and honorable burial. His body does not receive decent treatment if it be subjected to the surgeon's knife without his consent previously obtained."

We understand that the body of a dead soldier should receive the same respect and consideration as that of any other citizen—and no more. No one in private life makes a bargain with his doctor not to hold an autopsy. It would be foolish and impracticable to attempt getting an expression of opinion from each recruited soldier as to his exact post-mortem disposition, since in many cases autopsies are absolutely demanded; nor is autopsical examination "indecent treatment."

The rule which holds in civil life has been found satisfactory, and it can be applied in a measure to the soldier. Autopsies should be allowed, provided responsible friends or relatives do not object. The Surgeon-General has no moral right to order an autopsy in opposition to the wishes of these. Yet it must be admitted that the complications and unusual conditions of military life make any special regulation impossible.

THE IRON CURTAIN AT WALLACK'S AS A SAFEGUARD FROM FIRE.

WALLACK'S Theatre is one of the two or three theatres in the city which have been pronounced perfectly safe as regards fire. This security is attributed to the large number of exits and to the fact that there is an iron curtain separating the auditorium from the stage, which can be let down in case of fire. This curtain was put in at a time when iron curtains were thought to be the great and indispensable feature of a fire-proof theatre.

Further experience seems to throw some doubt over the value of this opinion. At the International Hygienic Exhibition, now open at Berlin, the display of iron curtains among the life-saving apparatus is small, and there is a well-developed opposition to their use. A very powerful argument has recently been furnished to this side. The National Theatre of Berlin burned down not long ago. There was no one in it at the time, and no lives were lost. The iron curtain was down, however, and we are informed that before the house could possibly have been emptied this curtain came crashing over into the parquet.

It would be well if the public could be assured that such an accident can not happen at Wallack's or other theatres where this partition has been, or is likely to be, introduced.

News of the Week.

DEATH OF DR. NOAH C. LEVINGS.—Dr. Noah C. Levings died at his residence in this city June 11th, at the age of fifty-nine years.

THE OREGON STATE MEDICAL SOCIETY met during the past week at Portland.

THE PENNSYLVANIA ANATOMY BILL.—The Legislature of Pennsylvania has passed the new bill providing for a supply of anatomical material substantially as it was drafted.

ANOTHER OFFICE THIEF.—An office thief, who is known under the name of "Dutch Lena," is around again. She is about thirty-five years of age, of sickly aspect, and claims to be sent by some neighboring druggist to consult the doctor on account of uterine ailment. She says that several operations have been performed on her by prominent specialists. She finds out when the doctor is absent from home, when she calls, and, under pretence of writing a note, steals whatever she can.

THE DEATH OF DR. WILLIAM E. KENNEDY, an old and widely-known physician of New Orleans, is announced.

WHAT OTHER PEOPLE THINK OF THE AMERICAN MEDICAL ASSOCIATION.—Seldom have so many bitter and contemptuous comments upon the medical profession been called out as by the recent action of the American Medical Association. We print the following specimen from the *New York Times*:

"The labors of the American Medical Association were crowned at its final session by the expulsion of Dr. Goodwillie, of this city, upon the express ground that he adhered to the Code of Ethics of the New York State Society. In other words, a physician whose standing is not challenged in any other respect is declared unworthy of professional association because he reserves the right to attend a patient in consultation with an 'irregular' physician of the patient's own choosing, whenever, in his judgment, any emergency requires him to do so. And this reservation is regarded as the violation of a code of 'ethics.' The doctors who take this view would appear to be cruel bigots if they did not present so much more prominently the aspect of simple geese. This is not the

spirit of a learned profession; it is the spirit of an ignorant trades-union, bent upon punishing 'rats.' The men who made it and who adhere to it must believe not so much that it is the business of physicians to heal the sick as that it is the business of the sick to furnish constant and remunerative employment to a carefully limited number of 'regular' physicians."

The above is somewhat strong. No one, of course, questions the legality or logical necessity of the Association's action—which was hardly a formal expulsion. But to refuse to consider that there is anything wrong in a set of by-laws which excludes several thousands of reputable and hundreds of eminent physicians, this naturally excites criticism.

Reports of Societies.

MEDICAL SOCIETY OF NEW JERSEY.

One Hundred and Seventeenth Annual Convention, held at Atlantic City, June 12 and 13, 1883.

(Special Report for THE MEDICAL RECORD.)

TUESDAY, JUNE 12TH—FIRST DAY.

THE Convention was called to order by DR. JOHN W. SNOWDEN, of Waterford, President, after prayer by the REV. JOSEPH GARRISON, D.D., of Camden.

An "Address of Welcome" was tendered by DR. BOARDMAN REED on behalf of the Atlantic District Medical Society. He was followed by the HON. CHARLES MAXWELL, Mayor of Atlantic City, who in a very happy manner greeted and made welcome the medical fraternity of New Jersey.

After the reading and adoption of the minutes of the last annual meeting, the recent action of the American Medical Association

IN REGARD TO THE CODE OF ETHICS,

as supported by that body, was brought to the attention of the meeting. A lively discussion ensued, in which much was said both in favor of and against the position maintained by them. As there was some misunderstanding with reference to the precise nature of the Code of Ethics in question, Dr. Atkinson, Secretary of the American Medical Association, was asked to explain. He stated that the Code of this year, which all delegates were required to sign, did not differ in any particular from the original Code as formed by the American Medical Society. It was then urged by Dr. Price that a Society which frames a law or laws had the right to enforce compliance with such law or laws, so far as delegates were concerned who wished to be connected in any manner to it. Dr. H. H. Tichenor stated that the State Society should assert its loyalty to the "old Code" without modification.

DR. EZRA M. HUNT then presented the following resolution:

Whereas, The American Medical Association has at its late meeting made new requisition of delegates before their names were allowed to be enrolled;

Resolved, That in nominating delegates to that body the Nominating Committee be requested to confer with our Committee on Ethics, and if they think necessary, with the Society, as to the propriety of this course, and what action needs to be taken in reference thereto.

During the discussion that followed, a motion was made to "lay the resolution on the table," and after a very close contest the motion was carried.

Dr. Hunt stated that a code of ethics should not be presented for unconditional acceptance, which, because of some questionable modifications, rendered them liable

to debate, if inspection by a special committee were allowed. Also that a body maintaining such a standard of ethics should in all fairness listen to suggestions when so much of importance is involved.

After the announcement of committees by the President the meeting adjourned to 7.30 P.M.

FIRST DAY—EVENING SESSION.

The meeting was called to order by DR. STEPHEN WICKES, of Orange, First Vice-President, after which the President delivered his address.

PRESIDENT'S ADDRESS.

"The Advances Made in Medicine by Physical Diagnosis." He stated that in the early history of medicine physical diagnosis was unknown. The first means of this sort was introduced by Hippocrates, and styled succussion. The means of diagnosis of diseases of the chest were then considered, the various appliances which are used as aids being well enumerated and described. Among the more recent additions since the time of Laennec are the sound of pleuritic friction by Raynaud in 1829, pericardial friction by Collin in 1831, and the proper interpretation of sounds heard over the vessels. Phonometry, as described by Prass, is a new method of investigating the condition of the thoracic and abdominal organs. It consists in placing a vibrating tuning-fork on the surface of the chest or abdomen and determining by the intensity or feebleness of the tone it gives whether the subjacent organs do or do not vibrate simultaneously, that is whether they are permeable or not to air. The paper was an exhaustive treatise on the subject of physical diagnosis and contained much valuable information. At its conclusion the address was appropriately accepted and referred for publication in the "Transactions" of the State Society.

DR. H. H. JAMES, Chairman of Committee on

WHERE AND OF WHOM RELIABLE VACCINE VIRUS MAY BE OBTAINED,

then made a report, in which he stated that each physician for himself ought to investigate whether the virus he uses is pure and reliable. Owing to the prevalence of small-pox for the last few years, the demand for vaccine lymph has been great; so that in order to meet this need a quantity of unreliable virus has been thrust on to the professional community by the "vaccine farms," "vaccine companies," etc. Dr. Wm. M. Nelsh, Surgeon of Municipal Hospital, Philadelphia, says that one propagator is able to charge from eight thousand to fifteen thousand points from one heifer. This is four or five times the number collected by more reliable producers. There is a so-called patent lymph advertised and sold throughout the country. One of these specimens was examined by Dr. J. Mitchell Prudden, of New York, and he found it to contain epithelial cell, hairs, some broken off, others having their roots attached. Beside these things there were fragments of vegetable substances of various kinds. It is thus shown how impure and unreliable much of the lymph is. The author of the paper said that perfectly reliable virus might be obtained from Dr. Henry A. Martin & Son, Boston, or from Dr. Frank P. Foster, of New York. He closed his report by saying that the propagation of animal virus is a service requiring very exact management, and should be committed to no hands but intelligent and conscientious physicians.

After the reading of the paper it was discussed by DR. J. D. OSBORNE, of Newark, who said that physicians are much to blame for the unpleasant results which so often follow vaccination with animal virus. He considered the humanized lymph much more reliable.

DR. PRICE, of Camden, agreed with Dr. Osborne, and further stated that after vaccinating a child with human-

ized virus he had placed it in the bed with its father, who had small-pox, without any fear of the disease being transmitted from the sick to the healthy. No unfavorable result followed.

DR. WRIGHTSON, of Newark, then stated that in Maryland there was a State law regulating the use of vaccine lymph, physicians being provided with reliable virus *gratis*. He made a motion to the effect that such a law be made in New Jersey, but it was not carried.

WEDNESDAY, JUNE 13TH—SECOND DAY.

The meeting was called to order by the President after which the Nominating Committee reported as follows:

President—Stephen Wickes, of Orange; *First Vice-President*—P. C. Barker; *Second Vice-President*—Joseph Parrish; *Third Vice-President*—Charles J. Kipp; *Recording Secretary*—William Pierson; *Corresponding Secretary*—Wm. Elmer, Jr.; *Treasurer*—W. W. S. Phillips.

Standing Committee—T. J. Smith, Chairman; E. J. Marsh; S. S. Clark.

Delegates to American Medical Association—George Bayles, H. G. Cook, J. Condict, W. R. Little, E. J. Marsh, D. A. Currie, E. L. B. Godfrey, A. Coles, B. A. Watson, George F. Welch, L. A. D. Allen, D. B. Ingersoll, H. W. Elmer, Frank Ashhurst, J. D. Heritage.

Delegates to State Medical Societies.—Pennsylvania—Theo. A. Varick, T. L. Laws, D. Berryman; *Connecticut*—D. C. English, —Sonnors, St. John; *Rhode Island*—Rich Page, Boardman Reed, L. J. Gordon; *Massachusetts*—E. North, E. M. Hunt, J. L. Bodine; *Vermont*—George H. Larison; *Maine*—Joseph North, Jr., W. K. Newton, A. C. Hunt.

Drs. T. A. Emmett and Isaac E. Taylor were elected honorary members.

The subject of the "Fellow's Prize Essay" for 1884, will be "The Etiology and Pathology of Septicæmia and Pyæmia."

DR. JOSEPH PARRISH, of Burlington, read a very interesting paper on

SOME PROBLEMS IN INSANITY,

in which he stated that places of retreat should be provided where the patients should in every instance have the most careful attention, and where there should not be unnecessary restrictions enforced. He likewise asserted that many of the so-called lunatics in the New Jersey State Asylums are not insane, and that if only the *insane* were confined in the asylum, there would be much more vacant room than can at present be found.

The doctor, after the paper was duly accepted and discussed at some length, offered the following:

Resolved, That it is the

OPINION OF THIS SOCIETY THAT A LUNACY COMMISSION SHOULD BE APPOINTED

by the State authorities and as a means of protecting the pauper insane especially, and of improving the general condition of the almshouses of the State.

This resolution was not adopted as first presented, but was remarked upon and finally adopted as amended by Dr. E. M. Hunt, in the following form:

Whereas, The condition of the insane poor in the several county houses of the State is such as to warrant investigation by this Society, it is therefore

Resolved, That the Chair appoint a committee whose duty it shall be to inquire into the management of the asylums and poor-houses in the several counties, as often as may be suitable, and in a friendly and unofficial manner acquaint themselves with the condition of the insane, and report to this Society at its next annual meeting.

DR. GEO. BAYLES, of Orange, then read a very instructive paper on

CAUSES OF MELANCHOLIA.

In this paper he showed, by deductive reasoning, what may be regarded as the initial agencies at work in the world to provoke a tendency to mental incompetency through cerebral innutrition. Melancholia is considered as a term of very general significance, applied very generically to many, if not all, conditions of mental alienation preliminary and leading to insanity. The etiology of melancholia includes two sets of causes, "the remote predisposing" and the "immediate exciting." It was the former that the essayist paid special attention to. The great cosmic causes, and those of heredity, have heretofore been considered as mainly those upon which the melancholic dyscrasia depends. Dr. Bayles claims that in many periods of the world's history, and in many communities, these special causes are not directly operative. There is another cause, found within the system of the mother, derived from the impressions made upon the generative zone through the emotions. The influence of the emotions upon the nutrition of the ova, upon the nutrition of the fetus in utero, and the post-natal life, is fully set forth. The writer claims that a sufficient first cause of depreciated mental and nerve force is all that is necessary for the successful operation of the later or secondary causes. The doctor claims the unqualified importance of the pre-natal excellence of the germ of future life. After pointing out what should be the true physico-mental states accompanying conception, it is shown how this bears upon nutrition or innutrition in relation to the etiology of melancholia. A brain inheriting normal and healthy conditions is never susceptible to motives of melancholia, excepting under the direct influences of acute organic disease. This paper seems to be an extension of the writer's views as presented in a paper read before the New York Medical Journal Association, about four years ago, entitled "The Malady of Innutrition."

The committee appointed at the last annual meeting of the New Jersey State Medical Society to present a plan for putting into effect the suggestions made by the President

IN REGARD TO THE CURRICULUM OF MEDICAL STUDY, reported as follows: They suggest that when possible a regular college education be had, and that when such a course is impossible an equivalent or near approximation to it be exacted, and that the applicant should produce a certificate of a completed course in a reputable academy or high school, in which are taught in addition to the English classical and mathematical branches required for admission to our more advanced colleges, intellectual and moral philosophy, rhetoric, logic, and the elements of physics, chemistry, and natural history, including botany and zoölogy.

In default of either a college diploma or academic certificate as above defined, the applicant, before being taken under the care of a physician for medical instruction, should be subjected to examination and approved by a competent censorship appointed under the authority of the State Medical Society. In order that the desired result might be attained it was recommended that the action of this Society be communicated to the medical societies of the several United States, to the National Medical Association, as well as to the local medical organizations, with the request that they co-operate with the New Jersey Medical Society.

DR. C. J. KIPP, of Newark, then read a very practical and interesting paper on

THE MANAGEMENT OF CASES OF IRITIS.

He stated that in the treatment of all cases of iritis, no matter what the origin, the first indication is to secure dilatation of the pupil, and for this purpose the most reliable mydriatic is the sulphate of atropine. In recent

cases five or six instillations of a few drops of a one per cent. solution of atropine, made at intervals of five minutes, will usually break up any adhesions which may already have formed, and cause complete dilatation in the course of a few hours. When, as is sometimes the case, the atropine does not have such an effect, six or eight leeches should be applied to the temple. When leeches cannot be used with benefit, a brisk cathartic will sometimes have a very desirable effect. In all severe cases the patient should be put to bed, or at least kept in a dark room till the severity of the disease is broken. Dilatation of the pupil should be maintained until *all irritation* has subsided. If such remedies as have been recommended do not produce a larger pupil, mercurials should be given by inunction or by the mouth. In some cases muriate of pilocarpine will answer very well. In his recent practice the doctor has been able to dispense with mercurials in cases where there were not marked symptoms of secondary syphilis. To relieve the pain morphia is to be given in large enough quantities to produce sleep at night. Paracentesis of the anterior chamber will give relief if the pain is due to increased tension of the globe, a symptom not at all uncommon in the so-called serous iritis. If after the iritis the pupil is excluded, an iridectomy should be made as soon as practicable. It would be profitable to report in full this paper which deals with such an important lesion, but space and time forbid.

DRS. MARSH and BAIKWIN were appointed a committee to arrange for the entertainment of the Society at the next annual meeting at Cape May, N. J.

MASSACHUSETTS MEDICAL SOCIETY.

One Hundred and Second Annual Meeting, held in Boston, Mass., June 12 and 13, 1883.

(By Telegram to THE MEDICAL RECORD.)

TUESDAY, JUNE 12TH—FIRST DAY.

THE one hundred and second annual meeting of the Massachusetts Medical Society was held at Huntington Hall, Massachusetts Institute of Technology, Boston, Mass., commencing June 12, 1883, Vice-President DR. JOHN H. MACKIE, of New Bedford, presiding.

CONCERNING THE TUBERCLE BACILLUS.

DR. H. C. ERNEST, of Jamaica Plain, read a paper on the "Tubercle Bacillus," giving a *résumé* of the views of Koch, Pasteur, and others, concerning the same, and presenting a large number of original experiments of inoculation with tuberculous matter. In guinea-pigs, operated upon there was always found a causal relation of the inoculation with the death of the animals from phthisis. Several cases of phthisis were also reported, in all of which the bacilli were found in large quantities in the sputa. The same result was obtained in the examinations of cheesy glands, lung cavities, in specimens of milary tuberculosis, and in one case of tubercular iritis. No culture experiments were attempted. The writer coincided with Koch's view to the effect that there was a bacillus which by inoculation was capable of producing tubercular processes, and also that the examination of the sputum of cases of suspected phthisis was of great diagnostic value.

In the discussion which followed, confirmatory statements were made by Drs. R. H. Fitz and W. T. Whitney.

DR. H. R. BOWDITCH believed that the bacillus doctrine gave great weight to the possibility of the contagiousness of tubercular disease, and alluded in passing to the possible benefits of antiseptic respirators. He also referred to the necessity of examining the sputum in doubtful cases of pulmonary phthisis.

DR. ERNEST remarked that no suitable antiseptic had been found for the bacilli. Carbolic acid and other antiseptics acted only very slightly on bacilli. Perhaps re-

peated cultivations, like those of Pasteur in connection with hen-cholera, might prove of service in establishing a means for prophylactic inoculation.

DRS. L. S. WOOD, of Springfield, and W. A. DUNN, of Boston, read papers on "The Uses and Abuses of Ergot," after which the morning session concluded.

FIRST DAY—AFTERNOON SESSION.

The meeting was called to order by President ALFRED HOSMER.

The following papers were then presented: Dr. J. W. Warren, of Boston, on "Glycogen;" Dr. O. F. Wadsworth, of Boston, on "Phlyctenular Diseases of the Eye;" Dr. B. H. Hartwell, on "Minor Injuries of Spinal Cord"—reporting nine cases; and Professor T. M. Clark, of the Massachusetts Institute of Technology, on "Plumbing Appliances," illustrated by working models of water-closets, ventilating systems, and samples of faulty and good plumbing. He spoke of the system adopted in the new bill regulating plumbing in Boston.

At the annual meeting of Councillors in the evening there was the usual discussion and vote

ON ADMISSION OF WOMEN TO THE SOCIETY.

Although the majority of the Fellows seemed in favor of the measure in answer to private circulars, the motion to amend the by-laws so as to admit women was lost.

ELECTION OF OFFICERS.

The following named officers were chosen: *President*—Alfred Hosmer; *Vice-President*—Ira Russell; *Treasurer*—Frank W. Draper; *Recording Secretary*—F. W. Goss; *Corresponding Secretary*—C. W. Swan; *Librarian*—D. H. Hayden.

WEDNESDAY, JUNE 13TH—SECOND DAY.

The meeting was called to order by President ALFRED HOSMER, in the Chair.

The Secretary, DR. FRANK W. GOSS, read the record of last year's meeting, and presented his annual report, announcing the addition of twenty-six Fellows and the death of twenty-seven.

The report of the Treasurer, which was accepted by the Councillors at their meeting the previous evening, was read. The total income of the Society was, \$8,595.79; expenditures, \$7,056.37; balance on hand, \$1,539.42.

On motion of DR. H. H. BOWDITCH, a committee of three was appointed to memorialize Congress in regard to the

DISPOSITION AND CARE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE

and to urge upon representatives the importance of providing fire-proof buildings for its preservation, in connection with the Museum, and distinct from the General Congressional library, also of securing a liberal appropriation for completion of the "Index Catalogue," and for the general purposes of the library. The Chair appointed as members of the committee: Drs. H. P. Bowditch, H. P. Wolcott, and O. F. Wadsworth.

The request of the President of the College of Physicians and Surgeons, that diplomas granted by said college should be recognized by the Society, was, after some discussion, laid on the table.

DR. E. N. WHITTIER read a paper on

RECENT CHANGES IN THE METHOD OF MEDICAL INSTRUCTION.

He briefly reviewed the old system of acquiring knowledge of the science of medicine by studying with some physician, remarking that the method was unsatisfactory and that the practice of medical apprenticeship was, properly enough, practically abolished. It was superseded by the co-operative system of instruction, the stu-

dents having advantages by class instruction of different lecturers and professors, which they could not enjoy while studying with one physician. The rapid growth of hospitals required a larger number of undergraduate appointments. The difficulty was not to get enough, but to properly select from those fitted for such positions.

DR. J. S. GREENE, of Dorchester, read a paper on

NEURASTHENIA,

its courses and its home treatment. The disease was not due to work, but to the competition, anxiety, hurry, and excitement of business and society. Education was one thing, but cramming was another. The latter always caused nervous exhaustion. He then spoke in detail of the influences, more or less, resulting in nervous exhaustion, and considered the different methods of treatment, paying high tribute to those who have endowed hospitals for the reception and treatment of those suffering from neurasthenia.

DR. J. W. SPOONER, of Hingham, read a paper on "Artificial Feeding of Infants."

DR. W. B. GOLDSMITH, one of the examiners at the Danvers Insane Asylum, read a paper on "Early Symptoms of General Paralysis of the Insane."

The following named delegates were then introduced to the meeting: T. J. W. Pray and L. J. Young, of New Hampshire; C. E. Webster, of Maine; E. R. Campbell and George Dunsmore, of Vermont; G. T. Swartz and H. J. Miller, of Rhode Island; G. G. Hopkins, P. V. S. Pruin, and E. N. Brush, of New York, and Alice Bennett, of Pennsylvania.

After an intermission of fifteen minutes

THE ANNUAL DISCOURSE

was delivered by DR. AMOS H. JOHNSON, of Salem. He took for his text the motto of the Society "Natura Duce," and suggested that it should be changed to read "Ratione et Natura Ducibus." He referred to the wonderful progress made in the study of astronomy and electricity during the last few years, and then turned to the consideration of the progress in the science of medicine, saying that it was chiefly the result of judgment and critical observation. He also alluded to the danger of allowing patients to follow Nature as a guide, declaring that in many instances her advice proved fatal. The indifference with which the presence of some contagious diseases was regarded was one of the bad moral influences in the community which had to be met. The science of preventive medicine was of recent growth, but it had made tremendous strides. He expressed the hope that the time would come when State boards of health would be relieved from the fear of political influence, and thus attain their greatest usefulness.

At the conclusion of the address a vote of thanks was tendered to Dr. Johnson. The Society then adjourned.

The annual dinner of the Society took place in the Skating Rink on Clarendon Street at one o'clock, Francis H. Brown, M.D., of Boston, presiding. Among the after-dinner speakers were President Hosmer; President Elliot, of Harvard University; Dr. A. H. Johnson; B. A. Gould, Ph.D.; Rev. Edward A. Horton; Dr. W. H. Hings-ton, of Montreal; Rev. E. C. Bolles, Ph.D.; Dr. John B. Hamilton, Surgeon-General U. S. Marine Hospital Service; Professor E. S. Morse, and President Francis A. Walker, of Massachusetts Institute of Technology. Governor Butler was not present. Especially worthy of note were the remarks of President Elliot on the relation of the medical profession to the poorer classes. He scouted the idea, now maliciously advanced, that the medical profession systematically ill-treat the poorer classes, either before or after death. On the contrary, the poorest pauper to-day had better care than a king's daughter could have had two hundred years ago. This resulted largely from the advance in medical education, which should therefore receive all possible support from the people and those who make and execute the laws.

American Medical Association.

*Thirty-fourth Annual Meeting, held at Cleveland, O.,
June 5, 6, 7, and 8, 1883.*

MEETINGS OF SECTIONS.

SECTION OF PRACTICAL MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

TUESDAY, JUNE 5TH—FIRST DAY.

THE Section was called to order at three o'clock P.M. DR. J. H. HOLLISTER, of Illinois, Chairman, and DR. J. G. LEE, of Philadelphia, Secretary.

The only two papers presented were those by Dr. Robt. D. Murray, of the U. S. Marine Hospital Service, on

YELLOW FEVER,

and by Dr. W. M. Beach, of Ohio, on

MILK SICKNESS.

Dr. Murray being unavoidably absent, his paper was read by DR. F. W. MILLER, of Chicago, also of the Marine Hospital Service. The author advocated putting the patient at once to bed and giving a warm-water bath. Mental tranquillity must be obtained by whatever means. He laid emphatic stress on absolute quiet of both body and mind. The symptoms should be treated with the usual remedies, but very cautiously. Diet must be light, and after a few days tonic; to stop vomiting he employed charcoal early and placed a little ice in the patient's mouth.

DR. CAMPBELL, of Augusta, Ga., advised blood-letting in yellow fever patients. The patient should also be thoroughly vomited with hot water.

The discussion which ensued was participated in by Dr. Elliott, of Pennsylvania, who put his patients to bed immediately, but did not approve of bleeding them; Dr. Bell, of New York, who coincided with Dr. Murray's treatment; Dr. Franklin, of Ohio who depleted such patients with calomel instead of the lancet; Dr. J. B. Hamilton, of the Marine Hospital Service, who advised strict quarantine.

Dr. Beach's paper on "Milk Sickness" was discussed by DR. A. B. PALMER, of Ann Arbor, Mich., who thought that the germ of the disease was multiplied after its entrance into the body.

The Section then adjourned, to meet on Wednesday at 2.30 P.M.

WEDNESDAY, JUNE 6TH—SECOND DAY.

THE Section was called to order by the Chairman, DR. HOLLISTER, at 3 P.M.

DR. THOMAS N. REYNOLDS, of Detroit, Mich., read a paper on

THE ALIMENTARY CANAL IN BRONCHITIS AND PHTHISIS.

He argued that the abnormal condition of the alimentary canal and portal and lacteal systems was often the predisposing cause of both acute and chronic affections in all parts of the respiratory apparatus. Acute tracheo-bronchitis was often caused by excess in the dietary, with proportionately incomplete waste elimination. In view of this fact in such cases the treatment should be prompt evacuation of the bowels and restriction of the diet to a light liquid form. Necessary quiet and warmth of the surface should be maintained, but the atmosphere of the room should not be too warm. The cathartic, hot drinks and warm surface produced a revulsion of nervous energy from the inflamed part to the bowels, kidneys, and skin. He deprecated the use of ordinary cough mixtures to the exclusion of this more rational treatment. Morphine, quinine, aconite, and veratrum viride were the more usually appropriate remedies in the first stage, but did not equal the treatment without drugs to which he referred. Derangement of the primæ and secundæ was still more causative

of chronic bronchitis, and treatment should have reference to this fact.

When purulent, quinine was the best remedy in connection with the management pertaining to ingestion and elimination. It was not wise to press stimulants and strong nourishment when not readily digested. Clothing should be sufficient but not excessive. A common mistake was wearing too much on the chest. He had a few times seen striking improvements in expectoration in those going about from removing two or three extra undershirts and a chamois leather lung protector. Physical exercise, involving free use of the lungs, restored wonderfully their normal elasticity after an attack. It dissipated thickening and adhesions just as continued free motion dissipated the thickening and adhesions from around a recently inflamed joint. Catarrhal fibroid phthyses most frequently were the result of neglected chronic bronchitis and should be treated in much the same way, not by cod-liver oil or any other supposed specific alone, especially if they interfered with digestion, but quinine was useful in lowering the temperature and lessening the secretion of pus. The patient should cultivate an out-door life with plenty of physical exercise and wholesome mental occupation.

Under this régime digestion and tissue-building soon went on properly, cavities often healed, and recovery became complete. Any region free from malaria or unwholesome emanations, with a temperature permitting constant out-door life, would answer for a resort. Tubercular phthisis had sometimes seemed to be excited in those of tubercular family history by neglected bronchitis; in those of constipated habit, and with general defective elimination, and who lived an inactive in-door life. In dyspepsia with constipation, and septic fermentation of the ingesta, it seemed probable that the septic product might be carried by the portal and lacteal vessels directly to the capillaries of the lungs, and be there sometimes auxiliary in causing bronchitis and phthisis in any or all of their forms.

DR. W. F. BELFIELD, of Illinois, followed with a paper on

THE GERM THEORY OF DISEASE, WITH MICRO-PHOTOGRAPHIC ILLUSTRATIONS.

The paper was briefly discussed by Drs. Austin Flint, Jr., of New York City, and A. B. Palmer, of Ann Arbor, Michigan.

DR. JOHN V. SHOEMAKER, of Philadelphia, read a very interesting paper on

MECHANICAL REMEDIES IN THE TREATMENT OF SKIN DISEASES.

These remedies were massage, compression, blood-letting, incision, excision, enucleation, scooping, scraping, setons, and cauterization.

The use of massage in certain morbid conditions of the integument, when properly applied, is often followed with marked beneficial changes, and, at times, with complete restoration of the part to its natural state. Massage not only acts in this way locally, but by its indirect effect, when used generally, will add tone and vigor to the entire system. Direct as well as indirect action of this powerfully mechanical remedy can thus be put into execution, both for its local and constitutional effect in many skin affections. Massage, if employed in its original sense, would simply imply kneading. It has now a wider and more general use, and includes as well a group of procedures known as friction, pinching manipulations, rolling, and percussion of the different external parts of the body. It can be done with the hand or with the additional aid of some fatty substance, a coarse towel, a hair mitten, or brush. It may be performed also by means of ingenious machines that are now perfected and arranged for doing what the most skilful manipulator can do with his hands. The first, and perhaps the most common form of massage used in the treatment of skin

diseases is friction. Friction can be employed upon the integument either by patients themselves or by a manipulator.

In the dry form of seborrhœa, particularly of the scaly, and in thinning and loss of hair, frictional massage used with moderation stimulates and augments the sluggish circulation, furthers absorption, and imparts tone and vigor to the scalp and hair. In indurated acne and in glandular swellings it arouses the activity of the sluggish and choked-up absorbent vessels, and thus relieves the glandular congestion and the skin again becomes normal, in being soft, supple, and elastic, and free from these lesions. It not only has a local beneficial influence upon the class of affections just named, but likewise often removes or assists in removing, when used over the trunk, many gastric and intestinal disorders which very often keep up the cutaneous irritation. This general effect of frictional massage he had witnessed again and again, in relieving and curing constipation and other functional derangements, which were very often active factors in keeping up acne, rosacea, hyperidrosis, seborrhœa, urticaria, and eczema. It was often efficacious in removing scars, and in cases in which the pigment of the skin was either in excess or deficient in quantity stimulating to renewed activity the absorbents, and assisting again in restoring the parts to their natural state. Massage was an invaluable agent in certain neuroses, and especially in neuralgia and perverted sensibility.

Compression is a most important adjunct in the treatment of herpes, herpes zoster, urticaria, furuncular, and glandular affections, erythema, and eczema. In acute eczema it soothed muscular irritation, toned up the dilated capillaries, and prevented the escape of serosity into the tissues. Again in subacute and chronic eczema it enabled the vessels to remove poured-out products, protected the denuded surface, and excluded the air, which was very stimulating to inflamed and irritable parts, and so moderated diseased action. The doctor here showed a new woven gum-bandage which he has been using in place of ordinary gum bandages, and spoke of its great advantage over the latter for making systematic compression in eczema and other skin affections. In chronic eczema of either the superior or inferior extremity, the use of water or oil dressings and local medication, combined with systematic pressure with the bandage, would generally afford a most excellent result.

Referring to blood-letting, he remarked that the abstraction of blood either as a local or general measure was one of the most powerful anti-phlogistic remedies that could be resorted to in the treatment of skin diseases. It was both a speedy and efficient means of combating and arresting morbid changes of the integuments. It was especially applicable in chronic conditions after medicinal agents had been exhausted in vain attempts to cure many eruptive diseases. Blood might be abstracted either locally from the capillaries or generally from a vein or an artery. In the treatment of cutaneous affections by means of blood-letting, local depletion should be used in the great majority of cases, general blood-letting only being resorted to in very rare instances. Topical blood-letting might be performed by puncturing, scarification, and leeching. The doctor then dwelt upon the abstraction of blood in various diseases, and exhibited his new dermatome and other appliances. Concluding, he spoke also of the great value of the other mechanical means mentioned.

The meeting closed with the delivery of a paper upon
A NEW METHOD OF PROCURING PURE PANCREATIC JUICE.

The speaker illustrated his remarks on a dog, in whose stomach he had created an artificial fistula.

THURSDAY, JUNE 7TH—THIRD DAY.

The first paper was by Dr. J. SOLIS COHEN, of Philadelphia, on

THE ELEMENTS OF PROGNOSIS AND THERAPEUTICS OF LARYNGEAL TUBERCULOSIS.

While acknowledging the truth that the prognosis is always unfavorable in tuberculosis of the larynx, it may be maintained that it is less so in some cases than in others. After citing several cases, he discussed a number of acute varieties occurring in his own practice. "I have reason to believe," said the speaker, "that the course of certain forms of tuberculosis of the larynx may be retarded to such an extent in occasional instances as to start the patient on the road to recovery."

Dr. H. A. MARTIN, of Massachusetts, spoke on

VACCINATION AND PROPAGATION OF VACCINE VIRUS.

He recommended physicians to procure virus from young heifers, not because they are cheaper, but on account of their perfect health. The quantity of virus that can be taken from an animal varies very much. It can be used only once. He had introduced animal vaccination in this country, and would like to see it succeed. He did not speak against the use of vaccine from the arm of a patient, but thought it utterly impossible to secure the desired quantity of it.

Dr. A. T. KYTE, of Ohio, read the closing paper, on the
DIMINUTION OF THE RETARDATION OF THE PULSE IN AORTIC INSUFFICIENCY.

The Section then adjourned.

SECTION ON SURGERY AND ANATOMY.

TUESDAY, JUNE 5TH—FIRST DAY.

This Section met at half-past two o'clock. Chairman, Dr. W. F. PECK, of Davenport, Ia.; Secretary, Dr. PAUL F. EVE, of Nashville, Tenn.

The first paper read was on

THE RADICAL CURE OF HERNIA BY A NEW METHOD,
by Dr. R. A. VANCE, of Cleveland, O.

Referring to oblique inguinal hernia, he spoke of the peculiarity of his method as consisting in bringing together the two lips of the hernial opening by means of a deep-seated suture passed subcutaneously with a semi-circular needle.

In this way he converts the previously wide-open hernial canal into a closed valve, that resists all tendency to allow of a second protrusion.

Dr. D. P. ALLEN, of Cleveland, followed with a paper on

THE COMPARISON OF ANTISEPTIC AND NON-ANTISEPTIC METHODS OF TREATMENT.

His conclusions were as follows:

First.—The fact that the operations in the abdominal cavity succeeded without the spray does not influence the employment of antiseptics with regard to other operations where there is a continued opportunity for infection.

Second.—It would appear that the spray is the least important of all the details in antiseptics, and that if the other details are attended to, proper drainage, dressing, and pressure may, by securing absolute quiet for a wound, avert danger.

Third.—That different methods are of different applications, and that whereas the spray may be most important when opening joints, and in the atmosphere of hospitals with bad hygienic surroundings, flooding might be equally efficient in certain other wounds.

Fourth.—That some prominent antiseptics, such as iodoform, would be most serviceable when other antiseptics are inapplicable, as in the removal of a tongue.

Fifth.—That although there are certain dangers in the use of antiseptics, these are more than equalled by the dangers attendant upon their omission, especially in large hospitals; and that dangers by poisoning are cer-

tainly decreasing as the application of antiseptics is becoming better understood.

Sixth.—That investigation may develop a method of securing antiseptic results less onerous, and devoid of the disadvantages that now surround them.

The various antiseptic methods produce better results than any other method.

DR. MARTIN, of Massachusetts, in opening the discussion, remarked that in fifty years, he believed, Listerism would only be regarded as one of the curiosities of medical literature. By Listerism he must be understood to refer to the "destruction of bacilli," regardless of any other co-existent uncleanness. He believed in

GENERAL CLEANLINESS IN THE TREATMENT OF WOUNDS.

He further referred to Ambrose Pares' experience in French campaigns, where the wounds of the higher officers, who had all possible care and surgical oversight, proved far more fatal on the average than those of the common soldiers, whose injuries remained uncared for for days at a time, lying as they did utterly apart from all assistance at the spot where they happened to fall on the field of battle.

DR. C. B. NANCREDE spoke strongly in favor of Listerism and against Dr. Martin's criticisms.

The next paper, on the "Value of Early and Late Operations in Morbid Growths, especially Malignant," was by DR. S. D. GROSS, of Philadelphia. (This paper having been read before the American Surgical Association, appears in our report of that body. See page 639.)

The Section, after listening to a paper by DR. H. A. MARTIN, of Massachusetts, on the

TREATMENT OF SYNOVIAL DISEASES BY A NEW METHOD, advocating the withdrawal of the synovial fluid by aspiration and the application of the rubber bandage, adjourned.

WEDNESDAY, JUNE 6TH—SECOND DAY.

The Section was called to order at 2.30 P.M. by DR. W. F. PECK, of Iowa, Chairman.

DR. ROBT. NEWMAN, of New York City, read a paper on

THE SURGICAL USE OF ELECTROLYSIS.

The results which he had obtained from its use in stricture of the urethra had been excellent.

DR. JAMES R. TAYLOR, of New York, read portions of an elaborate paper on

FRACTURES OF THE LONG BONES,

which was profusely illustrated by well-executed drawings. The doctor first spoke of fracture of the thigh-bone, which he treats with a saddle made to fit into the perineum, whereby he secures the most perfect comfort possible by any apparatus used for the purpose of counter-extension. This neatly devised little saddle is held in position by a strap running to the head-board on each side, thus securing the limb in an immovable position. By fastening strips of adhesive plaster, previously secured to the leg, to a peculiar spring arrangement attached to the foot of the bed, he can produce any desired degree of extension. The chief advantage of the whole apparatus over all other instruments is the little saddle on which the patient sits, as it were, with comfort, rather than misery, as in most other methods, and the arrangement of springs. The doctor announced himself as positively opposed to the old method of using stones and other suspensory weights to produce extension of the limbs, and then turned his attention to

THE TREATMENT OF FRACTURED RIBS.

He brings the broken ends into place by raising the arms over the head, an original method, by which he claims there is no trouble in adjustment. They are then held in place by a band of adhesive plaster around the

body. He gave original methods of treating broken wrists and collar-bones, illustrating the treatment of the latter with a living example in the person of an Irish laborer of this city, who was suffering from an injury of the kind named.

A paper on the

COMPARATIVE VALUE OF ANTISEPTICS

was read by DR. HENRY O. MARCY, of Boston, Mass., detailing the results of a series of experiments.

DR. L. H. SAYRE, of New York, followed with a paper on "Amputation below the Knee-joint, in Preference to either *Brisement Forcé* or Resection, in Certain Cases of Deformity with Ankylosis," illustrated by two cases. The substance of this has already appeared in THE MEDICAL RECORD, page 527.

DR. E. M. MOORE, of Rochester, N. Y., read a very interesting paper on

THE TREATMENT OF OLD CASES OF COMPOUND DISLOCATION OF THE ULNA

in connection with Colles' fracture. He thinks that in those cases of fracture of the radius known as the Colles fracture there is also dislocation of the styloid extremity of the ulna, which dislocation in many cases is not reduced, and great deformity is the result. At any time within six months from the date of the original injury, he rebreaks the united fracture and attempts a reduction of the dislocation, but when cases are of so long standing as not to permit of breaking the bones, he excises the extremity of the ulna, thus making a useful and movable joint. The discussion which followed was participated in by Dr. Wile, of Connecticut; Dr. S. M. Ross, of Altoona, Pa.; Dr. Quimby, of Jersey City, N. J.; Dr. Kinloch, of South Carolina; Dr. Mudd, of Arkansas, and Dr. C. Redin, of Illinois.

DR. V. H. COFFMAN, of Omaha, Neb., read the last paper of the day on

THE TREATMENT OF TENDER SPINES BY SUBCUTANEOUS INCISIONS.

He took issue with the usual method of treatment in such cases and said the simplest but most effective method, rest always understood, is subcutaneous incision over the seat of that portion of the spine which is implicated. His procedure is to introduce a tenotome at a point below the tender spot, thence passing it to a point above, and then by pressure, as he withdraws it, he cuts down upon the bone, and where tendinous structure is involved he divides the sheath of the tendon or performs longitudinal section of the tendon itself. He also incises the aponeurosis when it is the seat of disease.

The paper gave rise to numerous inquiries and a good deal of discussion, as the practice is a very novel one.

Dr. Coffman was recalled to re-explain his method of making the incision, after which he was kept standing upon the stage for some time answering questions from various physicians relative to his paper.

The Section then adjourned, to meet on Thursday, at 2.30 P.M.

THURSDAY, JUNE 7—THIRD DAY.

The first paper was on

EXCISION OF BOTH HIP-JOINTS,

by W. A. BYRD, of Illinois.

The speaker said that ever since the first suggestion of the removal of the head of the femur, by Charles White, in 1769, for morbus coxarius, and the first execution of it, by Schmalz, in 1816, as stated by Dr. Sayre, or by Anthony White, in 1822, as claimed by Barwell, there had been great diversity of opinion among surgeons in regard to its propriety, a few favoring it, but many condemning it as utterly useless. For, while it might save the life of the patient, it frequently left a miserably deformed being, incapable of locomotion without the aid

of crutches or cane. The chances of cure were no better than if the patient were left to depend upon the slow process of spontaneous exfoliation of the diseased bone, a process generally anticipated by death. Opinions, however, had greatly changed since the number of excisions had become sufficient to compare with the older methods. The Doctor then reported the case of a girl, ten years of age, who, after enduring the operation for the removal of the head and upper portion of the femur, was in due time able to walk without crutches, passing up and down stairs with ease. The operation consisted in an incision two inches above the great trochanter, continued downward, curving behind the great trochanter, and ending five inches below its origin. The soft parts were pulled aside and detached carefully, with the periosteum, from the bone, by means of a dentist's scraper. The head of the bone was brought out through the opening, and, on account of its softened condition, was divided just below the trochanter, there appearing to be no other portion of the bone affected. The dressing was oakum and balsam of Peru. A photograph illustration of this case was shown. He called attention to the time intervening between the attack and the excision of the joint, showing the period to be four months.

Dr. Byrd called attention to the splint used by him, which was first brought to his notice by Dr. Charles T. Parks, of Chicago; but stated that the inventor himself, Dr. W. T. Verity, of Chicago, was present, and called upon him to exhibit and explain his apparatus. Dr. Verity placed upon the platform an upright post, to which he attached a triangular frame made of strips of wood, fastened together by strong strap-iron hinges, and attached to the upright by means of a clamp. From the extremity of this triangle hung, suspended by a strong cord, the wire framework in which the patient lies, capable of adjustment to fit any desired position of the limbs. The triangular frame can also be adjusted at any angle, and can be attached to a door-post, or any such convenient upright. The entire apparatus is very portable, and can be packed up for transportation in a few seconds. While in this condition it requires no wider space than an ordinary violin-box. As the inventor explained point after point, proving the superiority of the apparatus, he was enthusiastically applauded.

Dr. L. HALL SAYRE, of New York, complimented Dr. Verity very highly upon having the correct idea of suspension, but claimed for his father and himself the origination of the principle involved in the construction of every apparatus for suspension.

Dr. MOSES GUNN, of Chicago, emphasized the utility of Dr. Verity's apparatus.

The next paper was by Dr. H. O. MARCY, of Boston, on

THE SURGICAL TREATMENT OF INTESTINAL OBSTRUCTION.

He stated that great triumphs had been achieved during the last decade in abdominal operations, and divided intestinal obstructions into three classes—chronic, late acute, and early acute—either or each of which might be caused by fecal impaction, fibrous or cancerous stricture, intussusception, injuries, etc. The first and most important thing was a prompt and correct diagnosis. He asserted that the aspirator could be used to relieve gaseous distention with almost absolute safety, and that its use is followed by relief, though only palliative and not curative. He mentioned the reduction of gaseous distention of the rectum, recommending, however, that no time be lost in resorting to an operation, as the location of the trouble cannot be accurately known. Dr. Marcy recommended opening the abdominal cavity in the median line, taking care to preserve the utmost cleanliness during the operation. After the obstruction had been removed, the edges of the wound should be brought accurately together, especially the opposed edges of the peritoneum, as the hemorrhage is generally grave.

In opening the discussion Dr. B. A. WATSON, of New Jersey, spoke in very commendatory terms of the method.

Dr. GORDON, of Maine, believed the time would come when physicians would be held criminally responsible for the use of the carbolic acid spray in abdominal surgery. He accepted antiseptic precautions, but not the carbolic acid spray.

Drs. Byrd, of Illinois; Brophy, of Pittsburg; Keller, of Arkansas, and Moore, of New York, also took part in the discussion.

Dr. PREWETT, of Missouri, read a paper on "A New Operation for Ranula."

Dr. RANSOHOFF, of Cincinnati, then spoke on "The Early Use of the Trephine." Drs. Gunn, of Chicago, and Hyde, of New York, expressed their corroboration of the writer's sentiments.

Dr. HENRY J. REYNOLDS, of Orion, Mich., then read a paper on

THE TREATMENT OF STRICTURE OF THE URETHRA.

He said no importance whatever should be attached to the statement by the patient that his stream is full size. The size of the stream may be evidence of the *presence* of stricture, but not of its *non-existence*.

For either large or small calibred stricture he prefers internal cutting and stretching with Otis' instrument to all other methods. He always, however, provides the patient with a full-sized sound, with instruction to pass it every few days for an indefinite length of time.

If the stricture be too small for this instrument, he enlarges sufficiently to admit it, first with Thompson's or Maisonneuve's instrument, and then uses the Otis instrument, carrying the enlargement even beyond the normal calibre to insure the absolute and complete removal of all obstruction, without which the cure is liable not to be permanent; the smallest amount of obstruction or contraction remaining, he claims, will furnish a groundwork for future gleet or contraction, or both.

He then gave a report of several cases treated by different methods, showing the comparative merits of each; among which was a case of extreme stricture involving external perineal urethrotomy without a guide, in which even the prostatic portion was contracted in its anterior part. In this case a pocket an inch deep, and large enough to admit the finger, extended upward and backward in front of the prostate, the septum between which and the urethra he cut across.

Dr. R. B. BONTECUE, of New York, made a few remarks on his method of treatment of cystitis by external urethral section.

Dr. J. H. WARREN, of Boston, followed with his paper on "Tissue Repair, or the Pathology of Subcutaneous Injections in Cases of Hernia." He exhibited an improved syringe that discharges its contents automatically upon the slight pressure of a knob attached to the instrument.

A telegram was read from Dr. Dawson, of Cincinnati, expressing regret at his inability to appear at the sessions of the Surgical Section.

The following papers were read by title and referred to the Committee on Publication: "Syphilitic Mammary Tumors," by Dr. C. C. F. Gay, of New York; "A Form of Inguinal Hernia Liable to be Overlooked," by Dr. A. H. Wilson, of Massachusetts; "On Derrick and Improved Suspensory Apparatus for Suspension in the Application of Plaster Casts, etc.," by Dr. W. T. Verity, of Chicago. The Section then adjourned.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

TUESDAY, JUNE 5TH—FIRST DAY.

This Section met at half-past two o'clock.

Dr. J. K. BARTLETT, of Wisconsin, Chairman, and Dr. G. A. MOSES, of Missouri, Secretary.

The first paper presented was that by DR. W. H. BYFORD, of Chicago, on

CHRONIC INTERO-PELVIC INFLAMMATION.

The terms parametritis and perimetritis are supposed by many to include the whole subject of intero-pelvic inflammation.

These terms are misleading, because, as now often used, they present to the mind the idea that all cases of inflammation not confined to the uterus must belong to one or the other of them. Acute observation teaches the important fact that perimetritis and parametritis usually exist together and are usually complicated with inflammation of the uterus, and not infrequently the ovaries and Fallopian tubes are involved. Chronic pelvic abscess is generally the sequel of acute inflammation, and attains chronicity from the imperfect evacuation of the pus after acute inflammation has terminated in suppuration.

The remedy in such cases is found in surgery, and consists in making a more direct outlet through the vagina, large enough to at once completely evacuate the pus and enable the surgeon to cleanse and disinfect the cavity.

He gave the following summary: First, the sometimes terrible effects of examinations or operations in the pelvis do not often, if ever, take place when there is not a perceptible predisposing inflammation. Second, the inflammation may be so slight as to be easily overlooked. Third, it may be an original condition, the sequence of an acute attack long gone by, or it may be the product of some immediately previous examination or operation, the effects of which have not subsided. Fourth, to avoid the dangers of acute inflammation we should, in making the first examination for pelvic disease, conduct it in such a way as not to give the patient much pain, and when she complains of pain and suffering, desist at the sacrifice of complete diagnosis. Fifth, complaints of much tenderness to the touch or the use of instruments, especially in parous women, is sufficiently diagnostic of inflammation upon which to base treatment for that condition. Sixth, if with such tenderness a thorough examination or an operation is imperative, it should be done under profound anæsthesia. There was no question in his mind that much less danger of ill effects is incurred in making examinations or operations on susceptible subjects under the free use of anæsthetics. Seventh, examinations or operations should not be repeated until the effects of the first have entirely passed off. Eighth, as chronic parametritis is a frequent complication of most of the morbid conditions of the uterus, it should be always inspected and its diagnosis be carefully considered in all cases of metritis. Ninth, when chronic parametritis is present it should be the chief, if not exclusive, object of treatment until removed. Tenth, it is not safe to use the sound, sponge-tent, or intra-uterine stem when there is parametritic inflammation. Eleventh, it is especially dangerous to replace a displaced uterus when it is bound down by inflammatory adhesion, by any means which will overcome its fixedness by force. Twelfth, all local treatment of the uterus must be conducted with the greatest care in all cases where the complication is present.

The next paper was on the subject of

POST-PARTUM POLYPOID TUMORS,

by DR. HENRY G. LANDIS, of Columbus, O. He described four forms: 1, blood polypus; 2, fibrinous coagula, with fragments of placenta and membrane; 3, prematurely detached strips of decidua, with or without clots; 4, hypertrophied patches of decidua.

The writer detailed two cases of the latter kind, very few being on record.

A short discussion ensued on a paper on
THE RESTORATION OF THE PERINEUM BY A NEW METHOD,
by DR. H. O. MARCY, of Massachusetts. He advised the

repair of the perineum by the use of lateral support. This he accomplished by the use of German-silver wire, which possesses elasticity enough to make lateral tension, while the ends are so bent as to each form with the other a sort of safety-pin support, which thus holds the refreshed parts in position.

The last paper read was by DR. R. S. SUTTON, of Pittsburgh, on

ENTEROTOMY AS A COMPLICATION IN OVARIOTOMY OR OÖPHORECTOMY.

He related a case in which he had successfully removed four inches of the small intestine, and spoke of this case as the first successful operation of the kind ever performed in this country. Billroth of Vienna has performed the same operation abroad.

WEDNESDAY, JUNE 6TH—SECOND DAY.

The Section was called to order at half-past two by the Chairman, DR. J. K. BARTLETT, of Wisconsin.

Drs. R. Beverley Cole, of California, and J. Tabor Johnson, of the District of Columbia, who were announced for papers, being absent, the first paper read was by DR. JOHN MORRIS, of Maryland, on the subject:

WHAT MEANS CAN BE JUDICIOUSLY USED TO SHORTEN THE TERM AND LESSEN THE PAINS OF LABOR?

He described lingering labor, dividing it into three stages: First, when the head remains high up; second, when it has descended into the pelvic cavity, but the parts are tense and undilatable; third, when the head of the child impinges on the perineum. He explained the procedures to be used in all these conditions and at what time to employ them. These procedures were, detaching the membrane around the cervix with the finger in the first stages, dilating the os with the pulpy part of the finger and stretching it continuously during each pain; rupturing the membranes, forcible external compression pushing the cervix over the occiput, administration of opium, ergot, but never in first cases, and finally, chloroform. These means all failing, the only alternative was the forceps. The Doctor said that if the means he suggested were employed, laceration of the os and perineum, those *bêtes noir* of modern medical literature, would be obviated and post-partum hemorrhage, that greatest of all complications in labor, would be prevented.

The discussion which followed was participated in by Drs. McClurg, of Pennsylvania; Ghent, of Texas; T. Reamy, of Ohio; Smart, of Michigan; Morton, of Maine; Martin, of Massachusetts; Montgomery, of Pennsylvania; Landis, of Ohio; Humiston, of Ohio; Robinson, of Pennsylvania; and Watkin, of Kentucky.

DR. E. C. DUDLEY, of Chicago, followed with remarks on

THE IMMEDIATE APPLICATION OF SUTURES IN PUERPERAL LACERATION OF THE CERVIX AND PERINEUM.

The paper was ably discussed by Drs. Walker, of Kentucky; E. W. Jenks, of Chicago; John Morris, of Baltimore; G. M. Maughs, of St. Louis, and Wm. Ulrich, of Chester, Pa.

Before the Section adjourned, DR. W. A. TAYLOR, of Cincinnati, offered a voluntary and very interesting report of

A CASE OF LAPARO-ELYTROTOMY.

DR. T. REAMY, of Cincinnati, said the one lesson to be drawn was to make the operation earlier.

DR. MATHER, of Louisville, thought laparo-elytrotomy was better than craniotomy, which had been attempted and could not be completed in the present case. In country districts the operation which should have been done was Cæsarean section, Porro's modification of Cæsarean section, or Mueller's modification of Porro's. The latter showed great success in European hospitals.

DR. REED, of Ohio, referred to a case of labor in a

dwarf, with foot presentation. By the second day the body had been extracted as far as the head by traction. Finding it impossible to remove the head, they separated the body and pulled it away with Hodge's long forceps. He succeeded in getting blades round the head. The woman got well without a bad symptom.

DR. WILLIAMS, of Boston, claims that the high forceps operation was more fatal than abdominal section. He did not agree with Dr. Mathers that Cesarean section was an easier or simpler operation. There was less danger of bleeding in Thomas' operation. Dr. Taylor's case was the ninth reported.

DR. JENKS, of Arkansas, was surprised that some one had not referred to symphysiotomy. Recovery of mothers, sixty per cent.; children, thirty-seven per cent. Not above $2\frac{1}{2}$ of antero-posterior contraction of the pelvis was possible in cases amenable to this operation. Drs. Morisani and Novi, of Italy, have reported many such operations performed successfully.

DR. DUNLAP, of Springfield, O., said that the mortality in such cases was very great. Death, however, teaches us lessons which cannot be learned in any other way. The cause of death was doubtless, in the case reported, delay in performing the operation. He would not condemn the operation, but it should have been performed much earlier than it was. Great care should be taken that suppression, if present, is promptly treated. He performed the operation upon the left side.

DR. DANDRIDGE, of Cincinnati, wished to emphasize the ease with which the operation was performed although all the facilities were poor—great want of light, etc. The left side possesses very decided advantages; the finger of the left hand can be introduced into the vagina and so map out the ground. He did not attach much danger to hemorrhage from wounding the epigastric artery. Another lesson to be drawn is that this operation does not require any special preparation. In this case the operation was put off too long.

Dr. Robert Battey, of Rome, Ga., was announced for a paper on "Battey's Operation—Death from Ether," but was not present.

DR. P. ZENNER, of Ohio, then read a paper on
VALUE OF GYNECOLOGICAL TREATMENT IN HYSTERIA
AND ALLIED AFFECTIONS.

While he acknowledged that the cure of uterine diseases was sometimes followed by relief of the nervous disease, he called attention to the injury occasionally caused by local examination or treatment. Cases were reported, some of which came under his own observation, some reported by others, in which gynecological measures had done direct injury. The manner in which harm can be done, principally of mental origin, was detailed. The author thought, for various reasons mentioned, that the etiological relation between hysterics and uterine disease was not as close as believed by many—a predisposition, often hereditary, was usually at its base. In conclusion, after

WARNING AGAINST THE PROMISCUOUS GYNECOLOGICAL INTERFERENCE

in all hysterical patients, he spoke of general measures to prevent the development of nervous diseases. If hysteria depended on defective nervous organization, Dr. Zenner thought no one had a right to demand of the gynecologist who removes a tumor that he must thereby give his patient that which she never possessed—a healthy nervous system.

ULCERATION OF THE OS UTERI WAS A VERY RARE DISEASE IN THE UNMARRIED,

unless given rise to by the murderous practice of introducing the speculum into the virgin vagina two or three times a week, and injecting caustic solutions. He wished to state that the introduction of the speculum in the virgin vagina by a woman doctor was just as unfortunate in its result as the same examination by a man.

DR. GORDON, of Maine, in the main endorsed Dr. Reamy's views, which were that if the symptoms of unmarried women pointed to uterine disease they should receive precisely the same treatment as in the case of a multipara. There was a morbid sentiment in the other direction. Were girls to endure uterine disease untreated by men physicians because they are unmarried? You will not have done your duty if you do not apply local treatment to girls with nervous symptoms pointing conclusively to the womb.

DR. CATLETT, of Missouri, thought that hysterical symptoms in insane patients (female) did not direct their thoughts to the generative organs.

DR. MAUGHS, of St. Louis, said the great danger of the age was the over-zealousness of gynecologists. He condemned the universal practice of making digital examination for all hysterical symptoms; still very many married women suffer after marriage because they have not been examined before they were married, and treated for the uterine disease which really existed.

DR. CRAWFORD, of Illinois, believed that in nervous disorders due to uterine disease the removal of the local disease was only the first step in the treatment. The cure of the local uterine disorder did not by any means imply the cure of the nervous symptoms.

DR. JENKS thought the chief value of Dr. Zenner's paper consisted in its enforcement upon the specialist of the necessity of general constitutional treatment.

DR. G. M. MAUGHS, of St. Louis, read a paper on "The Midwifery and Gynecology of the Ancients," after which the Section adjourned.

SECTION IN DISEASES OF CHILDREN.

TUESDAY, JUNE 5TH—FIRST DAY.

In the absence of the Chairman, Dr. Blount, of Indiana, DR. EARLE, of Chicago, was elected Chairman *pro tem.*; and in the absence of the Secretary, Dr. Sears, of Texas, DR. BOOTHBY, of Wisconsin, was elected Secretary *pro tem.*

The Chairman *pro tem.* then read a paper on

CEPHALÆMATOMA IN THE NEW-BORN.

The tumor spoken of is a soft, elastic, fluctuating tumor, situated on one of the cranial bones, due to rupture of a blood-vessel between the periosteum and the bone. It is usually noticed upon one of the parietal bones, and it can be detected by the fluctuation present. In the caput succedaneum there is no fluctuation; there is simply a boggy feel, an œdematous and bruised condition of the tissues. There were four difficulties with which it is liable to be confounded: first, the caput succedaneum; second, congenital encephalocele, or hernia cerebri; third, erectile tumors; fourth, craniotabes.

The treatment advocated was letting the tumor alone; nature in a great majority of cases cures this difficulty without any aid from our art. There is a tendency on the part of parents and friends to interfere. Formerly it was regarded as good practice to open these tumors, but the fact that a certain number thus opened were followed by long-continued suppuration and exhaustion, and in some cases death, should deter us from operative interference. The special object of the paper was to call attention to the greater frequency of the difficulty than had heretofore been supposed; also to the four affections with which it is liable to be confounded, and to the fact that in a few cases, where pain, swelling, and tension become very great, it is admissible, indeed the best practice, to open these tumors and treat them antiseptically.

DR. WM. LEE, of Baltimore, said he did not know how craniotabes could be confounded with the above, as it was peculiar to rickets, and had accompanying it the many other symptoms of that trouble, which made it impossible for it to be classed with any other disease.

In regard to treatment of cephalæmatoma, while

many cases get well without any interference, there were cases which unquestionably require surgical procedure.

DR. HARRIS, of Virginia, had probably seen cases of the kind mentioned, but his mind had not before been so strongly impressed with the means of distinguishing between them and cases of caput succedaneum. He thought the points made in the paper deserved careful consideration.

DR. READ, of Cincinnati, referred to a case of cephalæmatoma in which, while the diagnosis was not perfectly clear, the let-alone plan of treatment was recommended; but the parents being anxious, sent for another physician, who lanced the tumor. Hemorrhage followed, and the child died.

DR. BOOTHBY, of Wisconsin, had seen three cases falling under the title of the paper, the first one quite early in his practice, which perhaps was a partial excuse for opening the tumor. No bad consequences, however, followed the operation, and the child lived. In the other two cases he made no interference. He thought it a good general rule to let the misshapen head of the new-born alone, and nature would restore the normal form which existed before parturition.

The paper was referred to the Committee on Publication.

WEDNESDAY, JUNE 6TH—SECOND DAY.

The Section was called to order by the Chairman, DR. R. F. BLOUNT, of Indiana.

DR. ALEXANDER Y. P. GARNET read a paper on

EPIDEMIC JAUNDICE IN CHILDREN.

During the summer of 1881, remarkable for its unprecedented heat for a long period, he had under observation several cases of jaundice, the epidemic confining itself to young children. The author of the paper then reviewed the literature of the subject of jaundice, and followed it with a detailed history of one of the typical cases which came under his observation. The epidemic occurred in midsummer, after an unusually protracted period of high temperature, and in all the instances the jaundice appeared before gastro-intestinal disturbance became a marked feature. Dr. Garnet then referred to the usual causes of jaundice, directing special attention to gastro-intestinal catarrh, and expressed the opinion that in the cases in the epidemic referred to, this catarrh was not the real factor in the etiology, because the jaundice antedated the gastric disturbance. He believed that the essential element in the production of the jaundice was an affection of the nervous system, and quoted various authorities at some length to sustain that position. He then asked the question, In what manner does the deleterious agent of heat operate upon the nerves distributed to the liver to effect such a derangement of its normal function? The answer was that scientific research and experimentation had not yet supplied us with positive data upon which we can base a conclusive reply to this question.

UNITY OF DIPHTHERIA AND MEMBRANOUS CROUP.

DR. A. HARRIS, of Virginia, read a paper on the above subject, in which he expressed the opinion that the diseases which have received the name of diphtheria and membranous croup are one and essentially the same. The paper contained extensive references to the opinions of various medical authorities upon this question.

DR. SNOW, of Michigan, believed that the two affections were essentially distinct. Diphtheria begins within a small space, and extends from that location over the mucous membrane. Croup never does this. It commences in the air-passages, almost always over the mucous membrane of the larynx, appearing as a very thin layer of false membrane, which gradually thickens until the child

dies of suffocation. Diphtheria extends as erysipelas does in a measure; it begins and travels on, commencing in the pharynx and going down into the larynx. Diphtheria is a decidedly contagious disease, while croup is not regarded as a contagious disease.

DR. WM. LEE, of Baltimore, said that he was a firm believer that there were two diseases. He differed from Dr. Snow with regard to the direction in which diphtheria had a tendency to spread, and said that according to his observation diphtheria has a tendency to pass up into the nose, and he regarded this as an important diagnostic symptom. In most cases which he had seen the patients had died from blood-poisoning, and in many instances had died from neglect in early treatment, sufficient care not being taken to cleanse the throat, especially behind the uvula. A child with diphtheria might die of croup. He believed, however, that diphtheria was essentially a local disease at first, and constitutional secondarily. Dr. Lee directed especial attention to the fact that albumen is present in the urine in diphtheria and absent in croup. The plan of treatment, according to his experience, which had been most successful was the free use of alcoholic stimulants and quinine. The following remedy he had been using with marked success, and he gave the recipe, for some of the most important items of which he was indebted to Dr. Read, of Savannah, Ga., in order that the members of the Section might have an opportunity to try it during the coming year.

R. Resorcin		gr. x.
Acid. tannic		3 j.
Acid. salicylic		3 iv.
Acid. boracic		3 ij.
Sulph. pulv		3 ss.

Mix thoroughly, and put a small pinch of this powder on the tongue every two or three hours.

The subject was discussed by Drs. Boothby, of Wisconsin; Franklin, of Ohio; Freeman, of Indiana; Sheehan, of New York; Earle, of Chicago; Green, of Ohio, and Ulrich, of Pennsylvania. There was about an equal division of opinion with reference to the unity or the duality of the diseases. Dr. Ulrich and Dr. Snow spoke very highly of the beneficial effects produced by the administration of calomel in large doses; ten-grain doses every two hours. The discussion was closed by Dr. Harris, who reviewed his paper and argued further in support of the opinion that the false membrane is a local expression of the blood-poisoning.

DR. W. H. MYER, of Indiana, then read a paper on

THE SURGICAL TREATMENT OF PURULENT PLEURITIS.

He recommended making a free incision in purulent pleuritis, resorting to puncture only when the effusion was serous. A single puncture was allowable, chiefly for purposes of diagnosis. The reasons for using the knife after the first aspiration were the following: First, the cavity refills after aspiration; second, repetition of aspiration is painful, and causes more or less shock; third, much valuable time is lost by allowing the fluid to remain, and favoring the formation of firm adhesions which will be followed by contraction of the chest; fourth, speedy relief of the lung promotes complete expansion. The admission of air into the pleural cavity has ceased to be an important factor in the operation.

DR. E. SINNOTT, of Ohio, and DR. CHRISTIE, of Iowa, referred to cases which they had treated successfully by the free incision.

DR. C. W. EARLE, of Chicago, then read a paper entitled

A PLEA FOR PLEASANT MEDICATION FOR CHILDREN, AND FOR A MORE THOROUGH STUDY OF INFANTILE THERAPEUTICS.

The Section then adjourned, to meet at 2 P.M. on Thursday.

THURSDAY, JUNE 7TH—THIRD DAY.

The Section convened at 2 P.M., and the first paper was read by DR. A. H. GOOD, of Indiana, on

DENTITION.

In addition to the teeth acting as a foreign body, a reflex nervous irritability is produced. When the gums are swollen they should be divided to relieve pressure, pain, and inflammatory action. Aphthous ulcers should be treated with a solution of persulphate of iron, or some other astringent lotion. For the functional and concomitant derangement of the stomach and bowels, the result of enervation, he uses cold compresses to the abdomen and ice-water injections, and for the secondary symptoms pepsin, bismuth, and carbolic acid.

PÆDIATRIC MEDICATION.

DR. B. CASSEBEER, of Auburn, Ind., read a paper on the above subject, in which he spoke of the judgment necessary in administering medicine to children, and of the necessity of giving as little as possible. He described his experience in making the medicaments palatable. He pointed out that the relation existing between diseases of children and that of adults was as that of the sprout to the full-grown tree. He conjured the profession to wake up to the realization of the fact that there is real science in the proper practice of medicine among the children, where the nature, expression, and influence of disease is read by the physical signs and rational symptoms, unaided by the verbal language of the patients, and that any indifference or inclination to shift responsibility of their treatment is only an evidence of weakness in the physician. The author directed especial attention to the lack of knowledge or misconception of the true principles of the practice of medicine as applied to children. He maintained that diseases of children and adults are essentially alike; that they have been presented in a way in text-books and by teachers as though they were different conditions; that the indications are the same for treatment in children as in adults. Special attention was directed to the treatment of pneumonia and pleurisy.

The general principles of the paper were discussed by Drs. Ulrich, of Pennsylvania; Boothby, of Wisconsin; Van Klein, of Ohio, and others.

DR. TEAL, of Indiana, then read a paper on

INFANTILE OR ESSENTIAL PARALYSIS.

He detailed the history of a case; a female child, seventeen months old. The patient was attacked suddenly. With the best possible treatment this paralysis lasts for a long time, if it is not permanent.

The paper was discussed by Drs. Myers, of Indiana; Sinnott, of Ohio; Snow, of Michigan, and Hyatt, of Ohio.

DR. WILLIAM LEE, of Baltimore, said, as Dr. Teal's paper was confined to a description of what he called paralysis coming on suddenly without any warning whatever, that he believed that these cases, almost as a rule, had as an exciting cause, rheumatism or neuralgia, and this from the fact that the patients get well in a short time under treatment appropriate for these difficulties. Dr. Lee said further, that sometimes the disease seemed to be, as it were, the beginning of hip joint disease, but increase of heat of the parts and other symptoms recognized as due to hip disease easily excluded the disease under discussion. As for the curative treatment of infantile paralysis, he believed that at best it was often unsuccessful, and even when successful was very tedious.

A somewhat protracted discussion on the identity or non-identity of

CROUP AND DIPHTHERIA

was then introduced, and was participated in by nearly all the members of the Section. The symptomatology was reviewed and various plans of treatment of diphtheria

were discussed without developing anything with which the profession in general is not already familiar.

The Section then adjourned.

SECTION IN OPHTHALMOLOGY, OTOTOLOGY, AND LARYNGOLOGY.

TUESDAY, JUNE 5TH—FIRST DAY.

In the absence of the Chairman, Dr. A. W. Calhoun, of Georgia, Dr. J. Chisholm, of Baltimore, was elected Chairman *pro tem*. Dr. Carl Seiler, of Philadelphia, was Secretary.

PARALYSIS OF THE FACIAL NERVE IN CONNECTION WITH DISEASES OF THE EAR.

DR. LAURENCE TURNBULL, of Philadelphia, read a paper on the above subject, in which he directed attention to the fact that acute and chronic disease of the middle ear will give rise to temporary or permanent paralysis, alteration in taste, touch, smell, gait, and vision. Falls, epileptiform convulsions, hemiplegia, and insanity are also due to reflex phenomena from irritation and compression of the sensory and motor nerves of the ear, the result of necrosis of the temporal or mastoid bones. Paralysis of the parts supplied by the facial nerves occur, and are the result of acute inflammation of the ear followed by accumulated secretions in the Fallopian canal, or necrosis of the mastoid cells. Dr. Turnbull then recited the history of several cases which had occurred in the aural department of the Jefferson Medical College Hospital. The first was a case in which a woman, fifty years of age, had a malignant tumor situated in the ear, originally caused by a polypus which gradually extended from the interior of the ear, involving the meatus, auditory canal, temporal bone, and passing out through the auricle until it formed a large double tumor. The lesion was situated between the petrosal branches of the fifth nerve, involving the chorda tympani. It produced perioritis which gave rise to irritation and pressure that ultimately involved the brain and caused death. The second was a case of entire paralysis of the mouth and face, due to exposure and occurring in a patient twenty-four years of age. The patient died within a short time. The histories of other cases were mentioned. This form of paralysis is generally attended by pain, and as the pain is relieved the paralysis shows itself. The pain, however, is not in the facial nerve, but is of a rheumatic character generally, and from some irritation of the fifth nerve. The anatomy of the fifth nerve and its distribution were then given. Dr. Turnbull also referred to cases in which temporary facial paralysis occurred, due to simple swelling of the nerve. Permanent paralysis also of the same nerve might occur in connection with suppuration in the middle ear.

The paper gave rise to discussion, which was participated in by several members of the Section.

DR. J. E. HARPER, of Illinois, then read a paper on

HYSTERIC AMBLYOPIA.

This was followed by a paper on

TONSILLOTOMY WITHOUT HEMORRHAGE,

by DR. WILLIAM C. JARVIS, of New York.

Reference was made to the wide difference in opinion entertained by surgeons of acknowledged authority on the question of hemorrhage following the removal of enlarged tonsils. He named those who discouraged the use of all sharp instruments as dangerous to life, and their opponents in opinion who insisted upon the indiscriminate removal of enlarged tonsils by means of the knife. Safety lay between the two extremes. The histories of two cases selected from a number were given as furnishing the basis for his views. In the first case reported, a profuse and persistent hemorrhage followed the removal of a hypertrophied tonsil excised with the knife. The tonsil presented an unusual appearance. Its

surface was rough, marked with numerous fine indentations, and darker in hue than the surrounding mucous membrane. It had the consistency of cartilage, giving a harsh, gritty sensation when pressed upon.

Afterward another case came under observation where the tonsils were identical in appearance and consistency as the one in which the copious hemorrhage occurred. The scissors and tonsillitome had been used by different surgeons. Alarming and profuse hemorrhage followed each operation. Convinced by the patient's unfortunate history and also by his own experience in operating upon a case of the kind that the knife was contra-indicated, he used the *écraseur*. Both tonsils were removed, each operation occupying three hours. The operations proved bloodless, causing but slight discomfort. When the first was performed the patient said there was no pain, and only complained of the procedure being tedious. Both of the tonsils, though very large, were removed and normal deglutition and respiration re-established. The hemorrhagic and non-hemorrhagic tonsil could, in many cases, be easily differentiated. The hard or scirrhus tonsil differs in many respects from the familiar soft, or malacholic, hypertrophied gland. It lacked the smooth surface, was not easily lobulated, and had not the softness of the familiar glandular hypertrophies. The occasional occurrence of a serious hemorrhage after tonsillotomy not resulting from laceration of contiguous tissues, showed the infrequency with which the harder scirrhus tonsils were met. The two forms of hypertrophy could be easily recognized and distinguished by sight and touch. Preference should be given to the tonsillitome in removing soft malacholic hypertrophies, since like the glandular tissues of the vault of the pharynx the hemorrhage was usually trifling and the pain only momentary. The *écraseur* afforded a safe, simple, and reliable means for the removal of the scirrhus form of enlarged tonsil, which, when excised with the knife, bled invariably like its analogue, the nasal fibroid tumor.

DR. WILLIAMS, of Cincinnati, preferred the bistoury to the guillotine for excising tonsils.

DR. J. P. THOMPSON, of Indianapolis, thought that cutting off tonsils when they were inflamed was not good practice. But in chronic enlargement he had uniformly removed them, and no accidents or unfavorable results had followed the operation. He did not intend to overestimate in the least, but believed that without exaggeration he had excised *two bushels* of tonsils, and thought no special advantage existed in the use of the instrument described.

DR. ROE, of Rochester, had never met with a case of serious hemorrhage after tonsillotomy, although persistent oozing had occurred in several cases. He agreed with Dr. Jarvis that cases should be selected when operative interference was contemplated. Where there is simple hypertrophy, no adhesion to the palatine folds, we are quite safe in not expecting any hemorrhage. But where there are adhesions a small portion of the pillar of the fauces was very apt to be removed, and the liability to serious hemorrhage followed. He uses a peculiar blunt-pointed bistoury and small, long tenaculum forceps. The blade of the knife is about one-fourth of an inch wide and curved. He had also used the tonsillitome. In two or three cases the hemorrhage gave him considerable annoyance. In one of these the hemorrhage was controlled by pressure, and although at times it apparently ceased, removal of pressure was followed by persistent bleeding. Much blood was swallowed and vomiting occurred. The bleeding, he believed, was stopped by the effort at vomiting, from pressure upon the tonsillar artery. This was also recommended by an English surgeon. He has found port wine an excellent styptic for oozing.

THE CHAIRMAN believed that repressed cardiac action resulting from vomiting might explain the cessation of tonsillar hemorrhage.

DR. CARL SEILER, of Philadelphia, had never met

with persistent oozing of blood after tonsillotomy. His patients were given a powder of twenty grains of gallic acid, with thirty grains of tannic acid (a mixture suggested by Mackenzie of London), this to be used should secondary hemorrhage occur. The patients invariably return with the unused powder.

DR. WILLIAM PORTER, of St. Louis, thought the determination of the effect of removal or non-removal of enlarged tonsils was called for as having an important influence upon the patient's career. In his experience local applications had not given good results. The Vienna paste or chromic acid when used mildly was inefficient; if applied as a caustic they proved painful; when applied in stimulating quantity they were apt to increase rather than diminish the hypertrophy. He had used Jarvis' *écraseur* in six cases. Pain was, however, caused by its manipulation in his hands. He had met with profuse hemorrhage in a single case where he had excised the tonsils with a knife. The patient was a physician's child, and the hemorrhage finally ceased without the employment of styptics. Hemorrhage, therefore, may be looked for in certain cases. It was inadvisable to remove the entire tonsil, excision in a line with the pillars of the fauces being sufficient. Hemorrhage most frequently occurs as a result of incision of the faucial pillars. The lessons taught in the paper were valuable and endorsed by him. In view of the opinion gaining ground in favor of Jarvis' *écraseur*, he would use it to remove enlarged tonsils. He also thought that if a small portion of the enlarged tonsil was removed it would be sufficient in most cases, and did not believe there was any special tendency to hemorrhage when the operation was performed in that way.

DR. JARVIS commented upon the good fortune of some of the speakers who had so far met with no serious hemorrhage in removing enlarged tonsils, although it would seem that one of the gentlemen had had a very large experience. He was convinced that they had not met with a scirrhus or hemorrhagic growth. His opportunities for observation had been afforded by one of the largest throat clinics in the country. Out of a large number operated upon, the case described in the paper was the only one in which dangerous hemorrhage occurred. The history of hemorrhage in the other case was obtained from the surgeon who operated. The fact that the tonsillitome was used and only a small portion of the growth excised, showed that the hemorrhage was not caused by laceration of the fauces. Five cases of fatal hemorrhage following incision of the tonsil from puncture of the internal carotid were cited as a warning against the free use of sharp-pointed bistouries. The palatine folds could be incised by even a blunt-pointed bistoury, but not by the tonsillitome. A case of death from exhaustion following the incision of a tonsil by a surgeon using the knife was mentioned, in which death from exhaustion occurred after three days' bleeding.

Cases of nearly fatal hemorrhage, reported by Drs. Geo. M. Lefferts, D. B. Delavan, and Andrew H. Smith, of New York, were referred to. A remarkable tonsillar hemorrhage, published by a physician as occurring in himself, afforded recent and reliable evidence on the subject. Though flushed with success it was well to take timely warning, as a fortunate record was liable to be blighted by the excision of an unnoticed scirrhus hypertrophy. As regards the question of pain asked by Dr. Porter, he called attention to the fact that the patient was permitted to remove the tonsil. Patients by this means can stop, when they feel a twinge, and permit the pain wave to fade away. When the physician removed the tonsil his activity was apt to cause pain.

ACTION OF NITRATE OF SILVER ON THE MUCOUS MEMBRANE OF THE THROAT.

DR. CARL SEILER, of Philadelphia, read a paper on the above subject, in which he stated that nitrate of silver, solid or in solution, is not a caustic; that is, it does

not destroy the epithelial covering, and that its action varies according to the strength of the solution employed. When applied to the surface from which the epithelium has been removed it destroys the upper layer of cells. From clinical observation, the solid stick, or supersaturated, solution does not produce much pain on the healthy mucous membrane, but acts as a local stimulant. Solutions of from two hundred and fifty to one hundred and fifty grains to the ounce act similarly to the solid stick; little or no pain is felt, and the localized inflammation is of but short duration. Solutions of from one hundred and twenty to one hundred and sixty grains to the ounce produce no pain whatever, but, on the contrary, act as a local anæsthetic when applied to the inflamed surface; they produce no perceptible local inflammation, although they stimulate the glandular secretions. These solutions will also frequently cut short acute inflammations. Solutions of less than sixty grains to the ounce produce more pain the weaker they are, and the anæsthetic and astringent action diminish in equal ratio with the strength of the solution, while the stimulant and irritant action increases as the solution becomes weaker. The glandular secretions are materially increased by weak solutions of the salt. When the stimulant and irritant action is desired, the nitrate of silver in fine powder, highly diluted with starch, is preferable to the solution, since the fine granules of the silver salt set up points of inflammation and increased blood-supply.

DR. WM. C. JARVIS, of New York, considered nitrate of silver one of the most valuable of all local applications used in the special treatment of diseases of the throat. The different effects produced by the salt in various forms and parts should be constantly borne in mind. It was unequalled by any other agent in controlling the extension of superficial ulcers of the mouth or pharynx, when used fused or in full strength. Its healing quality in this respect was partly antiseptic in nature, primarily a stimulant, subsequently anæsthetic, and largely protective. When shellac varnish was carefully applied to a superficial sore in the mouth, associated with perversion of the buccal secretions, it would rapidly heal. The silver salt produced the same beneficial result, since the chemical coating or eschar formed protected the ulcer from the action of acrid secretions. This metal, albuminate of silver nitrate, had been shown by experiment to be a most powerful antiseptic. Nitrate of silver did not exercise the same controlling influence over deep ulcers, and was often contra-indicated in the treatment of these lesions. Solutions of the salt were not well borne by the nasal mucous membrane. Catarrhal troubles in the throat and mouth were benefited by sprays containing the salt in solution. It was a valuable application in chronic, congestive, or inflammatory disease of the larynx in the strength of from five to fifty grains to the ounce, the best results being obtained by atomization.

DR. ROE, of Rochester, spoke of the influence of nitrate of silver solution in arresting inflammation in its earliest stages. For example, in acute tonsillitis, a solution of sixty grains to the ounce applied over the surface of the tonsil, and then followed by inhalations of steam, was one of the most valuable methods of treatment for arresting the inflammatory process.

DR. TURNBULL, of Philadelphia, spoke of the local application of the solid stick of nitrate of silver, and also of strong solutions, and had supposed that they produced an eschar; that is, actually destroyed tissue.

DR. CONNOR, of Detroit, thought that the effect produced by nitrate of silver depended very much upon the length of time that the caustic was kept in contact with the surface to which it was applied.

DR. THOMPSON, of Indianapolis, spoke of the beneficial effects which followed the use of nitrate of silver in purulent conjunctivitis.

THE CHAIRMAN thought that he had more than once caused ulceration by applying nitrate of silver about an erysipelatous patch to prevent its spread.

DR. LUNDY, of Detroit, asked Dr. Seiler if he had any method to suggest for removing the stains produced by the use of nitrate of silver.

DR. SEILER, in closing the discussion, said that when nitrate of silver was applied frequently, and for a considerable length of time, there would be a deposit of the substance itself beneath and within the epithelium which would stain the tissues. He knew of no method of removing these stains, because they were produced by the oxide of silver, which is practically insoluble except in cyanide of potassium, which could not be used locally.

With regard to nitrate of silver, either in stick or in solution, producing ulcers and eschars, he could only say that in those cases the local sore was not caused by destruction of the epithelium, but was due to the localized inflammation produced by the fine particles of silver acting as foreign bodies; that is, the stick or the strong solution does not produce the eschar, but the particles of silver set up a localized irritation which produces rapid cell death, the same as does many other substances.

He has never succeeded in removing nasal polypi with nitrate of silver; its application to these growths always caused pain. Has seen microscopic specimens from the eye of a rabbit, showing inflammatory action of the salt upon the intra-ocular tissues. He believed with Dr. Jarvis that location had much to do with the strength in which the silver should be applied.

Benefit could not be derived from using a ten-grain solution of the salt in acute tonsillitis, solutions of from sixty to one hundred and twenty grains to the ounce would cut short the inflammation.

A paper on "Myringitis," by Dr. Williams, of Minnesota, was read by title and referred.

WEDNESDAY, JUNE 6TH—SECOND DAY.

The Section was called to order by DR. CHISHOLM.

The Chairman appointed Drs. Connor, of Detroit; Williams, of Cincinnati; and Seiler, of Philadelphia, as a sub-committee, to which all papers submitted to the Section were to be referred.

SEGMENTAL FEATURE OF GLAUCOMA.

DR. H. CULBERTSON, of Ohio, read a paper on the above subject and reported a case. He believed that glaucoma occasionally showed itself in segmental distribution. The author discussed at some length the pathology of intra-ocular inflammation. A desultory discussion followed, in which the experience of the members of the Section present seemed to sustain the view advanced by the author of the paper.

TINNITUS AURIUM AND THE DEAFNESS WHICH ACCOMPANIES THE DIFFERENT FORMS OF BRIGHT'S DISEASE.

DR. LAURENCE TURNBULL, of Philadelphia, read a paper in which he detailed at length certain aural symptoms frequently accompanying Bright's disease. The drift of the subsequent discussion was that none of these symptoms are pathognomonic of Bright's disease.

DR. J. L. THOMPSON, of Indiana, then read a paper entitled

QUESTIONS ON THE ETIOLOGY OF SOME FORMS OF LENTICULAR OPACITY.

He presented a collection of cases of peculiar opacity of the lower periphery of the lens, appearing suddenly, and lasting for years without change. He could ascertain no cause for this appearance, but had noticed it in diabetic cases.

DR. NOYES, of New York, had seen similar cases associated with myopia. The sense of the discussion was that similar opacities had been observed, due to various causes.

DR. J. O. ROE, of Rochester, then read a paper entitled

NASAL DISEASE THE FREQUENT CAUSE OF ASTHMA.

The discussion seemed to affirm the author's views concerning the production of asthma by nasal irritation.

The Section then adjourned, to meet on Thursday, at 2.30 P.M.

THURSDAY, JUNE 7TH—THIRD DAY.

DR. J. F. RUMBOLD, of St. Louis, read a paper on

THE APPEARANCE OF THE DISEASED MUCOUS MEMBRANE OF THE NOSE AND THROAT OF ADULT PATIENTS.

He described the characteristic appearance of the inflamed throat of the young adult and directed attention to differential diagnosis, prognosis, and treatment. It is unsafe to take the patient's account of symptoms. Follicular inflammation does not require special treatment. The writer had observed cases of aphonia treated successfully by applications to the nasal mucous membrane.

DR. SEILER agreed with the author of the paper as to the possibility of laryngeal trouble being disposed of by nasal treatment. He did not agree with the author of the paper concerning the appearance of the inflamed pharynx, and believed there were more manifest variations. He thought aphonia occurred most frequently about the period of puberty, as did hysterical paralysis in girls and change of voice in boys. He did not agree with Dr. Rumbold concerning the smoker's sore throat, and had found that the throats of cigarette-smokers were more irritated than those of pipe-smokers, as the former inhale the smoke more than do the latter, and there was more surface exposed to irritation. He did not agree as to the harmlessness of inflamed follicles, as touching one of them sometimes produced marked symptoms of violent congestion.

DR. RUMBOLD remarked, in closing, that probably not ten per cent. of the vocal cords of smokers presented their normal white, pearly appearance.

IS ABSCESSION A PROPER OPERATION?

DR. J. J. CHISHOLM, of Baltimore, read a paper with reference to the above question, in which he considered the best mode of forming a stump for an artificial eye. Enucleation is one of the easiest ophthalmic operations; abscission one of the most difficult, and liable to be followed by fatal injury of the ciliary region.

DR. FROTHINGHAM, of Ann Arbor, urged the abandonment of abscission on account of the great liability to the occurrence of secondary inflammation. He considered the difficulty of retaining observation of patients was sometimes a fatal objection in abscission; patients frequently not returning till the cases were beyond hope of successful treatment. He advised enucleation to young practitioners, as the stump is a constant source of danger from the interstitial deposit or morbid growths. The preservation of the stump only for a cosmetic effect should be abandoned.

DR. LUNDY, of Detroit, agreed as to the experience of the author of the paper. Possibly a little better motion of the artificial eye would be obtained by abscission, but the risks overbalance this slight advantage. He gave an instance in which bone had taken the place of the ciliary body; also gave cases in which great sympathetic irritation had occurred. He remembered an unfortunate circumstance in which abscission had been performed and an eye worn on the stump which had eventuated in hopeless blindness.

DR. THOMPSON, of Indiana, mentioned a case of panophthalmitis resulting from abscission; he spoke of care in rounding off the stump carefully, leaving no corners protruding. He mentioned a case of enucleation in which the patient had returned to business on the second day.

DR. CULBERTSON, of Ohio, expressed approbation of

the paper because of its thoroughness, but he had not had an unfavorable result from abscission in thirty years. He never used any sutures after abscission; sometimes has taken out the choroid and retina and allowed the eyeball to take care of itself. By this process he gets not so large a ball, perhaps, but for practical purposes a more useful one. In dividing the tissues well back he cuts off the most sensitive parts of the ciliary nerves.

DR. NOYES, of New York, had performed abscission many times with no trouble, but he always informed the patient of its great danger, and recommended enucleation first.

DR. CORNWELL, of Ohio, related a case in which he had removed the globe with the lachrymal gland and had stitched together the ciliary margins of the lids, putting in drainage-thread, with a fine result.

DR. CHISHOLM, of Maryland, had also abandoned abscission, and laid down as an aphorism, a lost eye is a dangerous element and should be removed.

DR. NOYES mentioned a case of injury to ciliary body.

DR. CULBERTSON, of Ohio, described (having lost the glasses)

A FORM OF SPECTACLES TO BE USED IN LIEU OF NOSE-PIECES.

They consisted of the addition of a semicircular glass to each of the spectacle glasses, attached by a peculiar mechanism, so that the nose-piece allowed them to come below the permanent glasses, out of the way for vision and yet available for close downward vision, as in walking, descending stairs, etc. He gave cases of astigmatic asthenopia and myopic astigmatism which he had relieved by these glasses, and claimed that they were easy of prescription and adjustment.

DR. FROTHINGHAM expressed much regret that the speaker had lost the glasses, and while approving the plan, expressed much doubt as to its practicability and its meeting all the indications as claimed.

DR. CULBERTSON again explained the arrangement of the glasses.

DR. CORNWELL reported four cases: 1, hemianopia without paralytic symptoms, monocular optic neuritis and atrophy of optic nerve; 2, paralysis of the sixth cranial nerve from basilar meningitis; 3, a case of choked disk from tuberculous tumor in cerebellum.

DR. SEILER presented a convenient case of instruments for use at night in emergencies.

DR. TURNBULL read a letter from a patient as to the subject-matter of his paper on Bright's disease.

DR. SCOTT then read a letter from Dr. Calhoun, explaining his absence on account of his wife's sickness.

The Section then adjourned.

SECTION ON DENTAL AND ORAL SURGERY.

DR. D. H. GOODWILLIE, of New York, Chairman;
DR. T. W. BROPHY, of Illinois, Secretary.

DR. JOHN S. MARSHALL, of Illinois, read a paper on

DENUDATION OR EROSION OF THE TEETH.

Various terms had been applied to this disease, such as denudation, erosion, abrasion, surface wear, and atrophy. It consisted in a gradual wasting away of the enamel and dentine, generally upon the labial and buccal surfaces, most often beginning with the incisors, but it might involve all the teeth to the second molars. It usually began at the gums, forming cavities or grooves, which followed the curves of the gum lines. They were smoothly cut and quite sensitive. The disease progressed with variable rapidity; in some cases it seemed to become arrested. John Hunter was the first to notice the condition, and named it "decay by denudation." The views of Bell, Fox, Wedle, Salter, and various others, were reviewed. An interesting case was narrated, in which it was believed there was a syphilitic taint, and

the author then gave his ideas concerning the cause of the affection. The tooth is invested at the root by vital tissues which render it electro-positive; the air surrounding the crown or exposed portion, renders that electro-negative to the root, and forms a negative element, or, in other words, the tooth is polarized. The only thing needed to establish an active current is an acid fluid, and that we have almost constantly in contact with the labial, buccal, and proximal surfaces of the teeth at just the points where the disease manifests itself. It was argued, therefore, that, like the copper wire, the teeth will be acted upon the most vigorously at the junction of its two poles, provided there is an acid medium, like the buccal mucus, to establish and maintain the electro-chemical action. By this action the lime salts are removed at the line of junction and washed away.

Vital resistance, however, was strong, and must exercise a powerful influence over electro-chemical action. The teeth generally denuded belonged to the class called medium, and belonged often to patients who had inherited a peculiar cachexia, as the scrofulous or syphilitic, which had a depressing influence upon the developing processes, and in lowering the vitality. He did not state, however, that syphilis or scrofula produced the disease, but that they predisposed to it.

At the close of the reading of the paper Dr. H. D. Nicoll and Dr. J. H. Hinton, of New York, said they had been informed that the chairman, Dr. Goodwillie, of New York, had not properly registered, and they therefore protested against his acting as chairman of the Section.

DR. WILLIAMS, of Boston, was called to the chair, and Dr. Goodwillie said that he had written to the proper authorities in the Association before he left New York, stating that if there was likely to be any objection raised to his presiding over the Section, he would not go to the trouble of attending the Association. As he was not informed that any objection would be raised, he came and registered, protesting, however, against certain clauses in the qualifications.

DR. NICOLL said that a member of the Judicial Council had informed them that Dr. Goodwillie was allowed to register under protest of the committee, and it was thought that he should not preside over the Section until the Council had taken permanent action in the case. There was some warmth in the discussion following, the members of the Section generally coinciding with the secretary in the statement that parties unknown to the Section should not be allowed to interfere with the regular proceedings of the Section without showing authority for doing so. A member of the Judicial Council came later to enter the protest in a formal manner, but as Dr. Goodwillie, out of courtesy, had not resumed the chair, no further action was taken. Dr. Williams presiding, the Section proceeded to the discussion of Dr. Marshall's paper.

DR. GOODWILLIE thought that erosion of the teeth might be due either to local or constitutional causes, or to the two combined. Scarlet fever, the pustular, and other diseases might check the development of the teeth before maturity, which would be indicated by depressions upon the sides of the teeth. The more compact structure might form over these depressions if vitality was sufficiently restored afterward, or, if not, denudation was likely to result in destruction of the teeth. One of the most important and frequent constitutional affections which lowered the vitality, and led to the condition in question, was syphilis.

The paper was further discussed by Drs. Buffin, Harton, Andrews, Barnes, the Chairman, and others.

On motion of THE SECRETARY, invitation was extended to dentists in general to participate in the discussions throughout the remainder of the session.

Subsequently it was learned that a former Professor in a Homeopathic Medical College had participated in the discussion.

Correspondence.

THE INFLUENCE OF DEAD TEETH UPON THE HEALTH.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: In your issue of the 12th instant you ask a pertinent question as a heading to the interesting letter of Dr. Samuel Sexton upon the subject of dead teeth, to which I beg permission to reply.

The care of such teeth has formed a very large part of my practice for twenty-five years, and I feel competent to speak as to the feasibility of their being rendered, in every instance except where exostosis or malformation is present, quite as durable and innocuous as if their vitality had never become impaired.

A complete misapprehension with respect to this exists among physicians and surgeons, due doubtless to the fact of there being so very few oral surgeons who attend to this branch of dental surgery, and also, I fear, to the peculiar character of the representations made about it by those who do not. It would be easy to have this unfortunate opinion quite changed if those who should be correctly informed would make proper investigations. Certainly the names of such men as Amos Westcott, Robert Arthur, Eleazer Parmley, E. J. Dunning, and Joseph H. Foster cannot be unknown to the medical profession, and there are probably few of the private pupils of those eminent men, or of perhaps others, who could not soon set this question at rest. Would you permit me to ask why such men are not applied to by those most interested in being accurately informed? The proprietors or managers of dental depots could doubtless, if they considered it best to do so, give the names of those who are qualified to fill a root.

Dr. E. J. Dunning is still living, and would give valuable information about it with pleasure, I am sure.

In speaking of the treatment and filling of devitalized teeth, one is necessarily placed at the outset in a very delicate position, since not more, I think, than one oral surgeon in a thousand does it with uniform success, and probably not two in a thousand at all (though I am not referring to the claims made about it), and one does not wish to be considered hypercritical by those who do not. I should be happy to speak of this and, at the same time, pay a merited tribute to the very many conscientious and useful dental surgeons who find the successful care of roots too much for them, but your space would not admit of this.

So kindly pardon me if I reply to Dr. Sexton's letter, not as its importance requires, but by a few plain statements simply.

He does not exaggerate the harmfulness of dead teeth left in the mouth with nerve-cavities unstopped, and with no vent from them for the accumulations which form in them. He is also quite correct in his conclusion, that artificial dentures are not always harmless when fastened to dead roots. The public, which from time to time has its attention directed to this practice in one way and another, would do well not to permit its confidence to be too readily captured. This, however, is not likely, since those wearing such dentures would scarcely speak of the ulceration following their insertion, or of the open pustule too liable to exist, if the roots in question had not been put in proper order by some competent person in the first place.

Nerve-cavities are nests of disease solely from the corruption of the fluids which enter them. Obviously then they are not at all so if the influx of fluids is absolutely prevented. But to stop them in such a manner as to effectually accomplish this object, and it must invariably be done with metal, requires a care in manipulation which can be given it by extremely few mortals only. I know of no manipulation in which human fingers have to engage which approaches it in delicacy. Some years ago

a famous dentist practising abroad, where this is never attempted, came to this country expressly to see a root filled. The operator to whom he applied showed him the process by filling a root for a patient in his presence. Upon its conclusion, and the departure of the patient, he sadly remarked, "I have made my trip to no purpose, for I could never, never accomplish that."

Would you permit me to say, finally and frankly, that it seems to me to be the duty of every physician, surgeon, oculist, and aurist, in every such city as New York, to seek out some oral surgeon who is competent to take proper care of dead teeth and send his patients to him, rather than to permit them to needlessly lose important organs. He should also hold the dentist to the most rigid accountability in case of one single failure, and, if exostosis or malformation does not exist, he should never recommend him for that kind of operation again.

Should Dr. Sexton feel interest enough in this matter to investigate it more fully, I should be happy to have a personal interview with him, and, should he desire it, pray be good enough to give him my name and address.

Your obedient servant,

X.

May 25, 1883.

DR. WALLIAN'S MISQUOTATION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Referring to Prof. Bartholow's disclaimer in your issue of May 19th, I beg to explain that the misquotation occurred through the hasty and fairly inexcusable inadvertence of relying on the statement of one of the numerous handbooks, instead of referring directly to the works of the distinguished author, all of which were within easy reach as I wrote.

In the language of Napoleon, it was "worse than a mistake, it was a *blunder*," and when I add the still more humiliating statement that the guilty handbook referred to was compiled (but not proof-read) by myself (!) I do not know that I can make my apology any more pointed.

It is another lesson to us all, since it proves that we cannot possibly be over-careful or over-accurate in making medical statements or in quoting those of others.

That the statement referred to by Prof. Bartholow was a stupid misquotation occurred to me some days after I had sent you, but too late to recall the report. Hoping to go and sin no more,

Yours very meekly,

SAMUEL S. WALLIAN.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 2, 1883, to June 9, 1883.

ALEXANDER, CHARLES T., Major and Surgeon. So much of S. O. 82, par. 6, A. G. O., April 10, 1883, amended to direct that he be relieved from duty at the U. S. Military Academy, West Point, N. Y., October 1, 1883. S. O. 125, par. 7, A. G. O., June 1, 1883.

McKEE, J. C., Major and Surgeon. Assigned to duty as Post Surgeon, Presidio of San Francisco, Cal. S. O. 56, par. 2, Department of California, May 25, 1883.

DE LOFFRE, A. A., Captain and Assistant Surgeon. To proceed to Madison Barracks, N. Y., and report to the Post Commander for duty. S. O. 98, par. 2, Department of the East, June 5, 1883.

AN IMPROVEMENT IN LITMUS PAPER.—Dr. Squibb has substituted for the ordinary blue and red litmus paper, a single color, viz., purple. This purple litmus paper turns red with acids, blue with alkalis. It is claimed to be much more delicate and convenient.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending June 12, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
June 5, 1883.....	2	7	120	2	120	43	1	0
June 12, 1883.....	0	6	104	4	107	46	0	0
<i>Deaths.</i>								
June 5, 1883.....	0	4	24	2	22	20	0	0
June 12, 1883.....	0	3	23	4	21	18	0	0

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Our report last week stated that Dr. N. S. Davis resigned as trustee to take charge of the department of "Progress in Medicine," etc. This should have read, "Dr. N. S. Davis resigned as trustee, and also announced that *Dr. William Lee*, of Washington, had been secured to take charge of the department of 'Progress in Medicine.'"

AMERICAN MEDICAL EDITORS.—At the annual meeting of the Association, held in Cleveland, June 5th, the following were elected officers for the ensuing year: *President*—Dr. L. Connor, of Detroit; *Vice-President*—Dr. Thomas Gallagher, of Pittsburg; *Secretary*—Dr. John V. Shoemaker, of Philadelphia.

The President, Dr. N. S. Davis, delivered an address on "The Present Status and Tendencies of the Medical Profession and Medical Journalism."

Dr. H. O. Marcy, of Boston, also read an essay on "Journalism Devoted to the Protection and Concentration of Medical and Surgical Science in Special Departments."

A POPULAR THERAPEUTICAL DELUSION.—There is no more common practice than that of giving spirits of nitrous ether as a diuretic. According to Dr. Nunneley and to recent experiments made by Mr. Edmund A. Cook (*British Medical Journal*), nitrous ether is in no sense a diuretic by itself, or a diaphoretic.

A CASE OF TRANSPOSED VISCERA—AUTOPSY.—Dr. W. Fruitnight, of this city, sends us the report of a case of transposed viscera. The patient, a woman aged forty, married, and mother of thirteen children, had been a steady drinker and was discovered to have a cirrhotic liver, diffuse nephritis, and cardiac disease. Of this she died. The following is the record of the autopsy: Lungs: The left one was made up of three lobes. There were evidences of a recent pleurisy on its posterior surface, and a small amount of fluid in the pleural cavity. The right was made up of two lobes. The pleural cavity was obliterated by old general pleuritic adhesions. The structure of both was normal. Heart situated on the right side. It was slightly hypertrophied. The left ventricle was situated on the right side, and *vice versa*. The aortic valve was quite rigid, thickened, and retracted. Pericardium contained about two ounces of serous fluid. Aorta had patches of thickening. It arched toward the right and descended on the right side of the spinal column. Liver weighed 24 ounces. It was situated in the left hypochondriac, lumbar, and epigastric regions, extending three inches below the free border of the ribs in the mammary line. It touched the spleen on the right side. It was divided into two lobes by a deep notch in the anterior border. The left lobe was the largest, and contained

the gall-bladder on its under surface. The surface of the organ was nodulated, and the seat of a decidedly fatty and cirrhotic change. Spleen was located in the right hypochondriac region; its dimensions were 10 by 6 by $3\frac{1}{2}$ inches. It weighed 59 ounces. The enlargement was the result of passive congestion. Stomach was reversed. The cardiac extremity was directed to the right, and the pyloric orifice toward the left. Intestines: The caput coli was situated in the left inguinal region, and the sigmoid flexure occupied the corresponding position on the right side. Kidneys were enlarged, weighing 15 ounces each. They were affected by chronic diffuse inflammatory changes. Pyelitis existed.

THE MEDICINE LAY.—The following ingenious trick is described as having been frequently practised in London. It is known as the "bottle of medicine lay." A healthy vagrant bandages his arm carefully, carries a bottle of water under his coat, collides with a charitable-looking gentleman, drops the bottle with a crash, and attracts a crowd by bemoaning his broken-armed, medicineless, miserable condition. Despite warning, several of these enterprising persons have been carrying on a profitable business and littering the streets with broken glass for some time, until one of them recently rashly lost his medicine twice in the presence of the same gentleman, whose charitable aspect so far belied him that, on the second occasion, he called in the police.

DR. SQUIBB ON PHENIC ACID.—During the past two years (Squibb's *Ephemeris*) very much has been published by "Dr. Déclat, of Paris," on the subject of carbolic acid, or phenic acid as he calls it, for the cure of zymotic diseases, among which he classes phthisis, and most irrational statements are made by him and his advocates in regard to its character and uses. Most of his statements are at variance with well-established facts, and his deductions from these statements are as inaccurate as they are irrational. He seems to have had quite a successful professional following, notwithstanding such absurd statements as that it is impossible to transport pure carbolic acid; it immediately deteriorates and develops cresylic acid, an active poison; it must be combined in its nascent state, and so on. The effect of such undertakings as this of Dr. Déclat seems almost incredible. For all the ordinary uses of carbolic acid as a disinfectant, the next article, or the "crude carbolic acid," is as good or better than the crystals, is much less costly, and is more important because it is so much more largely used. Dr. Squibb recommends very highly a dilute solution of carbolic acid ($\frac{1}{2}$ per cent.) as an application for burns.

HIGHER MEDICAL EDUCATION.—Minnesota has shown a praiseworthy desire to elevate the standard of medical education. We gladly note, therefore, further progress: The faculty of the Medical Department of the Minnesota State University, says the *Northwestern Lancet*, met recently and organized. The President of the University is Ex-officio President of the Medical Department, and P. H. Millard was elected Secretary. This is not a teaching faculty but purely an examining, and the ambition of the gentlemen forming it is to raise the standard of the profession throughout the Northwest. They purpose conferring two degrees, that of Bachelor of Medicine and Doctor of Medicine. Parties desiring to take either of these degrees must have studied four years, attended three courses of lectures, and possess a degree of some college of letters or arts, and not possessing the latter, go before the general University faculty, and pass an examination that would admit him to the Sophomore year of said University. No party can obtain the degree of M.D. without having passed an extra good examination, and defending a thesis before the faculty.

PREMIUM FOR AN INVALID CHAIR.—An Association having the peculiar title of "The Humanitarian Invention Association," Youngstown, O., offers a cash pre-

mium of \$3,000, for the "most complete, practicable, and patentable" invalid chair, for use in homes, hospitals, and public conveyances.

A NOVEL METHOD OF MEDICAL ADVERTISING is described by the *Maryland Medical Journal*: "A few days ago a one-dollar note came to the notice of one of the editors of this journal, on which was stamped 'Doctor A. B. L., Baltimore.' This gentleman is a member of the Medical and Chirurgical Faculty of Maryland."

A KINDLY ACT.—The misfortune which befell Dr. Comegys, of Cincinnati, in not diagnosing a case of small-pox, has brought out the following kindly and interesting letter:

"CINCINNATI, OHIO, May 28, 1883.

"DEAR DR. COMEGYS: We desire to express to you our sympathy for the painful criticism to which you have been subjected in the daily press for having mistaken a case of purpura variolosa for a case of purpura hæmorrhagica, and believe that the report of an almost similar accident which occurred in the hands of three of us, Dr. James Graham and the subscribers, which you may use as you see fit, will at least divide the responsibility among a greater number.

"In this case, which happened seven years ago, the symptoms were so vague and ill-defined, that we felt constrained to regard it as an anomalous case of typhoid fever, and so reported it in the death certificate. On post-mortem examination the lesions were found more like that rare form of disease, purpura variolosa, and we determined to report it as such to the Academy of Medicine of this city. The full account of this case, with the subsequent discussion, is detailed in the *Cincinnati Clinic*, July 15, 1876. We subsequently learned that the body had been in the meantime shipped to some town in the interior of the State.

"We trust that you may take comfort in this evidence of human fallibility, which we share with you in the celebrated aphorism of Voltaire: 'Only the charlatan is always certain.'

"J. T. WHITTAKER,
"P. S. CONNOR."

A SURGEON'S MISFORTUNE.—Dr. Moses Gunn, of Chicago, while conducting a surgical clinic, not long ago, introduced to the class an infant, ten weeks old, who was suffering from a nævus, situated near angle of mouth and about the size of a fifty-cent piece. The child was imperfectly developed, and the growth of the vascular tumor was rapid. The injection of a solution of chloride of iron, a remedy used by Dr. Gunn in many other cases, was selected as a means of relief. Immediately after the injection of three drops of the solution, the child became slightly convulsed and died within thirty minutes. Prof. Gunn's explanation of this unfortunate termination was that the babe died of shock. An inquest was held upon the remains, and Professor Gunn was entirely exonerated, as he should have been. No surgeon passes through his professional life without a certain number of accidents for which he is blameless.

CURIOUS RESULT OF CANNIBALISM IN NEW CALEDONIA.—Mr. J. M. Creed, editor of the *Australasian Medical Gazette*, reports and vouches for the following: In 1848 a man named Sutton, who had been adopted into and was for some time living with the Shuarka tribe of natives in New Caledonia, offended them so seriously, by first leaving it and afterward firing on the messengers who were sent to ask him to return, that watching their opportunity they attacked his camp, situated on an island a short distance outside the territory of the Shuarka chief, killed him, carried off his body, and afterward cooked and ate it, as was the custom of the New Caledonians. To the knowledge of my informant, Sutton had been for some time suffering from venereal disease, and the natives told him that every man who ate of the flesh died shortly afterward, apparently poisoned.

Original Articles.

THE TREATMENT AND CURABILITY OF CHRONIC UTERINE CATARRH.

By PAUL F. MUNDÉ, M.D.,

PROFESSOR OF GYNECOLOGY AT THE NEW YORK POLYCLINIC; GYNECOLOGIST TO MOUNT SINAI HOSPITAL.

THE extreme prevalence and the vital importance of chronic catarrhal inflammation of the uterine cavity, as regards the possibility of conception, as well as the acknowledged difficulty experienced in curing the disease, leads me to offer a few remarks on this subject. I am not aware of having anything particularly new to offer; my object is chiefly to insist on perseverance and on the adoption of thorough measures as absolutely indispensable to success. The causation, pathology, and special symptoms of uterine catarrh do not come within the scope of this paper. The opinion has hitherto largely prevailed, both among specialists and general practitioners, that a really chronic endometritis or endocervicitis (I still use the latter familiar although hybrid term) is practically incurable. This opinion is based partly on the dictum of men of such eminence as Thomas and Sims, and partly on the experience of the numerous physicians who have vainly endeavored to cure this disease by the usual routine of applications, and in a measure also, I presume, on the well-known obstinacy of all forms of catarrhal affections of mucous membranes throughout the human body.

Thomas, in his last edition, says of chronic cervical endometritis, that "Even in the mildest case, which has lasted for some time, from four to six months will probably elapse before perfect cure can be accomplished, and even after this a relapse will be very likely to occur, unless preventive measures be adopted and strictly adhered to. . . . If a large amount of thick resisting mucus hangs from the cervical canal, the prognosis, according to my experience, is very doubtful, and sometimes hopeless, unless very radical measures be adopted."

Of chronic corporeal endometritis he says: "The prognosis . . . is always grave with reference to cure. . . . If it have continued for a number of years it will often prove incurable." And he quotes approvingly the following sentence from Scanzoni: "As for ourselves, we do not remember a single case where we have been able to cure an abundant uterine leucorrhœa of several years' standing."

In opening the discussion on a paper on Intra-uterine Medications, by the late Dr. James P. White, before the American Gynecological Society, in Baltimore, in 1879, Dr. J. Marion Sims remarked that he thought "only a few men can say that they have cured half a dozen of these cases (uterine catarrh with thick albuminous mucus). I am sure that during the first thirty years of my practice I was not able to boast of more than two or three."

Schroeder, of Berlin, has even gone so far, in his efforts to cure this intractable disease, as to practise the complete removal by the knife of the diseased cervical mucous lining and its replacement by vaginal mucous membrane, thereby removing entirely the mucus-secreting power of the cervical cavity.

I could multiply these experiences indefinitely by quoting from all recent authors on gynecological dis-

eases; but I presume it is unnecessary to add further evidence of the intractability of the disease under discussion.

Before proceeding to speak of the treatment and its results, I wish to say a word as to the significance of the disease and the physical conditions under which it occurs.

Significance.—Whether there be a chronic *corporeal* or a chronic *cervical* endometritis, the result as regards conception is usually the same. That desirable event rarely takes place. A thick, glairy, purulent plug of mucus filling and occluding the cervical canal usually effectually bars the cavity proper of the uterus to the spermatozoa. The ingenious hypothesis of Krichteller, of Berlin, that this tenacious cervical plug served as a ladder on which the spermatozoa could climb into the uterus is not borne out by experience.

If the cervical canal is comparatively healthy (and this is rarely the case when its mucous lining has been long exposed to the contaminating influence of the secretions from the cavity above), the presence of a purulent, acrid secretion in the uterine cavity is not favorable to the vitality of the spermatozoa, and, granting that conception actually takes place, the endometrium is scarcely in a suitable condition to receive and nourish the rapidly growing ovum; as a result early abortion frequently occurs.

This baneful influence of chronic uterine catarrh on conception is not imaginary or exaggerated; all will agree that women suffering from this disease are sterile while so affected; and if conception has occasionally taken place, it was rendered possible by the accidental discharge of the cervical plug shortly before coition (possibly by injection, for instance) or by recent treatment. Thus I have known a sterile woman to conceive within twenty-four hours after the removal of the uterine secretions with a cotton-wrapped applicator, no medicated application having been made.

Although sterility is the chief symptom of chronic endometritis, the constant discharge, the subacute vaginitis and vulvitis, frequently entailed by direct contact with the uterine secretions, the menorrhagia not uncommonly produced by the uterine hyperæmia, and the ultimate general anæmia and neurasthenia, are even more distressing and annoying. While acute pain is usually not experienced, many women complain of a sensation of weight, fulness, heat, or burning in the suprapubic and sacral regions, and of bearing-down during walking or standing. One of my patients, a well-known pianist, was unable to continue her daily practising of four to six hours on account of the uncomfortable weight in her pelvic region, after sitting some time on a piano stool, and her sole disease was a profuse chronic cervical catarrh. Another, a young unmarried lady, was nervous, "run down," unable to walk or stand about long, with constant dragging sensations in her pelvis, all produced by the same disease.

That a chronic endometritis will, in course of time, bring about and maintain a chronic hyperæmia of the ovaries, with the distressing symptoms peculiar to that affection, is well known to all gynecologists.

From what I have already said it is evident that the significance of this disease varies accordingly as it occurs in a virgin, a married nullipara, or a woman who has borne children. In a virgin the symptoms are chiefly those produced by the discharge (annoyance, soreness,

pruritus), and by the utero-pelvic hyperæmia. The question of sterility merely looms up for future consideration. Only impending marriage or great distress from the disease should in such cases, as a rule, call for very active radical treatment.

In the married nullipara, however, the sterility will probably be the leading indication for treatment, which should not only look to curing the catarrh, but also to removing any other possible obstacle to conception which may chance to exist (narrow external or internal os, displacement, flexion, ovaritis).

In the parous woman, finally, the question of sterility may or may not preponderate. Indeed, as in such women the cervical catarrh is very often (perhaps usually) due to a gaping of the external os and exposure of the cervical canal produced by laceration of that part during parturition, and the corporeal catarrh frequently accompanies subinvolution, the sterility may be only temporary and may, perhaps, be voluntary. Certain it is, that a thick sanio-purulent mucous plug occluding the cervical canal is quite as sure to entail sterility (at least so long as that plug is not removed) in a parous woman with torn and gaping cervix as in a nullipara. Of course the mucus is more easily dislodged, as by syringing, and sterility is therefore by no means absolute in such cases.

In parous women the enlarged glands and hyperplastic mucous membrane of the cervical canal are frequently exposed by the laceration of the cervix; the so-called ectropion of the endocervical mucosa is present. The diagnosis is therefore an easy one, for the cervical mucus clings to the examining finger, and the eye easily recognizes the condition. But in nulliparous married women it may, at times, be difficult to understand the reason for their sterility, since the finger merely feels a not unusually small external orifice, with rather pulpy borders, and carries none but vaginal mucus with it when it is withdrawn. Here the sound may clear up the case, for on withdrawing it and the guiding finger the familiar thick cervical mucus accompanies it, and on exposing the cervix with the speculum a plug of this same mucus is seen issuing from and clinging to the os, whence it is with difficulty wiped away. The narrow external os, usually found in such cases, entails a retention of the normal cervical discharge; this retention gradually produces a dilatation of the cervical canal, and the accompanying irritation causes hypersecretion, until the cervix assumes a bulbous shape, and its cavity is filled with thick, viscid, discolored fluid. When the external os is dilated by the passage of the sound, and the cervix is compressed by the examining finger, the mucus gushes out in a thick stream. The sound easily detects the presence of a large cavity within the narrow external os. This condition is not at all unfrequent, and is as unfailing a cause of sterility as it is curable by prompt and proper treatment.

While the diagnosis of this disease is easy, and its pernicious influence on the fertility of the female sex is obvious, the question of its successful treatment is by no means so easy of solution. It is to this subject that I particularly wish to invite attention, for cases of this kind occur to the general practitioner probably quite as often as to the gynecologist. I do not propose to discuss all the methods of treatment which have been and may be employed with more or less benefit, but to describe briefly the plan which I have employed for several years, and which I have found to answer fairly well in a majority of my cases.

I may as well begin by saying that it is utterly useless to expect to cure a chronic uterine catarrh by such mild remedies as the plain or even compound tincture of iodine, the solution of nitrate of silver, even one drachm to one ounce, or pure carbolic acid. You will certainly fail in chronic corporeal endometritis, and in the cervical variety you will surely increase the discharge. I have faithfully tried these milder remedies, and have never seen the slightest benefit in the cervical, and but temporary relief in the corporeal variety.

If the patient is a virgin or a nulliparous married woman, it will generally be found necessary, after thoroughly exposing the cervix (in the virgin usually at the expense of the hymen), to enlarge the external os. This is essential for two reasons: first, to give free vent to the accumulated endocervical mucus, and second, to allow the ready application of the remedies. This little operation is best done in the following manner:

The cervix being exposed through a Sims (or after a fashion through a large cylindrical or bivalve) speculum, a Sims uterine knife, or simple bistoury, or straight scissors, is passed about one-fourth of an inch into the cervical canal, and the anterior lip is divided by one quick stroke; the instrument is then turned against the posterior lip and this also is incised, and the same is done with each lateral lip. Four incisions have thus been made, each about one-fourth of an inch deep, completely dividing vaginal and endocervical mucous membrane, and making the external os nearly or quite as large as the calibre of the cervical cavity. In order to insure this opening against speedy closure, it is imperative that the four flaps of mucous membrane formed by this cervical incision be removed. If this is not done, even frequent sounding and forcible dilatation will not prevent the flaps from re-uniting, and in a few weeks the external os is as narrow as ever. I have invariably met with this result when I left the flaps *in situ*, and hence have adopted the plan of seizing each flap with a fine tenaculum and trimming it off with curved scissors, so as to have a funnel-shaped external os. The raw surfaces of this slight wound soon cicatrize over, and the os retains its funnel-shape.

It is not necessary to perform this operation in every nullipara; indeed, in many the discharge has rendered the os patulous, the examining finger easily enters it, and its lips are pulpy and eroded.

I have found the same condition in virgins and married nulliparæ.

After the os has been enlarged, the next step is to destroy, as thoroughly as possible, the cervical glands which furnish the annoying mucous secretion. To do this effectively, once and for all, take a sharp curette, with cutting edge (Sims's or Simon's), and scrape the whole cervical canal up to the internal os until the creaking sound tells you that the subglandular base has been reached. Do not be afraid to do this thoroughly, since no harm can be done, and unless the glands are entirely destroyed, their secreting power is liable to survive. When the whole canal feels smooth, apply, on a cotton-wrapped applicator, or, what is better, a wooden or glass rod, pure nitric acid, being careful to protect the external surface of the cervix and the vagina by packing cotton underneath. This application must be so thorough as to give the cervical canal a charred, yellowish-black appearance, with not even a drop of blood issuing from it. In order to effectually protect the cervix from the acid, I frequently use the cylindrical speculum after curetting. Any excess of acid should be mopped up with cotton, and several tampons covered with vaseline placed against the cervix.

In some instances I have merely applied the iodized phenol (equal parts), or saturated solution of chromic acid. But I prefer the nitric, as more efficient and scarcely more painful. If the patient is a multipara, it is rarely necessary to enlarge the external os; indeed, it is generally lacerated, and more or less gaping. And sprouting from the surface of the everted lips will be found more or less numerous fungoid granulations, which are partly enlarged papillæ, and partly distended follicles. These must be removed in order to cure the hypersecretion, and to put the cervix in proper condition for the plastic operation of Emmet. The sharp curette is here also an excellent instrument, although the curved scissors are often more rapid and efficient in removing large and tough vegetations.

It is these same papillomatous growths which to the

comparatively uneducated touch feel like epithelioma, and give rise to mistaken diagnoses and unfavorable prognoses. A mere clip of the scissors removes them, and leaves a clean, smooth, although raw, surface, which needs only to be attached to its opposite fellow by sutures to effect a cure.

After removing these granulations, the surface should be painted with tr. iodine, or sol. arg. nit. (3 j. to 3 j.), or iod. phenol; or, if the production of a superficial slough appears desirable, nitric acid should be applied, and an emollient tampon inserted.

A very common condition is that of cystic hyperplasia, the everted surfaces being dotted with numerous small translucent, more or less prominent, spots, which are simply occluded cervical glands (Nabothian follicles). Every one of these must be punctured with a bistoury or scarificator, and its cavity obliterated by thorough swabbing with tr. iodine, or it will be a constant source of mucous secretion, and its presence will interfere with union if trachelorrhaphy is performed.

The operation of crucial incision of the external os, followed by the sharp curette and nitric acid to the cervical cavity, had better be performed at the residence of the patient, and the latter kept quietly in bed for a day or two at least. It is not that it is attended by special danger; indeed, I have performed it many times in my office or the dispensary, and seen no bad effects from it. But within the past two years I have met with three instances of unfavorable reaction to this treatment, which has induced me to observe the precautions usually advisable in all operative procedures about the uterus. Two patients upon whom I practised this method at my office during one winter, disregarded my positive directions to go home at once and remain quiet during the remainder of that day, but went down town shopping. It was a cold, damp day, and, as a result, within a few days I was called and found severe pelvic cellulitis, which confined them to their beds for several weeks. During the past winter I scraped away some fungoid granulations from the external os of a patient at Mt. Sinai Hospital, and applied pure nitric acid; she was at once put to bed, but a furious cellulitis ensued which kept her in the hospital for several months. These are the only cases, out of several hundred treated in a similar manner, which have been followed by the slightest unpleasant consequences. I have also curetted the cavity of the uterus proper many, doubtless several hundred, times, and in perhaps twenty cases have swabbed it out with pure nitric acid; in only one instance did a cellulitis follow. I am inclined from this experience to look upon the cervical canal as rather more susceptible to inflammatory reaction from this operation than the uterine cavity, especially when a severe caustic, like nitric acid, is applied; and I believe this greater liability to be due to the intimate relation of the cervix to the lymphatics which abound in the paracervical cellular tissue. While applications above the internal os are more liable to produce shock and peritonitis, those to the cervix are more frequently followed by inflammation of the pelvic cellular tissue.

In spite of this danger, the severe measure (sharp curette and nitric acid) is by far the most advisable, because it is the most effectual. I have never as yet found it necessary to substitute the actual cautery, so warmly recommended by Sims; but I have resolved in the very next case which proves rebellious to the acid to use the Paquelin long slender tip, and thoroughly sear the cervical cavity up to the internal os. The danger of thereby contracting the latter orifice should be borne in mind.

As for catarrh of the endometrium proper, I seldom use the sharp curette above the internal os, except when it is my purpose to remove vegetations or hyperplastic mucous membrane of unusual exuberance, or where the dull curette has not prevented the return of the disease. And then, also, I am tempted to follow the curette by fuming nitric acid, and have seen none but good results

follow this apparently heroic treatment. But, as a rule, I find the dull curette and milder caustics (iodized phenol, co. tr. iodine, sol. arg. nit. 3 j. to 3 j.) sufficient to effect an improvement.

The soluble gelatine pencils containing these ingredients (except the nit. silver), and also iodoform, sulph. zinc and copper, have at times been beneficial in my practice; but the difficulty occasionally encountered in keeping them in the uterine cavity, and their tendency to produce uterine colic, owing to their frequent insolubility, has somewhat deterred me from using them as often as I should have wished to do. If they are readily soluble (and those made by Mitchell, of Philadelphia, and especially those of Fleischer, of 652 East Sixth Street, in this city, are unusually so), these pencils, by their long contact with the diseased surface, are decidedly preferable to fluid applications. They are retained in the uterus by flat tampons over the external os.

As a rule, I think that where an immediate, positive effect is desired (styptic, astringent, caustic), fluid applications on cotton-wrapped applicators are preferable; where a steady, gradual alterative influence is called for, soluble bougies are indicated.

The nitrate of silver is usually prepared in pencils by fusing with nitrate of potash, in various proportions; it is particularly liable to produce uterine colic in this form, and I have never thus employed it.

An indispensable condition to the safe and effectual application of caustics to the endometrium, is the patulousness of the uterine canal, particularly the internal os. Fortunately this is usually the case, the discharge softening the tissues and dilating the canal. But when nitric acid is to be applied, it is always well to secure a canal of sufficient width to permit the easy insertion up to the fundus of a straight rubber stick wrapped with cotton, and a previous dilatation with a tupelo tent for a couple of hours will attain this end.

Whether the application be made to the whole uterine canal, or to the cervix alone, it must be remembered that the more powerful the caustic the longer will it be before the slough separates; that of nitric acid usually takes from five to seven days; that of iodized phenol or pure carbolic acid, three to four days; that of tincture of iodine two days. Not until the slough has separated should a second application of a milder nature be made. I usually employ a solution of nitrate of silver, one drachm to one ounce; or tincture of iodine, and continue these applications every other day, or twice a week, until the raw surface is glazed over, or a return of the discharge shows that the severe treatment has not been effectual and requires to be repeated wholly or in part. It should be remembered, however, that so long as constant applications of caustic are made to a raw surface, it cannot heal. Hence it is well, after a couple of weeks of steady treatment, to allow the patient a week's rest, in order to give nature a chance to heal the wound; if she then fails we must begin again, and perhaps a third and a fourth time.

That *hot* injections should be steadily used whenever there are no tumors in the vagina need scarcely be mentioned. The vaginal leucorrhœa usually present is very effectually controlled by painting the canal through a cylindrical speculum with a mixture of fluid extract of hydrastis canadensis and glycerine, equal parts, and placing a couple of tampons, soaked in this fluid, into the vagina, to be removed in twenty-four hours. As an injection, a tablespoonful of the plain fluid extract of hydrastis in a pint of water is excellent to continue the more powerful effect of the application just mentioned. I have found this remedy superior to any other astringent in vaginal leucorrhœa, as it can be used undiluted without cauterizing or eroding the vagina or vulva.

Patients with chronic endometritis or endocervicitis should be treated at least twice a week, and usually every other day. The more chronic and aggravated the case the more frequent the treatment. As improvement manifests itself, intermissions of several days, or a week

or two, may be made, in order to test the persistence of the benefit.

I have not referred to the time-honored practice of dilating the uterus with a sponge-tent, and tearing away the hyperplastic glands and mucous membrane when the tent is removed, because the dilatation is more safely accomplished by the tupelo, and the removal of the diseased tissues more thoroughly by the sharp curette. But, when the uterus is unusually enlarged and a decided drastic and alterative effect is desired, the sponge-tent may still be employed and prove beneficial. The usual caustics should follow its application. The forcible dilatation of the whole uterine canal by steel divergent dilators or graduated sounds has proved exceedingly useful in my hands in this disease. Not only does the dilatation allow the easy application of topical agents, but the free exit of fluids and the steady pressure of the dilators in themselves act beneficially on the diseased tissues.

I have not discussed Schroeder's radical operation (above referred to) in detail, because it seems to me so complicated, and, I confess, wrong in principle, as to be applicable only to the otherwise totally incurable cases of endocervicitis. To slit such a cervix up to the vaginal junction and transplant into its cavity vaginal mucous membrane (so entirely different in character from that of the cervical canal) seems doubtful surgery, until every other means have failed. However, the operation is ingenious, and in extreme cases doubtless advisable.

The prognosis as regards permanent cure will always be a doubtful one, so long as some time has not been allowed to elapse since the discharge of the apparently cured patient. A temporary improvement, or even an entire cessation of the discharge, may, in a few weeks or months, be followed by a fresh attack of the disease. This experience is common to chronic catarrhal affections of all mucous membranes. And only by means of constant, unremitting, and long-protracted treatment can a permanent improvement or a CURE be obtained. My experience certainly has furnished me with a fair proportion of cases in which, after several months of the treatment above described, an improvement was obtained of such duration as to leave the patients entirely free from uterine discharge for three and six months. Whether the cure was really permanent afterward, I am unable to say, as such patients who came from a distance were lost sight of; of those living in the city, I infer a permanent cure, since it is fair to suppose that, having once been benefited, they would have returned to me had the disease recurred.

Those cases I have found the most amenable to treatment and the most favorable for a permanent cure, in which the uterine discharge was chiefly maintained by a narrow external or internal os, or where a laceration of the cervix and consequent hyperplasia of the follicles was present. The radical operations for these conditions, as I have described them (removal of diseased glands and papillæ by the curette and caustics, division of the external and internal orifices; and, in given cases, closure of the laceration) usually secured a permanent cure. The most obstinate were those instances of catarrhal endometritis and endocervicitis, in which the external and internal orifices were anatomically normal, and no special hyperplasia of the glands or mucous membrane could be detected. Here all efforts to rest on the normal secreting qualities of the mucous membrane usually proved unavailing and permanent relief seemed hopeless. Where there was a distinct pathological condition or lesion of the orifices or tissues of the uterine canal, the removal of that condition and the restoration of the canal and its walls to the normal state was generally possible, and a permanent cure could with fair certainty be promised. My experience, at all events, does not coincide with that expressed by the words of one of our most eminent gynecologists when giving his opinion on two cases of sterility depending on chronic uterine

catarrh (one endometritis, the other endocervicitis) which recently consulted him, viz.: "This is an instance of that interminable uterine catarrh, which is practically incurable." Both these cases came to me utterly discouraged, and after three months of the treatment here described were discharged, to all appearance cured, having been free from discharge for one month without treatment. Whether they remain so is, of course, another matter. But they were both certainly relieved long enough to give them a chance to conceive, and if this happy event should take place, nature alone could, during the puerperal state, complete the cure. And if this one attempt at relief fails, and after some months the discharge returns, as all catarrhs are liable to do, better success might attend a second course of treatment. It certainly does not seem right to discourage all such patients and deprive them of all hopes of maternity (should they chance to be nulliparæ) when experience has shown us how much good a thorough, persevering course of local treatment will do them.

In making this statement I wish to except that class of cases which have been made a special study by Dr. Noeggerath, viz., latent gonorrhœa in the female, where catarrhal infection (I would like to call it affection, for I do not believe in the frequent venereal transmission of this disease as warmly advocated by Dr. Noeggerath) of the vagina and uterine canal has spread to the tubes, and has thus planted itself beyond the reach of topical, as well as general, medication. These cases, when once chronic, are really incurable, and, if they recover, do so almost in spite of, not in consequence of, treatment. Fortunately these cases are not the majority of those which come under our observation. For them only the last resort of Tait's brilliant operation—the removal of the diseased tubes, generally with the ovaries—remains. And we look forward to the not far distant day when we in this country can point to results as favorable after this operation as those reported by its originator.

The intelligent specialist and the general practitioner need scarcely be told that accompanying anæmia must be suitably treated. The influence of iron and other tonics is as marked in improving the tone and functional power of the uterine mucous membrane as of any other organ of the body. Pelvic plethora should be relieved by saline laxatives, the general circulation stimulated and regulated by massage and active exercise, and active hyperæmia of the sexual organs prevented by abstinence from sexual intercourse, during the local treatment here described. And it certainly must be a desperate case which resists all these measures.

IOWA STATE MEDICAL SOCIETY.—The thirty-first annual meeting of the Iowa State Medical Society was held at Council Bluffs, Iowa, May 16th and 17th. The attendance was very good; fifty new members were admitted during the session. This was the first meeting of the Society held since the plan of dividing the work of the Society into sections was adopted, and consequently there was some friction and confusion, which will be overcome in the future. Creditable work was done in most of the sections.

The annual address of the President, Dr. D. Schofield, was an interesting paper advocating, among other things, further reforms in the organization of the Society; higher standard for medical education; more extended and better accommodations for our insane. Volume V. of "The Transactions" of this Society has been published during the year.

The following officers were elected: *President*—Dr. S. R. Robinson, of West Union; *First Vice-President*—Dr. H. C. Huntsman, of Oskaloosa; *Second Vice-President*—Dr. D. W. Crouse, of Waterloo; *Secretary*—Dr. A. A. Deering, of Boone; *Assistant Secretary*—Dr. A. C. Simonton, of Des Moines; *Treasurer*—Dr. G. R. Skinner, of Cedar Rapids. The Society adjourned to meet in Des Moines in May, 1884.

VACCINATION OBSERVATIONS AND SUGGESTIONS.

By E. F. BRUSH, M.D.,

ATTENDING PHYSICIAN TO THE NEW YORK INFANT ASYLUM.

LIKE many other questions in which the dispute has lain between the profession and the laity, the subject of vaccination has not been advanced by recent literature as it deserves. Those who are capable of writing in regard to the matter take upon themselves the task of defending it from the attacks of that incomprehensible class the anti-vaccinators. These latter say we propagate other diseases and do not protect from small-pox. The burden, therefore, of recent contributions to the journals has been simply to defend the procedure. Thus, while devoting attention to statistics they have lost sight of the surgical aspects.

It is supposed we all know how to vaccinate, and, somehow or other, it has come to be considered that there is no choice between the animal and the humanized virus. Presumably this has come about in a business way, by reason of the numerous vaccine farms which are now worked. Some years ago I vaccinated a child from the arm of another healthy child. The parents told a friend of theirs; this friend told his doctor, "a legalized practitioner," who said it was against the law, and that I ought to be arrested. This, of course, made the parents very uncomfortable, but they had at least one consolation, their child had not a very sore arm, while the advocate of law and animal virus produced a sloughing ulcer on the arm of the child which he denuded of cuticle, a practice, unfortunately, very common, and advocated by some of the dealers in animal vaccine, as every arm thus treated is sure to take, with the loss of a good deal of substance.

Some time ago, I examined the arms of 191 children; the result was striking. I found only 13 children with a well-defined, round scar pitted, and only 1 with two scars, well-defined, round, and pitted; 51 had no marks at all; the remainder had scars of various forms, shapes, and colors. No vaccination had been performed for three months previous, nevertheless some of the arms were still crusted. The majority of the older scars contained cicatrices, long, irregular, varying in dimensions from a quarter of an inch to one inch by two, some had purple ridges in the centre, some red; others had cavities, blue or red; some of these were pitted, in some of them on the edge of the raised cicatrix the puckerings somewhat simulated the appearance of pitting. I took the fifty-one that had no marks and selected six of the most favorable subjects; these I inoculated with animal virus, procured from what was considered a reliable source. Only one vesiculated, of the other five one had a very sore arm, indurated on the third day, which did not follow in any way the regular course. The other four did not respond at all. From the good arm I vaccinated on the eighth day thirteen children with only one failure. I continued at the end of each eighth day, to select another good subject, and from it to vaccinate another group. From the close observation of these fifty-one cases I began my studies regarding the proper mode of performing vaccination.

I prefer humanized virus, for the simple practical reason that one can select the subject, watch the vesicle, and procure the virus at the right time uncontaminated. By humanized virus I mean the bovine virus transmitted through the human subject from arm to arm. And here let me state that too much caution can not be exercised in procuring the primary virus. Last summer I sent by messenger to well-known wholesale druggists in New York City for one dozen points of bovine virus, requesting information as to its source. They informed the messenger that the supply was exhausted but that the points would be sent the following day by mail. This was done, but they neglected to state whence the virus had been derived. The weather being warm I used the points immediately

and wrote to the firm asking for information, and received the following reply: "The vaccine virus we sent you was bovine, and was obtained through Mr. —, of the — Dispensary."

I wrote to Mr. —, of the — Dispensary, asking him whence the virus came, and received from the house physician the following reply: "Your favor of the 5th instant to Mr. — has just been shown me. In reply I have to inform you that this institution has never furnished bovine virus, but has until the last four years largely supplied the humanized. Notwithstanding, the points furnished you were bovine and were obtained from the Board of Health. They were sent you contrary to rule and in violation of good faith, as they were obtained for use here. This was the result of an error." The above correspondence explains the degree of carelessness that exists among the dealers. The twelve points procured as above related contained only three that were successful, and these did not present a good appearance. In one case the vesicle, on the eighth day, presented a decided blue color, containing a dark-colored centre crust; another presented a bright opaque pearl-colored vesicle, not umbilicated; the third was a small pearl-colored vesicle with a slight depression. I did not consider it safe to use lymph from any one of these.

Next after the care in procuring the virus there ought to be a preparatory examination of the subject to be vaccinated. This preliminary examination should be directed to the physical condition, especially in its relation to the state of the skin, and more particularly in the vicinity of the place selected for the introduction of the virus; that is, the skin of itself must not furnish a poison to produce irritation. Gregory, in writing on this subject and comparing vaccination with the inoculation of the small-pox virus, says, "It requires no arguments to prove that a process that is to free the constitution from a poison so active and subtle as that of small-pox should be conducted with at least as much attention as was paid to its introduction into the system." These words, written fifty-two years ago, are still applicable and deserve attention. We send for the virus by mail, and rather than lose it, use it immediately, our only care being that there is an ordinary degree of health. I will point out that it requires more than this when I come to make suggestions as to proper careful vaccination.

There is a degree of watchfulness necessary during the progress of vaccination, which is absolutely as much a matter of security as the process itself. In the early days of vaccination, when more attention was given to the protective process and the vexing questions as to its utility were not absorbing the medical mind as in these latter days, Cross, a noted writer says that you must watch the progress "for revaccination becomes imperatively necessary when the regular vaccine pock is impaired by rubbing or accident, when the system is pre-occupied by any other disease, and where the scar is feeble and not indented."

Notwithstanding the apparently well-authenticated cases of the introduction of syphilis into the system by the process of vaccination, I doubt whether this or any other disease would be conveyed were proper caution exercised. I regard the introduction of specific virus into the system in the light of seed-planting. If I go into a field of corn and carefully remove one sprouting grain of corn, without the admixture of other seeds or matter, and place this grain in my field, nothing but corn will grow from it. If I remove with it a shovelful of dirt with other sprouting seeds, the Lord only knows what the product will be. I know corn, where it grows, and where it will grow. With the same absolute knowledge as to the vaccine vesicle, its time of growth, and its form, there is to me an absolute certainty that I can collect it for my planting and nothing else with it. In the old experiments of Drs. Woodville, Willan, and Ferguson, we learn that if small-pox virus be mixed with vaccine virus small-pox virus only will grow, because after inoculation with small-pox

virus the pustule forms in three days, whereas after the introduction of vaccine virus the vesicle forms in four days. Again, if the vaccine virus is first introduced, and when the vesicle is formed the small-pox virus is introduced, they both grow. If they are placed near enough to coalesce, the matter taken from the respective sides will produce the respective diseases. Now, in the case of syphilis, the shortest known period has been ten days between the introduction of the poison and the appearance of the papule, and in Pallazari's cases of syphilitic inoculation twenty-five days elapsed between the operation and the appearance of the papule. Thus the true and uninterrupted course of the vaccine vesicle can be completed before the syphilitic poison becomes localized.

In regard to the operation of vaccination, there are several things to be borne in mind. In the first case we must make the avenue which we open for the introduction of the virus sufficient for its purpose, then we must guard against the intrusion of any other poisons which menace it, and, in opening this avenue, we must take care to do it in such a manner that it may not of itself generate poison.

Without accurately understanding all these dangers, I, at first, thought the chief danger to be guarded against was the repeated use of the lancet. I sought to avoid this by the use of a cambric needle, in each case throwing the needle away when the operation was complete. I discovered that this did not make the right opening, that is, the incisions were not perfectly healed when the vesicles appeared, and this always interferes with their perfect growth. A dried crust or an unhealed incision occupying the place where the vesicle arises distorts its shape, thus precluding the possibility of knowing whether the vesicle is pursuing a normal course, and likewise sets up a premature inflammatory action.

On making this discovery I came back to the lancet, and find, with rare exceptions, I can always make so light and clean an incision that by the third day it is perfectly healed, and the vesicle has a clear field in which to form, and one can see by the fourth day the number of punctata forming; on the eighth day, when these have coalesced, it can be seen whether the vesicle has the normal round shape, umbilicated centre, and clear uncontaminated lymph. I consider the use of the lancet in the manner described as absolutely, unequivocally necessary for perfect vaccination. I may say that I have relieved my mind of the dangers of contaminating the incision by the lancet in common use by having at hand, when operating, a small bottle of alcohol and a lighted alcohol lamp. I first dip the lancet in the alcohol and wipe it dry with a napkin. I then again dip it in the alcohol and set fire to the adhering spirit. I regard this as better than the employment of carbolic acid as the disinfectant, which might adhere to the lancet and irritate the incision, thus preventing perfect healing by the third day, which, let me reiterate, is absolutely necessary to allow the perfect formation of a vaccine vesicle. As the latest hospital statistics teach us that four well-pitted vaccine marks form the highest point of protection, it is advisable, therefore, to give the child two and let it acquire the other two by adult revaccination.

In operating on infants or children I take a piece of note-paper about an inch wide and three or four inches long; in it I cut two holes one-fourth of an inch in diameter and three-fourths of an inch apart. This I stretch over the part selected to be vaccinated, which throws into relief two disks of skin. By this method I can hold the arm perfectly still, avoid making any accidental cuts, and I find if the incisions bleed freely that when the band is removed the bleeding ceases. Of course I take care never to use the same piece of paper twice. If I find on the eighth day that but one of my disks has taken, with lymph from it I vaccinate the other spot. In this connection it is worthy of remark that the second vesicle on the sixteenth day from the first opera-

tion, appears as old as its parent vesicle, notwithstanding that it commenced more than eight days later.

In regard to the preparatory treatment, I differ somewhat from many authors, who warn us against vaccinating infants suffering from bronchitis, sores behind the ears, eczema of the scalp or nates, etc. I have found cases suffering from eczema in locations removed from the spot where the vaccine virus was introduced to follow a normal course. Of course in these cases of eczema there is more danger of the vesicle being scratched, by reason of the itchiness existing in other locations. But if a vesicle happens to become ruptured by this or other accidents, it must be kept perfectly dry by the application of cotton. By this method every case under my observation followed a normal course. I would not have dared vaccinate such subjects if my reading on the matter had been restricted to modern writers. But I found Thomas, in his work on "Practice," recommends the inoculation of vaccine ichor as a remedy in obstinate ulcers on the arms and chest and in glandular tumors. Without placing much faith in this, I nevertheless thought that if it were safe to vaccinate where these troubles existed, it would be safe to vaccinate in the presence of milder diseases.

One other point in the successful carrying out of proper vaccination is to keep the vesicle and the crust, while it is forming, perfectly dry. Avoid, as you would the introduction of pus itself, the application of oil, water, or any substance that would tend to soften the crust. If the vesicle happens to rupture, put on it dry cotton or a dry rag, and allow it to stay there to come away with the crust. I have seen very deep ulcers formed by the casual habit of putting sweet oil or wet rags on the arm, which softens the crust around its edge, where it is liberated, and being still attached by the centre, it rotates till it is finally loosened from the centre, which is deep down near the bone, and presents deep, nasty-looking caverns.

There are some conditions of the skin not absolutely recognized as diseased which forbid the operation of vaccination. A case in point was that of a boy six years old, whose physical condition seemed perfect but whose skin on the arm was rough, dry, and scaly. The incisions I made for the introduction of the vaccine virus did not heal, but commenced festering on the second day. On the eighth day the arm presented an erysipelatous blush and was quite deeply indurated, but no vesicle had formed. This arm was three weeks in healing. I afterward had the skin rubbed twice daily with sweet oil for some time, and again vaccinated with normal results.

Undoubtedly due to the habit of denuding the arm of cuticle, there exists a lack of knowledge of the normal condition of a vesicle on the eighth day. A rather painful illustration of this fact came to my notice while exhibiting some sketches which I had made of normal and abnormal vaccination results. By way of experiment I took a boy, four years old, with a rough, dry, goose-skin epidermis, who was otherwise well nourished and healthy looking. I simply scarified the arm in the same manner as I do for vaccination, without, however, introducing vaccine virus. The illustration I had made on the tenth day, when the arm was reddened, swollen, and indurated with a flat dark crust in the centre of the reddened portion. This illustration, with some of normal vesicles, was submitted to the inspection of a physician for his opinion as to which was the best. He unhesitatingly selected the illustration presenting the most intense action, namely, the one where no vaccine virus had been introduced. This is not surprising when we read the following passage from an article on vaccination in a recent number of THE RECORD. "The fault cannot be in the method, for I scrape off the epidermis entirely from a square measuring a quarter of an inch or a little more and rub the virus on for at least a minute."

It can hardly be called too fastidious to require the arm in all cases to be washed with Castile soap and dried with a clean towel before being vaccinated.

In removing lymph from a vesicle, the nicest kind of care is required, that nothing but lymph be taken. I may say here that since I have regarded vaccination as the nicest and most delicate operation I am called on to perform, I have not had one single case of enlarged glands, erysipelas, or other bad results following the operation. I ought to add, of course, that I have not operated as extensively as many others. The number of cases on which I base this claim is a little over two hundred. I do not wonder that complications arise in the practice of those who use bovine virus. My friend, Dr. Campbell, related to me, some time ago, that he received a quill from one of the dispensaries in the city, presided over by a physician who sells animal virus, and this quill was stained with blood. It was returned, with a request that a clean one be sent in its place. He received the answer that a little blood was not harmful, as it came from an animal so different from the human. As we sow so shall we reap. I have no doubt the wart-like excrescence that occasionally grows on vaccinated surfaces where the bovine virus is used arises from this admixture of foreign material with the lymph. It occurs to me that some one in authority ought to call the attention of the animal-lymph dealers to the necessity of perfect purity.

There is one careless habit which has done much to bring the procedure of vaccination into disrepute, namely, the careless, thoughtless way by which we account for all eruptions, soreness of the eyes, and the like, which take place during the process. It is also noticeable that many physicians allow mothers to imagine that these things, even when they occur after the vaccination is complete, arise from the introduction of vaccine virus. If we take pains to explain that this is not the case, we shall be doing much to weaken the arguments against vaccination.

IMPERMEABLE STRICTURE OF THE URETHRA SUCCESSFULLY TREATED BY ELECTROLYSIS.

By W. H. DIKEMAN, M.D.,

OLEAN, N. Y.

THE following case of impermeable stricture successfully treated by myself by electrolysis, after the plan of Dr. Newman, of New York, may serve a purpose in giving evidence of the successful treatment by such method:

Mr. F. H. S—, of this city, about thirty-five years ago contracted gonorrhœa. He was treated by strong injections and the usual remedies. In three months, he states, he was cured. About ten years later he commenced to notice irritation while micturating, and at times a stoppage of the stream. Without consulting a physician he purchased a bougie, and with more or less manipulation attempted to force it into the bladder, but failed. In the attempt he caused himself severe pain, and, as he states, considerable bleeding. He undoubtedly ruptured the urethral mucous membrane. From this time his trouble grew worse, and for the last three years he has been unable to either retain or pass his water. He has worn a urinal for three years, as his water dribbled away drop by drop. The irritability of the bladder would cause straining in an attempt to micturate, associated with severe tenesmus, and he was obliged to resort to the use of the stool instead of the chamber vessel. And all these long years of suffering and with these inconveniences of life he has been unable to get relief, because in all this time he has been treated for disease of the kidneys and bladder (by constitutional remedies).

On October 10, 1882, I was called to see him in company with another physician, when I obtained the above history. I found him greatly emaciated and careworn. I advised him as to the immediate necessity of exploring the urethral canal. He did not like the idea, because twenty-five years ago he caused himself so much pain by the use of an urethral instrument. However, he soon

consented to the examination. I picked up a No. 17 French bougie and passed it about one inch into the urethra, when it was arrested. It was withdrawn and a No. 15 was introduced, which passed the first stricture but became arrested about one inch and a half further on. Smaller sizes were each used in succession until a No. 9 was reached, which passed the second stricture but was again arrested by a third at about five inches from the meatus. Having no smaller instruments at hand he was advised to call at the office. A No. 3 French filiform bougie failed to pass this third band. I then advised external urethrotomy or treatment by *electrolysis*. He preferred the latter and the operation was performed as follows: An insulated electrode bougie, with an olive silver end, No. 9 French scale, was introduced, and passed the first and second strictures as on the preceding day, but was arrested again at the third. The negative pole of the McIntosh galvanic battery was connected to the electrode bougie, and the wet sponge of the positive pole was placed on the left thigh. Six cells of the galvanic battery were in operation, and in eighteen minutes it passed through the stricture. But to my surprise it passed but a very short distance when it was arrested by a fourth obstruction. Electrolysis with the six cells was kept up fifteen minutes longer, but failed to pass through the band. As the patient felt somewhat exhausted, the electrode was withdrawn and the patient sent home with the advice to keep perfectly quiet and return again the next day at the same hour.

Next day, October 12th, patient returned in due time, said he felt no bad effects whatever from the operation, but said the electricity made him feel much better and wanted more of the same kind.

To satisfy myself as to whether the fourth stricture band was impermeable or not I again tried to pass the No. 3 French filiform bougie, but failed to pass it through the obstruction. So the treatment by electrolysis was returned to as on preceding day. The current was started with six cells and was gradually increased cell by cell, until twelve cells were in operation. The patient had such great faith in the treatment that he desired I should continue the séance longer than on the preceding day. But with the twelve cells in operation the electrode passed gradually on—it appeared that the fourth band was about one inch in length—and in nineteen minutes it passed into the bladder.

The electrode was withdrawn, and Mr. S— made a stream of water, which he had not done for ten years. He departed rejoicing, with the advice to again remain perfectly quiet on his back, and should he experience any ill effects to let me know.

Next day he returned. There were no ill effects whatever. There was no soreness, no pain, no hemorrhage, no dribbling of urine. He wore no urinal, and for the first time in all these long ten years of an uncontrollable bladder, he had now full control, and when the call of nature demanded he could pass a stream of water.

Each day he reported as feeling better, but as the opening was small, the séance was repeated on October 18th, with an insulated electrode bougie No. 13 French. The bougie was arrested at the first stricture, but with twelve cells of the galvanic battery in operation it passed all four strictures into the bladder in seventeen minutes.

On October 21st a No. 15 French conical sound (Van Buren's) passed easily into the bladder.

October 25th electrolysis was repeated with a No. 17 French insulated electrode bougie, and in thirteen minutes it passed quietly into the bladder.

November 1st he reports as gradually improving and feeling better in every way. The séance was again repeated with a No. 21 French, which passed into the bladder in seven minutes. As he is satisfied with the size of the instrument that now passes into his bladder the treatment will, for the present, be suspended. As he is sixty-five years of age he feels contented and satisfied

that his present condition will safely see him through his remaining days.

November 6th, he again reports. His stream of urine gradually gets larger. A No. 22 French sound passed by its own weight into the bladder, without giving any pain in the least, or detecting any soreness whatever. The patient declares himself perfectly well and is discharged.

In place of the experiment given by Dr. Newman for demonstrating decomposition by electrolysis I would suggest the following simple practical test, which can be performed by any one in a few minutes.

Take a small piece of fresh beefsteak and lay it on an insulated surface. Then with the positive electrode placed on the under surface of the beefsteak and the negative electrode on its upper surface where the decomposition can be watched, the conducting cords are now connected with six cells of the galvanic battery. By close observation in a few seconds the effects of the electrolysis on the tissues will be seen to take place. By continuing the experiment for a few minutes the results will be distinctly appreciable, and we have a most correct idea of what takes place in the treatment of stricture of the urethra by electrolysis.

Progress of Medical Science.

THE HEALING OF WOUNDS OF THE SPLEEN.—Dr. Dannenberg (*St. Petersburger Inaug. Dissertation*) wounded, in various ways, the spleen in fourteen dogs, killed the animals in periods varying from twenty-four hours to one hundred and eight days, and examined numerous specimens microscopically. He sums up the results of his investigations as follows: 1. Incisions into the spleen are prone to rapid union; some amount of gaping occurs only on the surface of the organ. 2. Incisions into the pulp are prone to heal without suppuration. 3. Suppuration of the splenic tissue, in the course of a wound, occurs only as a rare exception. 4. Adhesion of the splenic capsule to the omentum, which develops very rapidly, is one of the conditions leading to healing of wounds of the spleen. 5. Perforating wounds heal slowly, and always through development of granulation-tissue. 6. Punctured wounds heal by the first intention. 7. Amputation wounds of the spleen heal by its adhesion to the omentum, resulting from the formation of connective-tissue between the parts. 8. In the formation of a scar, both the proliferating elements of the splenic pulp and the epithelioid elements of the reticulum take part. 9. Hypertrophy of the subserous layer of the capsule depends on the proliferation of cells of connective-tissue. 10. There is proceeding an extremely active proliferation of capsular epithelioid tissue around the edges of a wound. 11. There is proceeding a complete regeneration of the epithelioid covering on the surface of a cicatrix left by a wound. 12. Under certain conditions common epithelioid cells may undergo transformation into cylindrical and cuboid epithelioid elements.

DIAPHRAGMATIC PLEURISY.—Pleurisy of the diaphragm, or, more strictly speaking, of the supra-diaphragmatic space, is always very difficult to diagnose, physiological symptoms being very incomplete, or altogether wanting. Gueneau de Mussy has indicated some signs which, however, are of good value in elucidating the question in favor of this variety of pleurisy. He discovered that the phrenic nerve is painful to pressure in the accessible points of its course between the two origins of the sterno-mastoid muscle. Also pressure on a circumscribed portion of the epigastric region awakens an acute pain. This spot is situated in a point corresponding to the intersection of two lines—one coming from the external border of the sternum, the other from the osse-

ous part of the tenth rib. Gueneau de Mussy named this point the button of the diaphragm. Thus, whenever a patient is found to present these symptoms, the case, *cateris paribus*, may be safely diagnosed as diaphragmatic pleurisy.—*Cor. Med. Press.*

APOMORPHIA AS A SAFE, CERTAIN, AND QUICK EMETIC.—Dr. Brown writes as follows to the *British Medical Journal*, May 12, 1883: "It has occurred to me, in several cases, to have patients who have been obnoxious to ordinary emetics. The emetic has caused nausea and depression, but no emesis. A few weeks ago, two cases of this kind occurred in my practice. One was a man who had been drinking and eating indigestible food. Domestic emetics had been given, which had produced nausea and ineffectual attempts at vomiting. It occurred to me that apomorphia, used hypodermically, might succeed. I prepared a solution containing a grain of chloride of apomorphia, twenty minims of rectified spirit, and water to two drachms, of which I administered ten minims hypodermically, which equals one-twelfth of a grain. In seven minutes it produced free and copious vomiting. There was no nausea, nor depression, nor intolerance of food. The other case was a man who was a total abstainer. Patient had loaded his stomach with a mass of indigestible food, which had caused acute pain in his stomach. He had tried domestic remedies without success. Pain was so severe, that I was called up at night. The other case having been so successful, I at once administered ten minims of the solution. In two minutes, without any previous nausea or warning, the contents of the stomach were violently ejected on the floor, the patient not having time to get a vessel to vomit into. This was repeated two or three times at short intervals, and the patient had speedy relief. In this case there was no nausea or bad after-effect. From inquiries which I have made, I am convinced that the value of apomorphia as a safe, certain, and quick emetic, is not appreciated because not known. In cases of alcoholic and narcotic poisoning, it is a most valuable remedy, and, judging from my experience in one case, the emesis is delayed a few minutes. In cases of acute gastralgia and convulsions in children due to overloaded stomach, apomorphia will prove a speedy cure. I have given one-sixth of a grain of the drug to children by the mouth without producing any effect whatever."

TREATMENT OF PREMATURE BALDNESS.—In the *Berliner Klin. Wochenschrift*, April 16, 1883, Dr. Lassar discusses the etiology and treatment of early baldness, or alopecia prematura. From observation and experiment upon animals it was found that the disease is contagious, and occurs independently of any general affection or the state of health of the patient. The method of treatment recommended is as follows: The scalp is to be washed every day with tar soap, or soft glycerine soap, or with soap containing sodium iodide; the soap is to be thoroughly applied, and rubbed into the scalp for fifteen minutes. Following this is a warm douche; then by the application of a corrosive sublimate (two parts per one thousand) the hair is dried, and a half per cent. spirit-solution of naphthalene is rubbed into the affected portions. Carbolic or salicylic acid may also be employed if desired. If this treatment be adopted in the early stage, when the hair is just beginning to fall, it has usually proved successful, but it must be kept up for eight weeks or more. The fact that this disease is due to a communicable morbid principle has been brought up in order to show its conveyance by the comb and brush of the barber.

GLYCERINE IN PHTHISIS.—Recently Drs. Jaccoud and Ferrand have been trying glycerine as a substitute for cod-liver oil in phthisis, and with so much success that the former orders it in every case where the oil is not borne, and under its use the patients increase in weight, the cough diminishes, and the dyspnoea is in many instances considerably ameliorated.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 23, 1883.

THE PSYCHOLOGY OF PANICS.

ARE we to have an epidemic of panics? It would almost seem so. Three such have occurred in this city within the year. With the memory of the Brooklyn Bridge horror still fresh there came this past week news of an almost similar disaster in England. The public press has described and pictured everything, and has emphasized the details in the thrilling and affecting style of modern journalism. People are on tiptoe for another panic as soon as the occasion occurs.

A panic is an acute disease of the brain, it belongs to medicine and to morbid psychology. A genuine panic is an insanity of the mass. The activity of the higher centres is suspended, reason is gone, the whole force of volition is turned in one channel, the whole energy of the emotions is translated into fear of danger and desire for safety. The panic-struck are anæsthetic, insensible to injury, ignorant of any sight or sound, or taste or smell, except such as relate to their effort for safety. Man when in panic touches as near as ever he can to the mental condition of a beast. A runaway horse, a frightened flock of sheep, a panic-struck crowd are on the same mental level.

There is no emotion so contagious as that of fear, and no desire so strong, so intimately wrought into our nature as that of self-preservation. Hence the rapidity with which the psychological contagion of the panic spreads itself. The strongest and bravest man becomes tremulous when in a crowd struck with fear. Panics have their predisposing causes. The mind when wrought upon by harrowing recitals of previous disasters, or when made unstable from nervous weakness, or insecure by lack of confidence, is most readily affected. For this reason it seems probable that there is at present a widespread predisposition to panics.

The best prophylactic for a panic is the cultivation of a stable nervous system and of the habit of being mentally prepared for contingencies. Every one should know where the fire-escapes are in the hotel in which he sleeps, or the exits in the theatre which he attends. If each person were to take these precautions it would certainly make a difference in the number and extent of panics.

No doubt the best thing for the individual to do in case of panic is in most cases to remain still. One can not stifle emotion but one can often restrain action,

which latter is the thing that does the harm. In incipient panics, loud noises, a confident speech, music, or any distracting object may still affect the mind and check the tide of feeling before it has yet concentrated upon the single purpose of escape.

The class of men who are least affected by and least liable to panics is doctors. We speak from knowledge. We have seen, in a demonstration before a large medical audience, an explosion occur with a flash of flame, burning ether running down and over the table. There was not a cry nor a stir in the whole audience, the fire was put out by throwing cloths over it, and the demonstration went on. We have often witnessed similar accidents on a smaller scale—and the experience is not infrequent—but never have we heard of a party of physicians panic-struck. The reason is easy to see, every medical man is continually called to meet emergencies and to allay panics on a smaller or larger scale. A doctor who has been called to see infants with sudden attacks of croup, children in convulsions, women in hysterical moods, and the various other pathological factors of domestic upheaval, necessarily requires very extraordinary circumstances for the complete disturbance of his own equilibrium.

HOW TO CARE FOR THE POOR.

AMONG the many perplexing social questions of the day there is probably none that have come to assume an aspect so alarming, an interest so vital, a responsibility so pressing, as that of the relation between the upper and lower classes, the old problem of labor and capital, the Gordian knot of history, baffling the wisest minds, and yielding no solution even to the sword. We in America have of late had the various phases of this subject impressed upon our attention in ways that have served to detract considerably from the effectiveness of that style of eloquence known as "spread-eagle," and which are anything but conducive to complacency in the average patriot. It is a question which certainly affects the "life, liberty, and pursuit of happiness" of each and every one of us; and it is certainly time we should "stop and see where we stand." What are the bottom facts in the case?

Our so-called lower class in America is a motley crowd, as indeed, what class is not, in some degree? Other governments have only to provide for a body of people whose disposition and temperament are perfectly well-defined and understood, whose standing and relations have been practically the same for centuries, and are thoroughly known, who are distinctly identified with the country by all the ties of heredity, and who are impregnated with its social atmosphere. From the very nature of the case, society in America is a mixture of many diverse elements. Our land is open to all. Very naturally, but none the less unfortunately, it has come to be the Mecca of all who have become restless under restraint at home, and who seek freedom from it here. No wonder the old discontent breaks out on finding new, but no less oppressive influences against them in their struggle for subsistence. No wonder despondency succeeds to discontent, and the foreign peasant becomes an American pauper. Another potent factor in the pro-

duction of this deplorable state of affairs is found in the growing adverseness of our own common people to engage in manual labor. Unfitted for the "genteel" employments to which they aspire, they lapse into habits of shiftlessness, which soon develop into absolute apathy under the influence of the pitiable fallacy that "the world owes them a living."

We have, then, an enormous and increasing class of people who are largely dependent on charity, and especially is this true of New York. But, on the other hand, the means of relief are most abundant. The question to be decided is, therefore, plainly this: Are these means of relief insufficient or inadequate for the wants of the poor, or do they fail to accomplish their end by expending their energy in false directions? Plainly the latter. For every honest man will admit that, whatever the number of our charitable institutions, and whatever the activity of charitably disposed persons, for some reason the results are unsatisfactory, and as yet all efforts have failed in securing the greatest possible good to the greatest possible number of those in need. As a result of this widespread feeling of something lacking, there have recently been formed in this and other large cities charity organization societies, and which have already been productive of much good. It is easy to see the advantage of a regular organization in such a field. The aim and scope of these societies are admirably embodied in the "Handbook for Friendly Visitors among the Poor," issued by the Charity Organization Society of New York, and published by G. P. Putnam's Sons, New York, 1883. Every one who is brought into contact with the poor should own this book. Its influence will surely tend to materially lessen that ill-advised and misapplied charity which has proved, in so many cases, a curse rather than a blessing. The gist of the whole subject we find upon the title-page, viz.: "Charity must do five things. 1. Act only upon knowledge got by thorough investigation. 2. Relieve worthy need promptly, fittingly, and tenderly. 3. Prevent unwise alms to the unworthy. 4. Raise into independence every needy person, where this is possible. 5. Make sure that no children grow up to be paupers." Then follow in detail the different chapters, as follows: "General Suggestions to Visitors," "Directions to Visitors," "Quotations" (from eminent philanthropists), "Hints on Domestic Economy," "Sanitary Suggestions," "Legal Suggestions," each subject being tersely but clearly treated. The book gives in plain, concise form what might be termed the "first principles" of charity.

Now all this comes home with peculiar force to the medical profession, for no other class of people are brought into such constant and intimate relations with the poor, and none are more identified with efforts for their relief. Gratuitous services rendered a patient who could possibly pay has certainly a demoralizing effect on his character. The Charity Organization Society have recognized this, and act accordingly; but what is the policy of the profession? Our attention was lately called to a circular letter sent by the New York Society to the different hospitals, describing at length a man who had come to New York for surgical treatment, one who was well able to pay, but who was attempting to pass himself off as utterly destitute. Assuredly a move in the right direction; but what medical man doubts of this

man being able to obtain free treatment, especially if his case be an interesting one. The "interests of humanity," which have of late been so feelingly alluded to, would seem, in the light of such facts, to demand a radical reform in this direction.

NON-PARASITIC PHTHISIS.

DR. FRANZ RIEGEL, of Giessen, has made a contribution to the pathology of phthisis which is of especial interest in view of the present active agitation regarding the subject. Riegel has been and still is a believer in Koch's discovery and in Koch's conclusions regarding the causation of tuberculosis. He has recently reported the histories of two cases of phthisis occurring in diabetic patients. He examined the sputa of both. In the one he found the bacilli of tubercle, as has been done before by Immerman and Rüttimeyer. In the other *no bacilli could be found*, despite more than fifty careful examinations. The patient was a man fifty-two years of age, who had suffered from diabetes for a long time. At the left apex of the lung there was dulness, irregular respiratory sounds and moist râles. The sputa was muco-purulent, and at times small masses were expectorated which were found microscopically to contain fatty degenerated portions of the lung parenchyma. There could hardly be any mistake in the diagnosis. It is equally improbable that the failure to find bacilli was due to lack of skill, since Riegel had frequently made such examinations.

It was concluded, therefore, that there is a form of phthisis in diabetics not due to the bacillus. This conclusion is thought to be strengthened by the opinion which pathologists have already advanced, that there occur in diabetes two forms of phthisis, one a tubercular, the other an ulcerative or catarrhal process.

It will be readily seen that if the disciples of Koch admit the existence of a catarrhal phthisis as a complication of one disease, they must admit also the possibility of its occurring under other circumstances. In other words, we are brought back to the old view that phthisis may have two or even three forms: tubercular, catarrhal, and fibroid.

THE DISGUSTED PARTY.

WE have received from a correspondent the following letter:

"DEAR SIR—Will you not allow me a word in your valuable journal regarding the much-discussed subject of medical ethics. My sympathies have all along been rather for the old Code. I have often read and admired it, and I quite disagree with those who talk so glibly about its 'moral platitudes.' With all respect to your opinions, sir, it seemed to me that we were doing very well with it, and that it might have been let alone, when this question of consultation would probably have settled itself. I came very near joining the printed list of old Code defenders. I am very glad I did not, however, and since the disgraceful trickery at the Academy of Medicine occurred, I have heard of many who regretted signing their names to the document which the leaders in the old Code party have been circulating.

"The fact is, sir, the whole controversy has ceased to

be an ethical one, and has degenerated into a medico-political warfare in which the real issue is forgotten. I would not debase myself by acting under such a leader as the old Code puts forward, even to re-enact the fates of Mount Sinai; neither do I care to join the new Code party, which poses too much as a martyr, and is too much *en rapport* with newspaper men to accord with my old-fashioned notions of what a doctor should do.

"I belong to the disgusted party, and I think that there are many with me. We, the disgusted, do not like the flood of circulars which is being sent us by machine organizations. Their postal cards, asking our personal views, are an impertinence, and their addresses and 'comments' are platitudinous and tiresome. We are practitioners of medicine. We know that what practitioners want is more medical knowledge and skill; and that it doesn't make the difference of a pseudo-bacillus in the doctor's actual work whether there is a long code, a short code, or no code, provided we have the Scriptures.

"Will not THE RECORD use its powerful influence to help along this the

"DISGUSTED PARTY?"

We have published the foregoing, though rather long, because it doubtless does represent, as claimed, a widespread sentiment. In a large measure we agree and sympathize with our correspondent. The seeds of liberality and justice have been sown, and have taken root. They cannot now be destroyed. The issue can be safely left to time.

ALUMINIUM IN THE TREATMENT OF PHTHISIS.

DR. JULIUS PICK, of Pribyslau, announces the successful use of aluminium in the treatment of pulmonary tuberculosis. Aluminium, he states (in the *Wiener Medicinische Wochenschrift*), is one of the most active destroyers of the bacillus of tuberculosis, and assuming that this bacillus is the cause of the disease, the metal in question may be rationally given as a remedy against it. When so administered, it kills the bacillus and takes away the specific character of the disease. If, however, serious organic changes have occurred, the drug will not remedy these; hence, in the later stages of phthisis, when much tissue has been destroyed, we can expect no good from Dr. Pick's treatment.

The method employed by the investigator in question is illustrated by the history of a young man, both of whose lungs revealed the changes of the first stage of phthisis. He was ordered the following:

R. Aluminii metall. 1.00 gramme.
Aluminie hydr.,
Calc. carb. depur. 5.00 gramme.
Gum tragac. q. s

M. Div. in pil. No. 60. Sig. one t.i.d., two hours after eating.

The lime was added to assist in the calcification of the tubercle!

He was also ordered to be rubbed all over twice daily with oil. After eight days the diarrhoea and night-sweats had ceased, the fever had left him, and his appetite returned. He was treated for nine weeks, at the end of

which time he seemed to have nearly, if not entirely, recovered. The average dose of aluminium was about 0.10 gramme daily.

Dr. Pick reports the above case as a sample of what the metal will do. He does not say how many others he has treated. It is evident that he has not proved very much for his new remedy as yet.

THE THERAPEUTICS OF BLUFF.

HE stood by the bedside counting the pulse, counting the respirations. The patient was in advanced life, and was suffering from broncho-pneumonia. "One hundred and six!" was the exclamation, "respirations thirty-six. An increase over last evening of ten pulsations and six respirations. Some slight lividity of the extremities of the fingers. Heart's action a little irregular." Dr. Blank shook his head dubiously: "Mrs. Brown is not so well to-day." A cloud passed over his countenance as he spoke these words; it was noticed by Jane, Thomas, and Susan. A gloomy silence followed. The Cammann bin-aural tube was applied to different parts of the thorax. Subcrepitant ronchi everywhere; small bubbling at the bases. "There is extensive consolidation," he said; "this dull region is stuffed with the products of inflammation. It is a hard tug for breath with the old lady."

The supreme cortical cells of Dr. Blank's cerebrum were evolving this thought: "This patient will die; I shall lose prestige in consequence; I shall lose the patronage of this family."

What shall he do about treatment?

The digitalis does not seem to be working well; there is nausea. The squills, senega, and ipecac do not promote expectoration. There is pain in the head, and he fears that it is caused by the quinine and whiskey. In doubt and uncertainty he tells them to put these medicines on one side, and writes a prescription for some carbonate of ammonia. He directs full doses of this medicament, and then, after starting for home, in his hesitation comes back and advises the family to give only half the dose prescribed. With a heavy heart, which his countenance too plainly shows, he bids the Browns good-morning.

What are Thomas and the Brown girls thinking about at this time? "This man is fairly discouraged. He has done all he can. He has no confidence in his medicines. He has made a complete change, and now is doubtful about the result of the change. He evidently thinks mother is going to die. Mother, too, is discouraged. It is time to try somebody else."

Dr. Blank had hardly arrived home that morning when a messenger brought a note from the Browns, stating that they had made a change; that Dr. Blank might consider this note a note of dismissal; that Dr. Bluff would now take charge of the case.

Dr. Bluff was not in any sense a scientific man, nor had he any skill in the selection of his remedies. He stole a good many useful hints from members of the faculty and young graduates, with whom he now and then held consultations (and with whom he always agreed), but his diagnosis was hap-hazard and his treatment was hap-hazard. He drove fast horses, and would bluster like an English country squire. All this gave him great

popularity. Individuals had been heard to say that they would rather have Bluff's presence in a sick room, if he did nothing more than talk slang, and tell them that they would be able to dance a polka in a few days, than have the most scientific college professor who would give them nauseous medicines, and tell them that their sickness was of a very grave nature.

Dr. Bluff was ushered into the room of the sick Mrs. Brown. The diagnosis and the fearful prognostications of poor Dr. Blank were turned to ridicule. There was nothing the matter with Mrs. B., only "a little stuffing" in the chest. He "would clear out those pipes in less than no time." Whiskey and milk and his white emulsion of ammoniacum was all that was necessary. In less than half an hour the vocabulary of banter and current slang was exhausted. The sick woman was a "daisy," a "blooming rose of Sharon," and a "gay old gal." She had not "got through her *sparking*" yet, and "if the present Mrs. Bluff should ever be taken off, he would improve his opportunity," etc. As for dying—"fiddlesticks! she cannot die with *that* pulse." He would "have her out of that bed scrubbing the kitchen floor before a week."

It is needless to say that the Browns were all delighted with the assurance and the jocoseness of their new family physician, whose encouraging words rallied them to renewed efforts to prolong their parent's existence by often-repeated potions of whiskey and milk.

It is worthy of note, too, that the patient herself for a while felt the invigorating stimulus of a new hope. Although the final result was as Blank predicted, yet there always was a feeling on the part of the Browns that if Bluff had been called a little earlier the result would have been different.

The above is no imaginary picture. Dr. Blank and Dr. Bluff are the prototypes of many men who honor or dishonor our noble profession. The latter will generally be the most popular, if not the most successful.

We do not believe in *bluff*, but encouraging words and smiles are often of real therapeutic value.

BROOKLYN DOCTORS.—The King's County Register (says *Ephemeris*) contains the names of 974 persons who are now authorized to practise medicine here. Of these 765 registered in 1880, the year in which the law took effect. In 1881 the additions reached 104 names. In 1882, 77 registered, and thus far in 1883, 28, making an aggregate of 974, a few of whom are now doubtless dead or removed. The "Medical Register" for 1882-3, which practically embraces the same area, and which registers the names of all persons in the regular profession, contains 488 names, and the active membership list of the County Society has somewhere about 370 names. Hence the legally authorized practitioners number about 974, while the regular profession numbers about 488, or just about one-half of the 974, and a portion of the 488 are determined to destroy all impediments to their consultations with the 486, and this on the ground of liberality and humanity.

THE MEDICAL SOCIETY OF LOUISVILLE is the title of a new organization recently established in Louisville, Ky.

News of the Week.

ANNUAL COMMENCEMENT OF THE LONG ISLAND COLLEGE HOSPITAL.—The twenty-fourth annual Commencement of the Long Island College Hospital, of Brooklyn, took place last week in the Brooklyn Academy of Music. There was a large attendance of ladies and gentlemen. The presentation of candidates for graduation was made by Prof. Jarvis S. Wight, and the Hippocratic oath was administered by Prof. Samuel G. Armor, Dean of the Faculty. William H. Dudley, President of the Collegiate Department, conferred degrees upon fifty graduates. Honors were bestowed upon the ten men who passed the best examination. Mr. Andros P. Chesley, of the graduating class, delivered the valedictory, and the Rev. Dr. Charles H. Hall, of the Church of the Holy Trinity, made an address to the graduates. Among the graduates was a colored man, who is said to be a man of fine education. About twenty-five per cent. of the candidates for graduation were rejected.

FOUNDATION OF A PRIZE IN PHYSIOLOGICAL THERAPEUTICS.—The late Dr. Martin-Domourette has left to the Académie des Sciences forty thousand francs for the foundation of a prize in physiological therapeutics.

THE REPORT OF THE TYPHOID FEVER COMMISSION.—The Commission appointed by the Académie de Médecine to consider the subject of typhoid fever, particularly of the Paris epidemic, have made their report. It is couched in somewhat general terms and really presents nothing novel. It refers the epidemic in question to bad drainage and filth, and it recommends certain measures to the municipal government. Only two members of the Académie disagreed with the conclusions.

THE ILLINOIS HEALTH BOARD AND THE COLLEGES.—We learn that the Illinois State Board of Health is now revising its "Directory of the Institutions Granting Medical Diplomas or Licences in the United States and Canada." Copies of the last issue are being sent to the medical colleges asking for corrections and additions, at the same time reminding the colleges that the schedule of "minimum requirements" as to the good standing of schools in that State is now in force.

JOURNALISTIC CHANGE.—Dr. E. C. Dudley has resigned the editorship of the *Chicago Medical Review*. Dr. Roswell Park has assumed the editorial chair thus vacated.

THE LONDON UNIVERSITY has for the first time given its medical diplomas to women graduates.

AN IMPOSITION.—Doubtless our valued contemporary *The Medical and Surgical Reporter* will unite with us in holding up for reprobation one R. H. Gilliford, who has evidently sent copies of the same article both to the above journal and to *THE RECORD*. We can hardly suppose any contributor so dull and ignorant as not to know that editors accept articles only on condition that no other journal has received the same.

PLACE AUX DAMES.—The remains of two New York ladies were cremated at the Lemoyne Crematory, Washington, Pa., last week.

DONATION TO THE GERMAN DISPENSARY.—Mr. and Mrs. Oswald Ottendorfer will present a new site and a new building with a free circulating library to the German Dispensary of this city. The site is upon Second Avenue at the corner of Eighth Street, the lot being 70 feet by 150. The sum paid for the site was \$62,000, and the building to be erected will cost \$80,000 to \$90,000, making the total amount of this most generous donation about \$150,000.

OFFICERS OF MAINE MEDICAL ASSOCIATION.—The following officers were elected for the ensuing year: *President*—Dr. O. A. Horr, Lewiston; *Vice-Presidents*—Drs. L. W. Pendleton, Portland, and D. E. Marston, Monmouth; *Corresponding Secretary*—Dr. J. O. Webster, Augusta; *Board of Censors*—Drs. H. N. Small, Portland; W. K. Oakes, Auburn; J. M. Bates, Yarmouth; W. B. Cobb, Standish; and J. D. Nutting, Hallowell; *Committee on Publication*—Drs. C. D. Smith, C. O. Hunt, and G. H. Cummings, Portland; C. A. Packard, Bath; and B. F. Sturgis, Auburn; *Business Committee*—Drs. I. E. Kimball, Portland, and W. P. Watson, Gorham. Dr. A. S. Thayer, of Portland, was chosen Treasurer for five years. Dr. C. D. Smith, of Portland, was elected Recording Secretary in 1882 for a term of ten years.

PROFESSOR CHIARI has been made Ordinary Professor of Pathological Anatomy in the University of Prague.

THE GERMAN SOCIETY FOR PUBLIC MEDICINE met in Berlin May 16th to 19th. Virchow took part in some of the debates.

CONSULTATIONS IN GERMANY.—Prince Bismarck is attended in his present illness by Gen. Rath Frerichs, a well-known and reputable physician, in association more or less with a homœopath by the name of Zwingenberg.

On the occasion of a recent attempt to prosecute a quack who was selling homœopathic medicines, Bismarck is reported to have said that he considered the sale and use of homœopathic medicines quite harmless.

MORE VETERINARIANS NEEDED.—In an address before the Kentucky Medical Society, at its recent session, the practice of veterinary surgery was commended to young men. The speaker estimated that the yearly loss arising from the want of sound advice and treatment—the horses of the country being valued at nearly eight hundred million dollars—amounts to \$15,000,000.

A DOCTOR EXONERATED.—A jury of medical men was convened last week to hear the evidence against Police-Surgeon R. H. Vorhees, in a charge of malpractice. A policeman had his foot crushed and died in consequence. The jury brought in the following verdict, which shows the nature of the case:

"We find that policeman Timothy Ryan came to his death from traumatic gangrene and pyæmia, and that in view of the fact that the patient was sixty-seven years of age and had calcification of the arteries, no blame can be attached to any of the surgeons in charge of the case."

THE NEWPORT NATURAL HISTORY SOCIETY is the title of a scientific organization recently established in Newport, R. I. Dr. Samuel W. Francis was the original promoter, and a number of medical men are among the members.

THE FLOATING HOSPITAL OF ST. JOHN'S GUILD will make its first excursion this season on or about June 26th. It has been decided to begin the trips earlier this year, as it has been found that cholera infantum is largely produced during the June heated term. The Sea-side Nursery will also be opened at the same time.

OUR CULTIVATED CONTEMPORARY the *Medical Press and Circular* refers appreciatingly to the Holmes banquet, and says that American medicine may well feel proud of the author of the "Breakfast-table Essays," "Elsie Venner," and the "Bigelow Papers." Perhaps Minister Lowell will make some objection to this view.

ATTENDING THE SICK POOR.—The Sick Children's Mission of the Children's Aid Society has begun its summer work of providing medical attendance, medicine, and nourishment, free of charge, to the sick children of the poor in the tenement-houses. A corps of physicians has been engaged to visit the sick children at their homes. A number of druggists have agreed to put up all prescriptions at a small cost to the Mission.

ANOTHER OPPONENT OF KOCH.—Klebs, of Zurich, has come out against Koch. The Zurich pathologist claims that Koch has not yet proved that his bacilli are organic structures, and that the cultivation experiments are imperfect, since he has not separated the bacilli from the substratum.

THE REVIVAL OF THE PORK PROBLEM in the *North German Gazette*, by attempts to show from statistics that American pork is sixty times more liable to produce trichinosis than German, may, says *The Sun*, give Minister Sargent something more to do. A short time since it was charged in the German newspapers that thirteen deaths had occurred in the garrison at Tilsit from eating American pork, and that many more of the troops were sick. Mr. Sargent caused the nearest consular officer to make an inquiry, and it was found that fourteen trivial cases of trichinosis had occurred, and that every one of the patients had recovered. The statement that American pork is sixty times more trichinosed than German is about twenty times too strong. It is in fact unwarranted by any trustworthy statistics.

THE HONORARY DEGREE OF LL.D., of Cambridge, is to be conferred on M. Pasteur, Sir John Lubbock, and Professor Roscoe.

DR. ROBERT DRUITT, of England, died recently. He is well-known as the author of the "Surgeon's Vade Mecum."

HOMŒOPATHY AND THE MICHIGAN ASYLUM FOR INSANE.—Petitions have been circulated freely among the homœopathic physicians of Michigan, asking the State Legislature to place the medical management of the Northern Michigan Asylum for the Insane in the hands of the homœopaths.

PASSAGE OF A LAW REGULATING THE PRACTICE OF MEDICINE IN WISCONSIN.—Dr. P. H. Millard, President of the Wisconsin State Medical Society, sends us a copy of a law passed at the last session of the Wisconsin Legislature, and entitled "An Act to Regulate the Practice of Medicine in Wisconsin." Dr. Millard writes: "It is quite similar to the Illinois law in many of its features,

and upon the whole, if properly and judiciously enforced, I think a far superior law. There is a general disposition to give the law a fair trial by the profession and much satisfaction in obtaining any law upon this subject. The provisions of the act will be judiciously and rigidly enforced by the Board of Examiners, and we trust will merit the success that it deserves.

"The most objectionable feature of the bill is the five years' exemption clause, but the bill could not have been passed without this provision."

A HOMŒOPATHIC PHYSICIAN OF MINNEAPOLIS has been appointed "Professor of Obstetrics and Gynecology" in the "State University Medical College," a non-teaching faculty appointed by the regents, and constituting, by recent enactment of the Legislature, the examining board for the State.

THE COLLEGE OF THERAPEUTICS is the title of a new medical college recently incorporated in Massachusetts under the general statutes. It is said that the institution has been established in the face of the recent decision of the Assistant Attorney-General that institutions thus incorporated could not confer diplomas.

ENFORCING THE REGISTRATION LAW.—We are glad to learn from the *Buffalo Medical and Surgical Journal* that the Board of Censors of the Erie County Medical Society have undertaken, with commendable earnestness, a crusade against certain persons in that city and county who are imposing upon the credulity of the public by practising medicine without either diploma or license, in violation of the laws of the State.

TRICHINOSIS IN CHICAGO.—The Secretary of the Cattle Commission, J. H. Sanders, has learned that, since his appointment (somewhat over a year), seven cases of trichinosis are known to have occurred in Chicago, of which three were fatal.

ALLEGED PRESENCE OF PLEURO-PNEUMONIA.—The investigations of the Agricultural Department and the local Health Board in Washington appear to show that the outbreak of disease among cows in that city is not due to contagious pleuro-pneumonia, but to simple pneumonia, which is not contagious.

PRIZES OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—No award of the triennial prize of the Royal College of Surgeons having been made this year, the subject has been withdrawn, and the following substituted for the next, to be awarded in 1886, viz., "The Nature of Inhibitory Action in the Animal Body, to be elucidated by Original Research." This prize consists of the John Hunter Medal, executed in gold, to the value of fifty guineas; or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of £50. The subject for the Jacksonian Prize for 1884 is, "The Surgical Treatment of Uterine Tumors, both Innocent and Malignant." For the present year, it is, "The Pathology, Diagnosis, and Treatment of Obstruction of the Intestines in its Various Forms in the Abdominal Cavity." The value of the Jacksonian Prize is about \$60.

OPERATING UPON A PERSON IN ORDER TO DETERMINE THE SEX.—Professor Porro recently performed an operation for no other purpose than to determine the

sex. The individual requiring such unique interference was pseudo-hermaphrodite, aged twenty-two, had been brought up as a female, although all her (his) tasks had been masculine. The face and chest were like those of a man, although the breasts were considerably developed. The pelvis and lower limbs were like those of a woman. The mons veneris was slightly developed. There was a vulva, with a well-developed clitoris labia and a short vagina; no penis, no prostate, and no uterus. At the summit of what corresponded with the labia majora, near the inguinal region, two round bodies could be felt, which on pressure gave pain. The question was, were they ovaries or testicles. Professor Porro cut down on the right side, and found that the body was a testicle with epididymis and spermatic cord attached. The wound was closed up, the patient pronounced a man, and sent forth enchanted with his new status in society.

THE ORDER OF THE ROYAL RED CROSS.—The Queen of England has created a new decoration designated "The Royal Red Cross." It is to be bestowed as a recognition of special services in nursing or attending the sick and wounded soldiers and sailors. It seems to be intended chiefly for trained nurses.

THE MORTALITY IN THE CAPITALS OF EUROPE for the first quarter of the year 1883 is as follows: London, 22.1 per 1,000; Berlin, 24.3; St. Petersburg, 40.6; Brussels, 25.7; Paris, 27.3; Stockholm, 27.8; Vienna, 31.1; Madrid, 36.4.

Some comment might be made on the fact that in Vienna, one of the greatest medical centres of Europe, the mortality should be so excessive.

THE APPEARANCE OF THE PLAGUE IN KIL-DJIVARENO.—It is reported that the plague has appeared in Kil-Djivareno, a district of Persia, about twenty-five miles from the Turko-Persian frontier. It is not far from the district of Nonkris, where the plague appeared in 1878 and 1881.

MEDICAL BOARD OF EXAMINERS FOR ILLINOIS.—The Chicago Medical Society has appointed a committee to confer with the State Board of Health, as to the feasibility of a statute which shall invest the exclusive right to grant license to practise medicine in Illinois in a Board of Examiners, independent of all medical schools. The State Board of Health has submitted to the faculties of the various medical colleges a proposition that all individuals desirous of pursuing the study of medicine in Illinois shall be submitted to uniform preliminary examination by the State Board.

BRITISH MEDICAL ASSOCIATION.—The Fifty-first annual meeting of the British Medical Association will be held at Liverpool, England, on Tuesday, Wednesday, Thursday, and Friday, July 31, August 1, 2, 3, 1883.

A NEW METHOD OF DESTROYING THE FŒTUS IN CASES OF EXTRA-UTERINE PREGNANCY.—Dr. Kochmann, of Strasburg, reports a case of extra-uterine pregnancy, six months advanced, in which the fœtus was destroyed by a single application of sparks from a static battery. The duration of the sitting was about fifteen minutes, and sparks about one and one-half centimetres long were drawn.

Reviews and Notices.

THE PATHOLOGY AND TREATMENT OF DISEASES OF THE OVARIES. By LAWSON TAIT, F.R.C.S., Surgeon to the Birmingham Hospital for Women, etc. Fourth Edition. Re-written and greatly enlarged. New York : W. Wood & Co. 1883.

LAWSON TAIT's name is familiar to the profession as that of a leader in the department of surgical gynecology. His views are not always in accordance with those of many of his co-workers. Such as they are, however, they appear to follow logically enough from his personal experience, which is a large one. The present edition of his treatise on the ovaries differs in no essential respect from former ones, although the increasing number of his operations, and a constantly growing experience have necessitated an enlargement of the book. It forms an interesting and readable volume.

DIAGNOSIS OF OVARIAN CYSTS BY MEANS OF THE EXAMINATION OF THEIR CONTENTS. By HENRY J. GARIGUES, A.M., M.D., Obstetric Surgeon to the Maternity Hospital, etc. New York : W. Wood & Co. 1883.

THE present essay first appeared as an original contribution in the *American Journal of Obstetrics*, where it doubtless became familiar to a large part of the profession. It is now issued in book-form, without further changes or additions. The author presents a quite formidable array of conclusions, fifty-five all told, from which it appears that the importance of examining the fluid from cysts has been both under and over rated. The truth would seem to be, that while the examination of fluids affords no pathognomonic evidence, it is an important aid to diagnosis, and should not, therefore, be neglected.

THE DISEASES OF WOMEN : A MANUAL FOR STUDENTS AND PHYSICIANS. By HEINRICH FRITSCH, M.D., Professor of Gynecology at the University of Halle. With 159 Wood Engravings. New York : W. Wood & Co. 1883.

THE treatise of Professor Fritsch has achieved a rapid popularity in Germany. In its English dress it forms the March volume of Wood's Library. Its great merit lies in the conciseness of all statements, in its practicalness, and in the freedom from personal dogma. It is nevertheless essentially a German book, and can hardly aim to replace American and English text-books with us. In its special province, that of elucidating the present status of German advanced gynecology, it scarcely has a rival, at least not of equally small size. The American gynecologist will be pleased to discover that his German *confrères* are not behindhand in this much evolved branch of medicine.

AN INDEX OF THE PRACTICE OF MEDICINE. By WESLEY M. CARPENTER, M.D. Pp. 304. New York : William Wood & Co. 1883.

THE author's well-known literary skill, practical knowledge, and conservatism, led us to expect much of the present work. We have not been disappointed. It is an admirable epitome of practical medicine, giving in a most condensed form, yet carefully stated, nearly every point that the general practitioner would care to know about the diseases of the body. The arrangement of subjects is alphabetical, which allows of easy reference. The headings : "Synonyms," "Definition," "Etiology," "Symptoms," "Differential Diagnosis," "Treatment," are printed in thick, black letters, making the subdivisions prominent. Prescriptions are added in some cases, a feature which we can hardly commend.

The book is interleaved, so that the physician can add

his own therapeutical or symptomatological notes. It is a small octavo size, bound in sealskin, and wallet-shaped, so that it can be easily carried in the pocket and referred to as readily as the ordinary dose-books.

We believe that Dr. Carpenter's work will prove a boon to the general practitioner.

A MANUAL OF CHEMICAL ANALYSIS, as applied to the Examination of Medicinal Chemicals. By FREDERICK HOFFMANN, A.M., Ph.D., and FREDERICK B. POWER, Ph.D. Third Edition. Philadelphia : H. C. Lea's Son & Co. 1883.

THE third edition of this treatise takes due cognizance of general chemical progress, and more particularly of the advances recognized by the recent new issues of the United States and German pharmacopœias. As a reliable work of reference to those who require to be kept posted in matters pertaining to medical and forensic chemistry, the book has no superior. The general practitioner, however, need scarcely be burdened with a knowledge of its contents.

A MANUAL OF AUSCULTATION AND PERCUSSION ; EMBRACING THE PHYSICAL DIAGNOSIS OF DISEASES OF THE LUNGS AND HEART, AND OF THORACIC ANEURISM. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine in the Bellevue Hospital Medical College, etc. Third Edition. Revised. Philadelphia : H. C. Lea's Son & Co. 1883.

THIS well-known little treatise requires no notice, beyond mention of the fact that a third edition was called for a short time after the second had appeared. It appears, therefore, that its practical utility is duly appreciated, a circumstance which reflects credit upon the profession as well as the author.

THE MICROSCOPE AND ITS REVELATIONS. By W. B. CARPENTER, C.B., M.D., etc. Sixth Edition. With Plates and Engravings. Vols. I. and II. New York : W. Wood & Co. 1883.

THE well-known treatise of Dr. Carpenter has reached its sixth edition. The work has been issued in two volumes, forming the April and May numbers of Wood's Library of Standard Authors. It is hardly necessary to repeat what is so generally recognized to be true, viz., that this treatise constitutes the most complete and indispensable guide to the working microscopist published in the English language. The manual is not specially intended to be a medical book, but yet the physician will not fail to derive both profit and amusement from a perusal of its pages.

THE SYSTEMATIC TREATMENT OF NERVE-PROSTRATION AND HYSTERIA. By W. S. PLAYFAIR, M.D. Pp. 106.

THIS little work is a reprint of Dr. Playfair's previous communications on this subject. They show the favorable results obtained in England by the Weir-Mitchell method of treatment.

EXPERIMENTAL PHARMACOLOGY. A Hand-Book of Methods for Studying the Physiological Actions of Drugs. By L. HERMANN. Translated, with the Author's permission, with Notes and Additions, by ROBERT MEADE SMITH, M.D. 8vo, pp. 201. Philadelphia : Henry C. Lea's Son & Co. 1883.

THE increasing interest that American physicians are taking in experimental physiology and physiological therapeutics renders the present work a timely one.

The author describes the general method of pharmacological investigation, and claims for pharmacology the position of a distinct science, covering the subject of the action of drugs upon animals.

The special methods of studying the action of poisons upon the various organs and tissues of the body are then described. The book is a technical one for the assistance of those who wish to do actual work. Dr. Smith

has very numerous and valuable additions in the way of notes and comments. Many illustrations also are given. We trust that it will give a further impulse to the study of pharmacology in America.

FORMULAIRE DES MALADIES URINAIRES. Par F. MALLET. 8vo. pp. 292. Notes Therapeutiques et Cliniques recueillies à la Clinique, de la rue Christine, Paris. Adrien Delahaye et Émile Lecrosnier, Éditeurs. 1883.

THIS work covers the subject of the therapeutics of genito-urinary diseases, and it contains much that is useful. We especially commend the ingenious tables in the latter part, by which the various methods of treatment are presented in an admirably succinct manner.

STUDENT'S GUIDE TO DISEASES OF THE EYE. By EDWARD NETTLESHIP, F.R.C.S. Second American, from the Second Revised and Enlarged English Edition. With a Chapter on Examination for Color Perception, by William Thomson, M.D., Professor of Ophthalmology in the Jefferson Medical College. Philadelphia: Henry C. Lea's Son & Co. 1883.

THE verbosity of the chapter on "Examination for Color Perception," added by Dr. Thomson, is in strange contrast with the terse diction of the rest of this admirable Guide, which bids fair to become the favorite text-book on ophthalmic surgery with students and general practitioners. It bears throughout the imprint of sound judgment combined with vast experience. The illustrations are numerous and well chosen. From a reference on page 44 we infer that the English edition of the work contains test-types which have accidentally been omitted in the American edition.

On page 43 the statement is made that rays forming a visual angle of one minute "are very nearly parallel, and may be considered as coming from an object at an infinite distance." This is erroneous and apt to sadly confuse a tyro in physiological optics. On page 72 we read that by the direct method of ophthalmoscopic examination the parts are seen in their true position "unless the eye be myopic." This statement also needs correction. On pages 72 and 305 the dot is wanting in front of the figure 5.

These are the only blemishes we could detect on a cursory examination of this book, which, within the short compass of about four hundred pages, contains a lucid exposition of the modern aspect of ophthalmic science.

THE PRACTITIONER'S READY REFERENCE BOOK. By RICHARD J. DUNGLISON, A.M., M.D. Third Edition, thoroughly revised and enlarged. Philadelphia: P. Blakiston, Son & Co. 1883.

THE new edition contains numerous additions and illustrations, which the author believes will materially increase the value of the book. The volume now has five hundred and twenty-five pages, and medical topics as follows have been considered: Weights and measures occupy thirty-nine pages, which contain much useful as well as "handy" knowledge concerning weights and measures of the United States Pharmacopœia and of the metric system. Nearly twenty pages are next occupied with tables which give the solubility of medicines in water, alcohol, ether, glycerine, etc. The abbreviations in common use, the companion of thermometric scales, and the reference tables of size, weight, and specific gravity of different parts of the body are interesting and useful; perhaps not so much so to the general practitioner as to pathologists and specialists.

The Hippocratic oath that follows is good reading, especially in the light of the author's comments, who says that "*instead of displaying a narrow-minded and exclusive selfishness, it inculcates a generous line of conduct, and enjoins an observance of the rules of propriety*," etc. Simple, comprehensive, and, amid the present ethical agitation, interesting.

The pages which immediately follow possess the least

intrinsic value of any in the book. If all that appears concerning rules for the practitioner, rules of medical etiquette, and what the practitioner must learn of the patient, were totally expunged, it would greatly improve the work. So much of it is puerile and so much impracticable that what remains is like a plant that has grown in the shade; it wilts when it is brought to the sunlight.

The fifty pages which follow are devoted to doses of medicines for children and adults, administered by mouth, enemata, suppositories, etc. As a matter of course, the basis of much that these pages contain is the United States Pharmacopœia, but the simplification renders it very acceptable; so also is the material derived from other sources.

Hints as to prescribing.—How and what to prescribe is especially interesting when read in conjunction with the selected prescriptions found a few pages subsequently. Probably the eight pages of incompatibles will be as little observed in practical prescribing as anything that appears in the book, and as evidence that such may be the case, the reader has only to refer to the prescriptions selected by the author himself—and selected because they have been employed with good results by eminent authorities—where can be found incompatibles in combination *in abundance*. A fair sample is the following: Hæmatoxylon has among its incompatibles mineral acids and opium, and one prescription reads as follows: R. Acidi sulphurici aromatici, ext. hæmatoxyli, tinct. opii camphorata, and syrupi zingiberis.

The selections included under the head of "Hygienic and Therapeutic Management of Children" are very good. They are from such men as Goodell, Albert H. Smith, Meigs, and Pepper, of Philadelphia, A. A. Smith, of New York, Eustace Smith, of London, and others, whose opinions are entitled to favorable consideration.

Several pages are occupied by tables of differential diagnosis, credited to Etheridge, of Chicago, Roberts ("Theory and Practice of Medicine"), Seiler ("Diseases of the Throat"), H. Augustus Wilson, of Philadelphia ("Fractures and Dislocations of the Femur at the Hip-joint"), and Bramwell, of London ("Cardiac Valvular Murmurs"). These are only fairly good. Roberts' is the best. A few words would have made each much more complete than it is. For example, all the symptoms enumerated as *characteristic* of typhoid, with a single exception, may be present in other affections, and the real peculiarity of the single symptom is not pointed out.

The tables on "Fractures and Dislocations of the Femur at the Hip-joint" are lamentably deficient. They were evidently abstracted from one author. The amount of shortening given varies so much from that laid down by the authority generally accepted in the courts, that they are not entitled to consideration. They have been made up without reference to either the influence of impaction or the situation of the fracture in the neck. No mention has been made of Bryant's line, accepted as one of the most reliable guides in obtaining the amount of shortening. Nor has attention been directed to the fact that measurements from the anterior superior spinous process of the ilium to the malleolus at the ankle have been largely discarded because it has been definitely ascertained that there is, in most persons, a difference in the length of uninjured lower extremities. As it now stands, the author would do well to either revise this table or substitute another.

The rules for chemical examination of the urine were arranged and condensed from J. Hughes Bennett's "Text-book of Physiology," published in 1873. These also need revision, and we are surprised that the author, with his well known habits of precision, should have allowed them to remain without certain modifications. For example, it is established that certain articles of diet so affect the urine that a precipitate like that yielded by sugar will be formed on the application of Trommer's test. Fehling's

solution, when fresh and properly applied, undoubtedly gives the most certain results, although the rules leave it to be inferred that it is otherwise. In the present state of our knowledge it is very questionable whether the terms fibrinous, hyaline, waxy, should be used to define different varieties of casts. Sometimes casts can be obtained much more certainly from the urine *along the sides of the glass*, or in the cloud which forms part of the way down, than from the sediment at the "bottom of a conical glass."

Under the head of "Treatment of Poisoning" we find no reference to electricity, certainly a most valuable agent, although mention is made of various other external measures. This leads us to speak, in this place, of the chapter "On the Use of the Galvanic Battery," condensed from a discourse by H. Tibbits, M.D., of London, 1877. The writer uses the term "electrization," and says that the remarks concerning it apply *equally* to Voltaism (galvanism) and Faradism. We do not believe that this view is sustained by the best authorities of the present day. "Electrolysis has been successfully employed in several cases of *aneurism*." True; but our best surgeons would hesitate for a long time, probably reject it *in toto*, before adopting the measure in aneurism of the arch of the aorta, as suggested here.

"How to Apply Trusses," "How to Use the Clinical Thermometer," "How to Apply Bandages," "How to Apply Immediate Relief in Recent Accidents or Sudden Illness," "Suggestions for Nursing of the Sick," "Dietetic Preparations and Precepts," and "How to Conduct a Post-mortem Examination," are the titles of the more important chapters which follow. These pages contain a goodly proportion of acceptable items. The section on "Stained Sections of Animal Tissues and How to Prepare Them" might be simplified to advantage for a book of this kind, prepared, as it has been, for the general practitioner.

The reputation already acquired by the author for care and painstaking in detailed work has been maintained in this edition of his book, and with slight revisions in certain parts, some of which have been suggested, this volume will form a substantial addition to the many books of ready reference now in the hands of the profession.

A TEXT-BOOK OF THE DISEASES OF THE EAR AND ADJACENT ORGANS. By DR. ADAM POLITZER. Translated from the German by James Patterson Cassells, M.D., M.R.C.S., England. With two hundred and fifty-seven illustrations. Pp. 800. Philadelphia: Henry C. Lea's Son & Co. 1883.

DR. POLITZER has been long known as a profuse contributor to the literature of otology, and through English translations in the medical journals of the past fifteen years most of his views have been made known. The large volume before us is presumably a collection of the author's views in the various departments of the subject, and will therefore find a place in the library of every one who wishes to keep informed in the literature of otology.

The author divides the organ of hearing, for the purpose of discussion, into two principal parts, the *sound-conducting* and the *sound-perceiving* portions, which he regards as the only correct one from the pathological standpoint. In the former are included—*a*, the external ear (auricle and external meatus); and *b*, the middle-ear (the tympanic cavity with membrano-tympani and ossicula, Eustachian tube, and mastoid process). The latter, the so-called internal ear, is divided into: *a*, the origin of the auditory nerve in the brain; *b*, the trunk of the auditory nerve, and *c*, its expansion in the labyrinth. After this division of the organ of hearing the author passes on to the special description of the anatomico-physiological relations of the human ear. There are 73 pages devoted to this subject. To the diseases of the conducting apparatus, general and special, there are given 110 pages. The diseases of the middle ear, consisting of affections of the membrana tympani, of the tympanic cavity, of the

naso-pharynx, of the adhesive and purulent inflammations of the middle ear, and diseases of the mastoid process and external ear, occupy 393 pages, while 85 pages are given to ear disease and life assurance. The anatomy and physiology of the internal ear, special and general diseases of the labyrinth and auditory nerve, injuries of the internal ear, cerebral disturbances of hearing, malformations of the ear, deaf-mutism, hearing instruments for the deaf, and appendix of therapeutical formulæ, occupy 101 pages of the book.

While this work evinces a great amount of labor, including not only the author's own observations but also an extensive compilation of the researches of others in this special department of medicine, yet its chief value is, as a work of reference, for the specialist. The author could have, perhaps, given the work more value had he possessed more decided convictions concerning certain matters discussed. For example: a perusal of the whole subject of the subjective symptoms of diseases of the ear is confusing, and leaves the reader without a clear idea of the subject. Thus he says, page 192: "Subjective noises in the ear, which are always caused by some irritation of the auditory nerve, arise either from disease of the ear itself or *by reflex transmission from the cerebral and spinal nerves to the auditory nerve*." The portion of the above sentence which we have italicised is an example of dogmatism without evident meaning, which occurs rather frequently in the work before us.

When the American practitioner comes to consult this book for guidance in the treatment of aural disease he will most likely be somewhat disappointed, unless he be familiar with the German methods of medication which are considered here—we may be permitted to say, as somewhat excessive as regards local medication, notably in skin affections. Let us here examine what Dr. Politzer has to say concerning the treatment of acute inflammation of the middle ear. He says, on page 253—"The treatment of acute inflammation of the middle ear in the beginning of the disease, and as long as the congestion and the active symptoms last, is palliative. The main duty of the practitioner at this time consists in the removal or alleviation of pain, and only in the subsequent course of the disease does the indication for treatment of the pathological process and of the functional disturbance appear." In the more intense degrees of inflammation, it is true, local blood-letting is recommended, but the only internal treatment suggested is the administration at night, if the pain disturbs sleep, of small doses of acetate of morphia, or if that does not agree well with the patient, the chloral hydrate in solution. To assist perspiration in certain cases he employs a cup of tea, or a decoction of lime blossoms, the action of which is increased by adding a spoonful of spirit. mindereri.

The author's general treatment of acute purulent inflammation of the middle ear does not differ materially from the above. Now, in the acute stage of these diseases, we may in many instances do much to prevent their progress, and the literature of the day is suggestive of further advances even in this direction. The employment of calcium sulphide, and some of the mercurial preparations have been used here with marked benefit, according to reliable authorities. Then the practice here, as regards local treatment, has undergone a great change. The employment of solutions are much less resorted to than formerly, and the dry treatment has now many advocates. Politzer recommends only solutions in this affection.

Otologists are indebted to this author for a valuable and simple means of inflating the tympanic cavity, which method, as is well known, bears the author's name. That inflation of the ears is greatly abused is not the fault of the author, although one might almost wish, on witnessing the unnecessary, nay, frequently injurious employment of the air-douche, that it had never been invented. On the whole, this is a valuable contribution to otological literature, although not well adapted to the use

of the general practitioner. We cannot but express regret that the publishers had not, instead, given us a new edition of their own Treatise on the Ear, inasmuch as the author, Dr. Burnett, is well known to entertain advanced views in the treatment of aural diseases, and hence would be able to bring his work up to the demands of the present day.

The book under review is well printed, on excellent paper, and, although bearing the imprint of an American house, is evidently of English manufacture. The numerous illustrations are in the main very good, and some of them quite new. The representations of the drum-head in various pathological conditions are notably suggestive. The translator, Dr. James Patterson Cassells, of Glasgow, deserves the thanks of all who rely upon a translation from the German into English for access to Dr. Politzer's views, and he seems to have merited the approval bestowed upon this work by the author. It may be remarked in conclusion, that the work before us is not well bound, the sheets being too heavy for the muslin covers.

ON THE PATHOLOGY OF BRONCHITIS, CATARRHAL PNEUMONIA, TUBERCLE, AND ALLIED LESIONS OF THE HUMAN LUNG. By D. J. HAMILTON, M.B., F.R.C.S.E., F.R.S.E., Professor of Pathological Anatomy (Sir Erasmus Wilson Chair) University of Aberdeen. With Illustrations. London: Macmillan & Co. 1883.

THIS work will be read chiefly by pathologists. It is made up of a series of papers which were published in *The Practitioner* in 1879 and 1880. Part I. is devoted to bronchitis, and, pursuing a well-established method of teaching, the author directs attention, first, to the structure of the normal bronchi. His views concerning the morbid changes in this affection are based upon the anatomy of the parts as he has seen it under the microscope. He recognizes three varieties of cells in the epithelial layer: 1, the columnar epithelial cells (ciliated); 2, the deep germinal layer (Debove's membrane); and 3, the perfectly flat layer lying upon the homogeneous basement membrane. Besides, the author describes other cells, which are regarded as of transitional shape (beaker cells of older writers), and he traces what, to him, seems to be a direct line of ascent from the endothelial layer through the germinal layer to the fully formed columnar (ciliated) epithelial cells.

The author also directs especial attention to the basement membrane, quite hyaline, only a few granules here and there interrupting the invariably homogeneous translucency, and this basement membrane of the mucosa, as he calls it, is said to play an important part in the pathological process of acute bronchitis. There have always been (since instruments of precision were first invented) differences of opinion concerning the minute anatomy of various parts of the human body, and equally divergent opinions still exist, notwithstanding the improvement and apparent perfection in the means for observation. Probably such differences will continue to exist, and in the very nature of things must be tolerated; but they are entitled to consideration when they give evidence of careful investigation. So it is with the views promulgated by this author—they are entitled to consideration.

The first change in the process of acute bronchitis, says the author, occurs in the branches of the bronchial artery ramifying in the inner fibrous coat immediately beneath the basement membrane of the mucosa. These become engorged, and within from twenty to thirty hours desquamation of the columnar epithelium, with some of the transitional forms of epithelium, takes place at the foci of greatest congestion. The basement membrane, in the meantime, becomes swollen and redematous, and it is this condition that facilitates the shedding of the epithelium.

This theory is excellent, and the author sustains it with illustrations made from actual specimens. The faithfulness of the cuts we do not question, but it occurs to the

reviewer to suggest that the theory would be stronger had the author demonstrated that the circulation in the terminals of the bronchial arteries is the *only* vascular supply which the mucosa receives, and in the event of blood supply from another source, that the condition of the bronchial artery is the *only* one disturbed. For eminent histologists have demonstrated, as they believe beyond question, that the blood supply for the bronchial mucous membrane is not derived *solely* from the bronchial arteries. In the first part the author also studies the varieties of chronic bronchitis, chronic interstitial pneumonia, vesicular emphysema, bronchiectasis, and catarrhal pneumonia as complications of bronchitis.

Part II. contains a dissertation on catarrhal pneumonia and tubercle in the human lung. The term "catarrhal" as applied to pneumonia is retained, although the author says in one place, "catarrhal so-called," thus partially indicating that another word would be more correct, and, therefore, more acceptable. In speaking of the microscopic appearance of tubercles, he lays great stress on the presence of giant cells, and goes further in this direction than almost any other observer. For example, he says that "in tubercle of the lung and of all other organs they (giant cells) are invariably present whenever the nodule becomes defined." This may be true for the University of Aberdeen, but the statement does not hold for the United States.

The general style of the writer is pleasing, and from the manner in which the subjects in this book have been treated it is evident that the author is familiar with the practical manipulations necessary to their proper study from a pathological standpoint. A slight tendency, however, manifests itself to make statements and leave them unsupported. This, in a work of this kind, should not occur, as the evident intent of the author is to be quite exhaustive with reference to the morbid changes that take place in the diseases under consideration. The illustrations are very good; at all events they possess one characteristic which is acceptable, and that is they do not seem to be largely the work of imagination. The last article is "On the Supposed Contagiosity [a word deficient in euphony, at least] of Tuberculosis and Pulmonary Phthisis." It contains an account of Koch's discovery, a description of the methods by which the bacillus has been demonstrated, and is a brief *résumé* of what was known on the subject at the time the book was published. As a whole the book is worthy of a place upon the shelves of those who are interested in the pathology of these diseases.

DEEP BREATHING AS A MEANS OF PROMOTING THE ART OF SONG, AND OF CURING WEAKNESSES AND AFFECTIONS OF THE THROAT AND LUNGS, ESPECIALLY CONSUMPTION. By SOPHIA, MARQUISE A. CICCOLINA. Illustrated. Translated from the German by EDGAR S. WERNER. New York: M. L. Holbrook & Co. 1883.

THE authoress advocates, enthusiastically, the systematic cultivation of voluntary abdominal breathing. She considers it an indispensable help to the art of correct singing, and a hygienic measure of great value in asthma, consumption, and weak lungs. We have heard that the practice of teaching young women abdominal breathing for the production of the voice is not entirely devoid of danger.

TREATING DYSPEPSIA WITH SAND.—Dr. G. Kerlus argues from the facts of comparative physiology that fine sand is a good thing for dyspeptics to take with their food. Herbivorous animals all eat a little dirt with their regular food, and it makes it more "porous." Fowls and birds of all kinds also take sand with their meals. Why not, therefore, man, says Dr. Kerlus. Putting this brilliant piece of inductive reasoning into practice, he has administered finely ground sand with the food of his patients, and, of course, reports cures.

SECTION IN OBSTETRICS.

Stated Meeting, May 24, 1883.

ALEXANDER S. HUNTER, M.D., CHAIRMAN.

DR. PAUL F. MUNDÉ read a paper (see page 673) on

THE TREATMENT AND CURABILITY OF CHRONIC UTERINE CATARRH.

DR. W. GILL WYLIE said that he agreed with the author of the paper in many respects, while he differed with him upon several other points. In the first place, he had not met in his practice with quite so many cases such as had been described by Dr. Mundé and others as incurable. There are cases of endocervicitis which undoubtedly are incurable unless we destroy the mucous membrane, but he did not think they were so common as had been supposed, and the same could be said of endometritis.

Although the subject of etiology did not enter into the paper, there was one point to which he would direct attention, namely, he believed that many of the so-called cases of incurable uterine catarrh were due to the general condition of the system, or to a diathesis, and that although the catarrh might be improved temporarily, if the diathesis was permitted to remain uncorrected the local condition will return. Dr. Wylie also believed that uterine catarrh was more frequently due to disease of the Fallopian tubes than had heretofore been considered. He had lately had two cases of this character under observation. In one the patient had been treated for several years, but still there was a purulent discharge in the vagina, especially when the patient was upon her back. After treating her for a little time by the use of the glycerine and alum tampon, which not only by pressure but by producing an alterative change, affected the parts, he was able to readily diagnose this condition of the tubes, and after they had been removed he could press exactly the same kind of discharge from the tube which he had always found in the vagina. He had seen other cases in which the discharge was mechanical in character, and came from the tubes.

His method of treatment for uterine catarrh was not so heroic as that which had been described by Dr. Mundé. If a patient came to him with cervicitis, with the slightest tenderness, he commenced with simple applications of pure glycerine upon cotton, not oftener than once in three days. He followed this for a time with a saturated solution of alum in glycerine, to which had been added a very small quantity of carbolic acid, making the applications once in three or four days. Then for the first time he passed a sound, and, as a rule, especially if the patient has not borne children, it will be found necessary to dilate the cervical canal. For that purpose he employs Sims' instrument, dilating first the external and then the internal os to some extent, and then begins the treatment of whichever cavity is diseased. If the mucous membrane of the cervix is extensively diseased, after trying astringents, although they did not do much good, he generally uses the curette, particularly if the patient complains of menorrhagia. After using Sims' curette thoroughly he then makes an application of pure carbolic acid, and rarely uses anything more powerful than this. He does not like to use nitric acid because of the possible contraction of the eschar. He was very certain that the cervix did contract after the use of the actual cautery. One reason why a cure is not effected was that the curette and the local applications were too frequently not thoroughly done. The same remarks applied when the lesion was higher up. Applications to the uterine cavity without dilating to some extent the internal os, were of no use whatever. The application should be made through the curved silver tube, so that it can be

delicately touched to every point, and if so done, seeing that each little delicate recess was touched with the local application, many of these cases can be cured which have heretofore been regarded as incurable. He did not believe that there were many cases in which nitric acid was necessary above the os internum. As a rule, in his hands carbolic acid accomplished all that could be desired. If the uterus is soft and large he uses iodine. If the uterus is indurated and hard, being in the position of anteversion, and the patient complains of trouble about the bladder, etc., having been about town under treatment for years, he had found that these cases were about the easiest ones which he had to treat, because they had been almost universally treated without enlarging the internal os. But in these cases, even with the uterus enlarged and the cervical canal open, he always prepared the parts by removing tenderness with the applications of glycerine and alum, and if the cervix was not open, subsequently dilating it with the Sims dilator, observing throughout the strictest rules of cleanliness, wetting the instrument with some antiseptic, as carbolic acid or iodine. Frequently these cases will be relieved within a week, and can be cured within six weeks by adopting this plan of treatment. He really thought that it was the method of applying the treatment rather than any special treatment of itself, as it was in many other cases, which makes it successful. He also thought that if the general condition of the patient was neglected, probably the local condition would return, and of all the diatheses which might give rise to it he thought that the rheumatic was the most active.

DR. L. WEBER said that he was glad to hear that Dr. Mundé regarded his cases as cured, for the time being at least. The treatment which he had adopted for several years was that practised by Amann, of Munich. After dilating the internal os with the tupelo tent, with the thorough application of the curette, Sims' in preference, he had followed the plans of Professor Amann in using mitigated nitrate of silver, making a thorough application to the mucous surface. This he had usually done with the ordinary Lallemand's porte-caustique. He had not seen any disagreeable results from this method of treatment. He had known of two deaths following the use of nitric and chromic acid. Whether he had absolutely cured these cases he was unable to say positively, but he knew that they had received a great deal of benefit from the treatment which he had adopted.

Dr. Weber also believed that there was an undoubted connection between these intractable catarrhs and the general condition of the patient. He should prefer to lay stress upon the intimate connection between this local condition and the scrofulous or tuberculous diathesis rather than gout or rheumatism. Again, in at least half the cases he had seen, such as the general practitioner very often encounters, the disease had followed early abortions. He related one such case, in which acute tuberculosis developed after miscarriage, and the patient died within two years.

DR. TAUSZKY said he had found mild applications the best to be resorted to at first. He had not used nitric acid, but had for the most part followed the rule which the late Dr. Peaslee recommended, namely, commence with mild applications, and then gradually reach the strongest solutions. In most cases there was some form of displacement present which, of course, should first be corrected. For many years he had used cotton tampons after using glycerine in the preparatory treatment. If he failed with mild applications he then resorted to stronger ones.

THE CHAIRMAN said he had never used nitric acid within the uterine cavity or the cervical canal. It occurred to him that we should consider the existing cellulitis, if any were present, and adopt measures to remove it entirely before proceeding further, and then consider the condition of the uterus. If subinvolution is present he had been accustomed to resort to hot water injections, the local application of glycerine, and was fond

of applying a sponge-tent without curetting. The spongetents he had made with the utmost care, prepared antiseptically, and just before their introduction the surface was wet and covered with soap, and then rolled in finely powdered salicylic acid. After introducing the tent it was allowed to remain forty-eight hours, the patient in the meantime being confined absolutely in bed, the bowels having previously been moved freely so that it was not necessary during the forty-eight hours to rise for this purpose. In many cases, after the tent had been thus applied and removed, the catarrhal discharge had ceased entirely, and with it the condition of subinvolution had disappeared. In the event of failure he then resorted to more active measures. In those cases in which the uterus is anteverted he used tents, and after removing thoroughly with the curette the degenerated mucous membrane of the uterine cavity, thoroughly wiped away all the blood, and removed every particle of secretion, he applied the strongest solution of carbolic acid; and he had been entirely satisfied with the results.

DR. MUNDÉ, in closing the discussion, remarked that undoubtedly the scrofulous diathesis had a great deal to do with the production, or at least the continuance, of the disease under consideration. He was particularly pleased with Dr. Weber's statement concerning one point in the etiology of the affection, namely, that in the large proportion of the cases it followed early abortion, by which he supposed Dr. Weber meant subinvolution, which usually accompanies these cases. That had also been his experience, but, as had been remarked, the etiology of the disease had not entered into the scope of his paper. His principal object was to point out that many of these cases, which had been intractable to treatment, did not improve under *mild* applications, no matter how conducted, but would, in a certain proportion, get well under *heroic, active, and persevering* treatment; at least get cured sufficiently long to get rid of their sterility; and if that was the prominent feature in the case the great object of treatment was accomplished. Besides, many of them were cured of the uterine catarrh. Dr. Wylie had laid stress on the preparatory treatment. This was perfectly correct. Dr. Mundé did not speak of preparatory treatment to any very great length, because it was his special point to discuss active treatment for the cure of the disease. Preparatory treatment is quite as important, and in cases where the uterus is immovable it may be one of the essentials; but where the uterus is perfectly movable, it may be as well, perhaps, to go on with the heroic treatment at once.

For the class of cases to which Dr. Wylie had referred, Dr. Mundé would not touch one of them with the curette or with nitric acid. If there existed cellulitis of the remotest origin he would not apply either the curette or nitric acid until, at least, he had tried all other methods without success. With regard to the objection to the use of nitric acid because it was liable to be followed by contraction of the cervical canal, Dr. Mundé admitted that this contraction does take place, but he did not care for this because in these cases the canal is, as a rule, already too large, and a moderate amount of contraction is desirable. But it should be recollected that he did not recommend the application of the nitric acid sufficient to make a deep slough. With regard to carbolic acid having been sufficient, he could only say that he had occasionally succeeded in the use of this remedy, but he had more frequently failed. He had not used either the actual cautery or the galvano-cautery. He thought that Dr. Hunter's use of salicylic acid was an excellent one, but suggested that the results possibly might be due to the effect of the acid quite as much as to the effect produced by the sponge-tent.

One important point he had neglected to mention in his paper, and which it might have been well to have incorporated, namely, the contra-indications to the use of any of these strong applications to the cervical and uterine cavity.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 28, 1883.

DAVID WEBSTER, M.D., PRESIDENT, IN THE CHAIR.

THE USE OF ANTISEPTICS AFTER ABORTIONS AND LABOR.

DR. W. GILL WYLIE read a paper on the above subject, in which he stated that in 1870 and 1871, while an interne in Bellevue Hospital, he saw much of septicæmia in surgical cases and something of the same in puerperal cases. Under the teachings of the late Prof. James R. Wood he became a believer in carbolic acid, and by its free use subsequently, while serving in the lying-in wards, he delivered thirty-six women without the occurrence of a case of puerperal fever, and he believed that this result was due to the free use of carbolic acid, and the burning of all sponges, rubber cloths, etc. All these women had some rise of temperature, but none over 102° F. at any time. In 1872 Dr. Wylie saw Dr. Lister at work in his wards in the infirmary at Edinburgh, and became a convert to his antiseptic methods, and had since in private practice adopted the antiseptic plan, especially following the practices and teachings of Lister in all cases of labor. Nearly without exception the temperature after confinement in his practice had not risen above 100° F. There had not been even a so-called milk fever, and the well-known odor of the lying-in woman had been absent. The method is as follows:

First.—Examine locally every case some weeks before labor; have a trained nurse several days before confinement is expected; if lochia are present, warm vaginal douches of carbolic solution, 1 to 40, are given twice a day, and in all cases, as soon as the first symptoms of labor begin the vagina and vulva are thoroughly washed with the same solution.

Second.—Remove all useless and old stuffed furniture from the room; disinfect with the spray of carbolic acid everything that remains in the room; see that a large supply of napkins and bed linen are on hand, all of which are carbolized with the spray immediately before being used; change the linen every day; also have two sets of blankets; air them and use them alternately; wash the hands and all instruments in a solution of carbolic acid, 1 to 20.

Third.—When labor begins commence the production of the carbolic spray, and after labor every napkin is carbolized, or carbolized muslin or oakum is used to catch the lochia, and changed according to the discharge every hour or two, night and day.

Fourth.—Immediately after labor wash the external parts thoroughly with the 1 to 30 solution of carbolic acid, and give vaginal douches from two to four times a day. This is kept up faithfully for six or ten days, as may be required.

Fifth.—The test for the thoroughness of this method is that at no time should one be able to recognize by the smell the odor such as usually characterizes the lying-in woman.

For cases of abortion endeavor to carry out the same line of practice. Dr. Wylie then read the history of several cases.

He had reached the conclusion that it was best to consider the uterus after an abortion precisely as surgeons of to-day regard a punctured wound, and just as likely to be poisoned and beset with dangers when neglected or badly treated. He proceeded, therefore, upon the following plan: First, that septic matter must be excluded with great care, and that antiseptics are of great service in preventing infection; second, that perfect drainage is just as essential as in a severe contused and punctured wound; that not only versions, and especially flexions, may cause retention of lochia, but contraction and swelling of the os internum very frequently is an active cause in preventing a constant and free discharge; third, that when septicæmia has begun within a reasonable time, say

within ten or twelve hours after the first chill or high temperature, in almost all cases the patient may be saved by perfecting the drainage and by washing out the cavity either of the vagina or the uterus, as the case may be, by frequent douches of a solution of carbolic acid of a strength of from 1 to 40 to 1 to 20; fourth, that medication, except so far as it keeps up the strength of the patient, has little or no direct effect, and that the washing out with the carbolic acid not only removes or renders inert the organisms on the surface of the wound or cavity, but in all probability sufficient carbolic acid is absorbed locally into the surrounding tissues to weaken if not to stop the active reproduction of the organisms or the generation of poison associated with them.

He was fully aware that many cases very soon reached a stage where neither local nor any other treatment could arrest the disease, such as those where the poison has extended rapidly into the connective tissue, or has been carried a distance from the surface by the lymphatics or the veins, and started a new centre of local poisoning. But he believed that most of these hopeless cases began as simple ones, and if treated in time would never reach such a dangerous stage.

He did not advise intra-uterine injections in all cases. If the disease is confined to the vagina, apply antiseptics to that canal, but do it often enough to keep up their influence for at least twelve consecutive hours. Usually, if puerperal fever has lasted for several days, or if the symptoms are dangerous, it would be better not to delay washing out both the uterus and vagina, and do it vigorously and faithfully, and do not be satisfied with the uterine injection twice or three times a day, or even every three hours. He favored intermittent irrigation instead of continuous irrigation, for the following reasons: First, it is more readily and with greater safety carried out; second, it gives the parts, if not the patient, a little rest; third, douching at short intervals, we can use stronger solutions with less risk of poisoning with the antiseptic than when the continuous stream is employed.

What should guide us in the use of antiseptics after abortion? The first symptom is usually a chill, or chilly sensation, arrest of the lochia, and then a rapid rise of temperature. If in such a case an extensive laceration of the perineum, or cervix, or wound of the vagina were found, he would wash out the vagina with a solution of carbolic acid, 1 to 20 at first; after this give douches regularly, every fifteen minutes or half an hour, for three or four hours, of a solution 1 to 40. If the temperature then fell gradually, he would continue the douches in the same manner every twelve hours or more; but if, notwithstanding these vaginal douches, the temperature should continue to rise, or go up rapidly after lessening for several hours, he would at once begin intra-uterine douches, giving one of 1 to 20; and after this douches every half hour of 1 to 40, until the temperature fell to normal.

When the injection returns clear and remains so for several injections, almost invariably the temperature is found normal.

It is especially important, in giving the intra-uterine douche, to be certain that the carbolic acid is pure, and he insists upon having Calvert's No. 1.

The histories of several cases were given which he had seen in consultation. Dr. Wylie also referred to the histories of nine cases which he had treated successfully in Bellevue Hospital.

His experience with the dangers of intra-uterine injections was limited. In one case shock was produced, and it was afterward found that the solution had entered the peritoneal cavity through the Fallopian tube. The patient, however, recovered. In some cases shock was produced without any apparent explanation. If a large tube, such as Chamberlain's, is used after the os internum is well contracted, the instrument may be hugged so closely that the uterine cavity will be filled with the fluid injected. Under these and similar circumstances, of

course, the solution might be forced through the Fallopian tube into the peritoneal cavity, or a clot might be forced through a vein or sinus and do harm. But if a gum-elastic catheter was used of sufficiently small size to pass very readily, with a thread tied around it two and a half inches from the fenestrated extremity, indicating the distance to which it should be introduced into the uterus, not only would the fluid escape, but very frequently large threads of debris, clots, etc., would be brought away.

In those cases where the uterus was flexed, or the os firmly contracted, and where there is imperfect drainage, the tube can be left in the uterus, cut off close to the vulva, and a piece of soft rubber tubing attached when the injection is given. When left in this way it served as a drainage-tube, and the lochia should be caught by a carbolyzed napkin or dressing at the vulva.

One special object which the author had in reading the paper was to advocate the frequent and long-continued use of antiseptic dressings, when once begun, in cases of puerperal septicæmia, and to make it plain that three or four vaginal or intra-uterine injections given in twenty-four hours is not sufficient to do much good, and was likely to result in the disuse of the best, and in many cases the only, means of preventing death from septicæmia; that vaginal and intra-uterine injections of carbolic acid of a strength of from 1 to 40 to 1 to 20, will save almost all cases when begun early, and that it will often save apparently hopeless cases.

DR. MUNDÉ said that he had attained very positive convictions upon the subject of Dr. Wylie's paper, and that he had employed, with very satisfactory results, the use of antiseptics after abortions and labor. He had thought, however, where there was no offensive discharge from the uterine cavity or vagina, that intra-uterine injections were not useful. Since the introduction of Dr. Chamberlain's tube, however, he had, in every case in which the vaginal temperature reached 102° F., used the intra-uterine injections, and had generally found it sufficient to use them three or four times a day. He was very firmly convinced where there is a rise of temperature due to septic endometritis, where there are decomposing substances within the uterus, giving rise to that condition commonly known as puerperal septicæmia, that intra-uterine injection, repeated as often as the temperature may rise, and continued until the temperature comes down and remains, is perhaps the only proper local treatment to be employed. But the time arrived when such injections could no longer be of use. He had used them in cases where the temperature went up and down, and finally discovered that the rise took place very soon after the injection had been given, and the patient also complained of some pain. He had thought that in such cases the injections did not do any more good, but, on the contrary, developed a traumatic influence which was kept up, and which had better be avoided. He believed, if the temperature was substantially unaffected after using the injections for twenty-four or forty-eight hours, that they would no longer do any good, and in those cases he had given ten grains of salicylate of soda every two hours, which had produced lasting reduction of temperature, even after quinine, administered in large doses, had failed. He thought there was a certain danger in the use of intra-uterine injections, a certain amount of risk of washing away too much of the accumulation in the uterine cavity, and there was also a possibility of laying open some sinuses. He did not favor continuous irrigation of the uterine cavity. If there is no offensive discharge he did not see the utility of washing out the uterus. However, it might do some good, but he thought salicylic acid or quinine, to prevent rise of the temperature in these cases, would be better than injections.

DR. MALCOLM McLEAN had seen two cases in which air had been introduced into the cavity of the uterus with almost fatal consequences while intra-uterine injections were given. At the same time, notwithstanding

this objection, he regarded the recommendations in the paper as most excellent, and worthy of being commended. He believed that the temperature, which in many instances was the active agent in destroying the patient, could be reduced by this plan. He objected to leaving the catheter in the uterus during the intervals while the injection is not being made. He thought it a dangerous precedent to establish, because it was almost impossible not to have some air in the tube which might subsequently be driven into the uterine cavity. In cases of abortion he thought that swabbing the uterine cavity with a strong solution of carbolic acid answered a most excellent purpose. There is sufficient room for this, but scarcely enough, in many cases, to carry out the plan of irrigating the uterus by means of a tube. There were certain old cases of septicæmia, to which Dr. Mundé had referred, which had not seemed to be benefited by the intra-uterine injection. He thought it well in all such cases to be sure, if called in consultation, to find out as to whether the uterine cavity had been injected thoroughly. It may be reported that it has been irrigated thoroughly, whereas it may not have been irrigated at all, but the injection has been simply vaginal. He believed that the soft, flexible catheter was about as good an instrument as any which can be used in giving intra-uterine injections, and he thought it a good plan to keep one finger in close contact with the cervix, to determine whether or not the return flow from the uterus was actually taking place.

DR. H. J. GARRIGUES thought that we should distinguish between prophylactic and curative measures. He had been favorably impressed with the antiseptic plan as a prophylactic measure, but less favorably impressed with it as a curative measure in private practice. In hospital practice he had not obtained the results which he had expected from it as a prophylactic measure, notwithstanding very thorough antiseptic precautions had been observed. As a curative measure, however, in hospital practice, it had seemed to him to be very valuable, especially the intra-uterine injections. These injections, according to his experience in the New York Maternity Hospital, had invariably brought the temperature down, and they had been repeated as soon as it rose again, and to the best of his recollection they had not been required oftener than once in three hours. He had also used a concentrated solution of boracic acid and a solution of iodine with excellent results in the cases in which he wished to avoid the depressing effects of carbolic acid. In gangrenous cases he had used a ten per cent. solution of camphor, and also iodoform with very satisfactory results. In diphtheritic cases he had employed an eight per cent. solution of chloride of zinc, besides the intra-uterine injections of carbolyzed water, repeated once a day for seven or eight days, with excellent results. At the same time, if the parts affected with the diphtheritic exudation could be seen, a solution of chloride of zinc, 1 to 1, might be applied locally, and repeated if necessary. He agreed entirely with the author of the paper, that intra-uterine antiseptic injections were of the greatest value after abortion and labor. He preferred to use the gum-elastic catheter in their administration. He did not think that the entrance of air did much harm, for it would be immediately carried out of the uterus by the injection.

DR. WYLIE, in closing the discussion, said that most of the points referred to by those who had participated in the discussion, and the objections mentioned, had been considered and answered in the histories of cases, which he did not read on account of lack of time. He had not seen any trouble from the entrance of air into the uterine cavity. He usually employed the gum-elastic catheter No. 12.

With regard to waiting for the offensive discharge, he thought that that was just the point where fatal mistakes were made, for the reason that the uterus might become poisoned in consequence of imperfect drainage without the appearance of any offensive vaginal discharge. He believed that the severe cases were those which had been

neglected too long, or those in which perhaps one injection had been given and not repeated until after the lapse of six or eight hours. With regard to swabbing the uterine cavity, he thought it doubtful, in very many cases at least, that every little recess among the tissues could be thoroughly reached by this method. He was unable to understand why poisoned wounds of the uterus should be considered and treated differently from any other poisoned wounds.

The Society then adjourned, to meet on the fourth Monday in September.

STATE MEDICAL SOCIETY OF ARKANSAS.

Eighth Annual Meeting, held at Little Rock, May 30 and 31, 1883.

(Special Report for THE MEDICAL RECORD.)

THE State Medical Society of Arkansas convened at 11 A.M. Wednesday, in the hall of the House of Representatives, and was called to order by DR. CLAIBOURNE WATKINS, Chairman of the Committee on Credentials.

Dr. Watkins introduced DR. J. H. SOUTHALL, President of the Society.

REV. A. R. KENNEDY, of the Second Presbyterian Church, offered a prayer.

DR. C. WATKINS, Chairman of the Committee of Arrangements, delivered the address of welcome, an excellent article and replete with good points.

DR. J. H. SOUTHALL delivered the annual address, which was listened to with the closest attention.

The Committee on Credentials, made their report, which included forty-one delegates from nineteen societies, twenty-three permanent members, and twenty-four applicants for membership.

The President's address was referred to a special committee of three members.

During the afternoon session invitations to visit different institutions and places of interest, and telegrams from absent members were read.

Papers were read and discussed as follows: "Surgery of the Popliteal Space," Dr. J. E. Bennett; "Skin Grafting," Dr. G. W. Hudson; "A Case of Strangulated Inguinal Hernia in a Crypt Orchid," Dr. J. H. Debrell, Jr.; "Ligation of the External Iliac Artery for Traumatic Aneurism of the Femoral," Dr. R. G. Jennings; "A Case of Osteo-Sarcoma," Dr. C. L. Kirksely; "Radical Cure of Hernia on the Heatonian Plan," Dr. J. E. Bennett; "Notes on Cases of Placenta Prævia," Dr. S. Kirby.

At the evening session DR. E. CROSS, as Chairman of the Committee on Gynecology, read his address. It was followed by papers on "Laceration of the Perineum," Dr. J. T. Jelks; "Puerperal Convulsions," Dr. W. H. Hawkins; "Use of Ergot in Treatment of Puerperal Convulsions," Dr. A. N. Carrigan; "An Interesting Experience in Gynecology," Dr. J. R. Dale; after which the Society adjourned for the day.

The morning of the second day was consumed in transacting the business of the Society, consisting of reports of committees, officers, etc.

At the evening session the Nominating Committee reported the following officers for the ensuing year: *President*—J. M. Keller, Garland County; *First Vice-President*—G. W. Hudson, Ouachita County; *Second Vice-President*—J. M. Carrigan, Hempstead County; *Third Vice-President*—J. F. Blackburn, Franklin County; *Fourth Vice-President*—D. S. Mills, Jefferson County; *Secretary*—L. P. Gibson, Pulaski County; *Assistant Secretary*—E. Meek, Pulaski County; *Treasurer*—A. L. Breysacher, Pulaski County; *Librarian*—John Waters, Pulaski County.

The place of meeting next year to be the city of Little Rock, and the time to be the Wednesday next preceding the meeting of the American Medical Association in 1884.

The following resolution was adopted unanimously :

Resolved, That the State Medical Society of Arkansas not only heartily condemns the effort of any local or State body of medical men to break down or destroy the Code of Ethics of the American Medical Association, but pledges itself to encourage no medical school or college whose professors, one or more, indorse or favor such effort.

DR. MCGAVOCK spoke in encouragement of the election to the legislature of such delegates as would sustain a liberal medical law. He moved the President appoint a committee of five to address the medical men of the State to urge the importance of medical legislation. Carried.

Papers were read and discussed as follows : "Diabetes Mellitus, with Case," Dr. J. E. Bennett ; "Some Observations on Hydrobromate of Hæmatropia and on Jequirity," Dr. T. E. Murrell ; "Modus Operandi of Zymotic Agents," Dr. W. W. Hipolite ; "Influences of the Mind," Dr. G. B. Malone ; "Observations on Concussion of the Spine from Blows, Falls, and Collision," Dr. E. Bentley, U. S. A. ; "Laceration of the Cervix," Dr. J. T. Jelks ; "Hydrophobia," Dr. J. G. Eberle, and "Report of a Case of Ascites," C. L. Kirksey.

On motion, Drs. Orto and DuVal were appointed a committee to conduct the President-elect to the chair.

DR. SOUTHALL, the retiring President, with a few brief remarks, thanking the members for their universal kindness and appreciation of his efforts, recommended their new officer to their kindest consideration.

DR. KELLER, in assuming the chair, said that owing to the lateness of the hour he would make them no long speech, but merely bow his thanks for this honor conferred upon him—the greatest honor of his life.

On motion, the Convention then adjourned.

THE TORONTO MEDICAL SOCIETY.

(From our Canadian Correspondent.)

Regular Meeting, May 18, 1883.

I. E. GRAHAM, M.D., PRESIDENT, IN THE CHAIR.

AFTER some routine business DR. J. FERGUSON, M.A., read a paper on

PUERPERAL PYREXIA.

After setting aside conditions of elevated temperature due to inflammatory processes, he went on to show that in a strictly normal labor, followed by a strictly physiological state of the system, there should be no elevation of bodily heat. Of the causes giving rise to pyrexial conditions he referred somewhat fully to the following : 1. Cases where there is elevation of temperature from some derangement of the system, as constipation, urinary derangements of various kinds, arrested or imperfect action of the skin, and some abnormal state of the breasts as regards the secretion of milk. 2. Cases of pyrexia of a purely neural character. The reader of the paper held that during pregnancy there is a period of high tension ; and after labor a period of low tension. To this condition of general low tension many cases of pyrexia could be traced, as the functions of secretion and excretion were liable to be interfered with by it, in people of a specially anxious, irritable disposition. 3. Cases where high temperature was due to malaria. He thought that the influence of malaria had not received the attention it merited in connection with the puerperal state. He divided the cases into two groups : the acute, where the symptoms are somewhat similar to malignant ague, and chronic cases of malarial poisoning, where the symptoms were more like those of low typhoid fever. He thought that if the woman had once been affected with ague or lived in a malarial locality, the system might be so affected as to give rise to chills and fever after confinement, although not living in a malarial lo-

cality at the time of her delivery. He recorded three striking cases of this kind. 4. Cases of pyrexia caused by a deranged relationship between the absorption of effete matter and its rejection from the system. This loading of the system with effete matter might arise in two distinct ways, or by a combination of both : first, by an imperfect digestion or destructive oxidation of this effete matter after it had been absorbed into the system ; and secondly, by a retention of this waste matter in the system. These toxic materials circulating in the blood impressed both the secretory and trophic nerves, and in this way gave rise to constitutional disturbances more or less severe. 5. The last group of cases were the really toxæmic from putrid or septic conditions. This group was divided into those of soporæmia, due to the absorption from the genital tract of some dead poison ; and those of a true septicæmia. This latter might arise from local infection from the hands of the physician or nurse ; or the contagion come in contact with the lacerated tract through the atmosphere. It might also be caused by constitutional infection through the lungs. In this way the infection of measles or scarlatina could enter the system and produce septicæmia ; or even a case of measles or scarlatina as well as septicæmia, if the woman had not had a previous protection from these diseases.

The treatment recommended for soporæmia was frequent sponging of the body and intra-uterine washings, with good nourishment. For septicæmia the same plan was adopted, but quinine in large doses, twenty to thirty grains, three to four times in the twenty-four hours, if required, to control the temperature and septic conditions.

Correspondence.

A MISNOMER EXPLAINED.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR : The meaning of hy-dro-pho-bia is a dread of water, *not a disease* susceptible of connection by any absurd construction from a diagnosis of the *so-called* disease of canine madness, which exists only in the imagination. All persons, as well as animals, dread water or any drink when under the influence of excessive fear, as a morbid inactivity of the organs of the throat prevails which tends to quackle or choke, and this tendency in the canine race, after they have taken cold in wounds that produce spasms, is proverbial. What has become of the mad dogs? In their absence let us calmly consider a few facts, and ask ourselves whether ignorance and superstition have not something to do with increasing their number and magnifying the dangers accompanying their malady. Dogs are sometimes afflicted with a distemper. When young they frequently have fits, running wild, with glaring eyes and frothing mouth ; when old they have attacks of paralysis, and are reduced to a stupid, inactive condition, both of which have been called *rabies*. It is a common superstition, that should a dog go mad *after* biting a person, the latter will also fall a victim to rabies. Dogs suffering from wounds may take cold, and inflammation setting in, the nerves become affected, spasms ensue, saliva is emitted, water is avoided, the whole appearance of the animal suggesting madness. The great disproportion of the sexes, occasioned by the destruction of the female dogs, has a capricious influence with various effects, including that of amateness and jealousy, often making them irritable to strangers and to snap and bite them seemingly without cause, or at the least trifling annoyance even from friends. Persons taking cold in wounds have suffered in a precisely similar manner, with all the attendant manifestations of so-called rabies. The effect is the same as lockjaw, only that a wound from a rusty nail may, with inflammation from a cold, produce a stronger affection in

the region of the throat. The end of many diseases which afflict humanity is attended with spasms, saliva, and other symptoms of hydrophobia. A few incidents will illustrate:

Some years ago a man in Dorchester, Mass., was bitten by a cat, another in Boston by a rat, and several by rabbits, the bites producing spasmodic symptoms in all the victims.

Mad horses and cows have been known, their disorder (frothing at the mouth, etc.) being doubtless caused by a poisonous shrub eaten with hay. A father bitten by his child, from whose throat he attempted to remove diphtheritic formation, died from the wound. A blacksmith of Roxbury, Mass., sprained his ankle while attending to a horse; he took cold, inflammation ensued, then violent spasms, and paroxysms at intervals for a week preceding death. The newspapers of 1878 reported that last March, in New York, Mr. J. Russell was bitten in the hand by Thomas Kelly, while quarrelling with him; since then his finger, then his hand, then his arm were successively amputated. He finally died from the effects of the bite.

A farmer of Ohio died from the effects of a bite on the hand from an insane son. Some members of a family were poisoned from eating roast goose, which they imagined was bitten by a mad dog, and were undoubtedly under spastic delusion. Had these animals and persons been bitten by dogs, they would undoubtedly have been reported as victims of rabies.

A man was bitten on the hand by a dog in Kingston, N. Y., and after three years was seized with symptoms which were at once regarded as those accompanying hydrophobia by all the city physicians, who watched the case with much interest. Between the interval of spasms the patient was rational and quiet, partook of water and food at times, but *usually the sight or sound of water* threw him into violent spasms. The man recovered, and the physicians regarded it as *hysteria* with hydrophobia simulation, which they thought was merely mental.

A dog-trainer, of New York, whose intelligent experience was of long standing, did not believe such a disease as canine madness existed. He was bitten, and while suffering from the wound his attendants called the malady hydrophobia; it was in reality delirium tremens. Watts, of Boston, who has probably the greatest experience with dogs in the New England States, never yet discovered evidence of this so-called disease. It is true that cases have been reported in the medical journals, but generally with a protest from eminent authorities. One instance is that of a woman, whose malady was hastily set down by the physician as hydrophobia. He was deceived by a chronic case of hysteric fits.

What gives something of a quietus to this obsolete superstition is the fact of such innumerable cases of persons having been bitten all over the world by dogs with no serious consequences, which could be cited if space would admit, wherein rabies have been pronounced as absolutely existing in the animal and patient, without any foundation or fact. A single instance, for the present, gives the fancied ideal of a volume, which is from a person holding office in the Society for the Prevention of Cruelty to Children and Animals, who witnessed an extreme case, called rabies, of a dog in paroxysms, frothing and biting fences and everything in his way, and finally biting a lady severely, aside from which she experienced no ill effects, and lived thirty years thereafter. Last autumn, a lawyer, of New York, was ferociously bitten by a large dog, while entering the premises guarded by the faithful animal at night. He took care that he took no cold in the wound, and therefore no harm came of it. A lady, of Cambridge, Mass., bitten by a black and tan pet last winter, took similar precaution with like result.

Hunters and sportsmen who have been bitten by their own and other dogs repeatedly, under various conditions and circumstances, some attacks being mild, others ferocious and of a mysterious nature, attest that no

positive evidence has yet been produced to show that virus ever emanated from a canine's mouth.

The writer during his life has been surrounded by different species of dogs; his children and friends, as well as himself have often been bitten by them, sometimes severely; but by the exercise of every precaution against taking cold, no ill results have followed. If a wound be severe, first cauterize it, if possible; however this may be, the application of a poultice of flaxseed and slippery elm, saturated with laudanum, will remove all irritation. Many practitioners of Paris have for a long time doubted the existence of hydrophobia as a disease, and those of eminence, experience, and deep research of Europe and America, regard it now as fallacious; while observation, experience, and an intelligent domiciliary view by others, who have studied the subject-matter, see no reason why this phantom should be a synonym of hydrophobia, with any more sense, than to substitute hallucination for reality.

J. G. CLAPP.

[Our correspondent's statements are interesting, but they simply show that hydrophobia is a rare disease (which is well known), and that many bites are harmless or only cause a non-specific tetanus.—ED.]

POLYCLINICS, POST-GRADUATE SCHOOLS, ETC., AND THEIR RELATION TO THE MEDICAL PROFESSION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: A fertile source for the inspiration of lugubrious groans on the part of the medical profession are the perversion of charity and the development of pauperism among patients who are amply able to pay; and as these are great, if not the greatest obstacles menacing the success of those of us who, by a discriminating Providence, are compelled to practise among the middle and poorer classes, it therefore justifies a moderate protest against any institution whereby our means of gaining a livelihood are materially, and even seriously compromised by these unnecessary "long-felt wants."

I say they are unnecessary, advisedly, for there is no city in the world with better clinical advantages than New York, for the hospitals and dispensaries are numerous where the specialties and details of treatment can be studied.

Not only are there many clinics in the city where for a small fee any specialty may be studied, but in addition to this many physicians of recognized ability would gladly extend the courtesy of their ward and amphitheatre to the student, without hope of fee or reward.

The Polyclinic and Post-Graduate School inculcate upon the mind of the rustic physician from the wilds of Bushwick the principles of the various specialties, for a decided quid pro quo, by means of patients appropriated from us.

Gelatine-coated pills and the luxuries of the Pharmacopœia are not enough, but in addition, in seeking an obstetric practice, we must contend against placards in English and German, soliciting pregnant women to be treated gratuitously—if too poor to pay. Thrift in this instance assumes poverty for an evident advantage, for, if necessary, one of the "professors" will assist the pauper (?) if occasion requires it. Why, sir, in the present style, Tom, Dick, and their unmentioned friends can hire a back-room on the top floor of a tenement-house, and proclaim themselves "professors" and "specialists" in the New York Pauper Developing School, and who can interfere?

Let us hope, for the benefit of our profession, sadly lacking in numbers, that the two institutions heading this article will have the usual disagreement in their respective faculties, and then we may have two more of them, for we certainly need more colleges. There are, at the lowest estimate, nine houses in New York City

without a tenant in the shape of a medical man, and the druggists are overrun with counter-prescribing. Now, Mr. Editor, let me declare that I have no feeling of pique. I don't want to be a "professor." I don't want to write a book. I simply want to make a living, and let me here detail my experience of the past week :

I had a patient with a stricture, who is in an established business, with an income enviable to an ordinary medical man, and who paid me a good fee on every visit, and I know too he had no cause for dissatisfaction. He went to one of these institutions, where he found a "professor" who advertises in fact, but not in words (as they all do in a way), that he was a specialist and "professor" of venereal diseases. I lose my patient, the patient receives treatment gratuitously, congratulates himself on his business sagacity, and ever after becomes a medical "deadhead" for dispensary treatment.

The second case was one of pulmonary trouble, whose circumstances were on a par with the preceding case.

The third case, a married lady, also able to pay, went to the "professor" of — well, nails, who asked her under whose treatment she had been. She mentioned my name, whereupon the "professor" said : "Oh, yes ; we know him very well. He is a very good doctor—but he don't know anything about *nails*."

I must ask you, Mr. Editor, to pardon the space I have taken ; but I am sure that you will find there are others who feel as I do in this matter. And now for a remedy. Inasmuch as the success of these institutions means our loss, it is evidently the duty of every physician whose business is injured by them to do all in his power, consistent with business courtesy and gentlemanly courtesy too, to thwart their aims, *e.g.*, by persuading any of his patients who may have gone to either of the schools, to go elsewhere, etc., and in cases of interest alone, or in which an opinion is sought, to refer the case to some one of the dispensary physicians, specialists, or visiting physicians of the hospitals of this city, who are able men and who may not be "professors."

In closing, I may say that in this enlightened age this letter savors of the bigotry and intolerance of ages ago ; but this is an era of trades-unions, etc. However, your readers will judge as to the bigotry of ITIS.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 9, 1883, to June 16, 1883.

TILTON, HENRY R., Major and Surgeon. Granted leave of absence for four months. S. O. 136, par. 7, A. G. O., June 14, 1883.

APPEL, AARON H., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Dakota and assigned to duty in the Department of the East. S. O. 130, par. 3, A. G. O., June 7, 1883.

POWELL, JUNIUS L., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Texas, and assigned to duty in the Department of the East. S. O. 130, par. 3, A. G. O., June 7, 1883.

RICHARD, CHARLES, First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Dakota, and assigned to duty in the Department of the East. S. O. 130, par. 3, A. G. O., June 7, 1883.

Official List of Changes in the Medical Corps of the Navy for two weeks ending June 16, 1883.

KERSHNER, EDWARD, Surgeon. From Marine Barracks, Brooklyn, to the Navy Yard, Brooklyn.

TAYLOR, JOHN Y., Medical Director. From the Naval Hospital, Washington, to the Naval Hospital, Norfolk, Va.

SUDDARDS, JAMES, Medical Director. From the Naval Hospital, Norfolk, Va., and waiting orders.

TURNER, F. J., Medical Director. From the National Board of Health, and waiting orders.

MARTIN, CHARLES, Medical Director. From the Navy Yard, New York, and awaiting orders.

SPEAR, JOHN C., Medical Inspector. From the Naval Medical Board to the Navy Yard, New York.

DIEHL, OLIVER, Assistant Surgeon. United States Practice Ship Dale, to report to the Medical Board for examination, preliminary to promotion.

June 19, 1883.....	0	3	23	9	22	16	0	0

THE CHOICE OF CLOTHES.—Much has lately been said and written to show that the demands of fashion should yield to the laws of physiology in matters of dress. Public attention has been prominently and frequently directed to certain well-recognized reforms in garments, especially in those of women, which are of indisputable importance. The proposed improvements have mainly had reference to the shape and size of articles of apparel, and have chiefly been designed to prevent certain baneful constrictions and compressions, certain unscientific distributions of weight, and certain impediments to healthy movement and growth, which fashion has favored, but which are obviously, in the truest sense, unphysiological. But it must not be forgotten that, in human dress, intelligently adapted to its essential utilities, the materials of garments must be wisely chosen, and that the texture and color of clothes have as important bearings upon the health and happiness of their wearer as the mere "make" of his apparel. On these points, hygienic science has established certain definite and reliable conclusions. Whatever else may be said about clothes, their primary object is to protect against hurtful variations of cold and heat. All their other uses are either derived from, or are subsidiary to, their essential purpose. If utility strictly rule, it is clear that the material, texture, thickness, and color of clothes must be governed in accordance with their bearing upon the protecting function of dress, and that these must be specialized in conformity with experience to meet the necessities of different climates, and the requirements of various occupations. With regard to protection against extremes of simple cold, as distinguished from cold winds, wool is much superior, for equal thicknesses, to either cotton or linen. For protection against very extreme cold, besides wool, leather or waterproof clothing is useful. Wool is especially adapted for underclothing ; when protection against cold is particularly aimed at, all underclothing should be of this material. Against cold, cotton and linen, for equal thicknesses, are about equal in protective power. For protection against cold winds, leather and

India-rubber, according to Dr. Parkes, for equal thicknesses, take first rank; wool the second; cotton and linen taking the lowest places. For protection against extreme of heat, in the form of direct solar rays, the texture of clothes is practically immaterial; protection from this danger depends chiefly, if not entirely, upon color. White has the greatest protecting power, then gray, yellow, pink, blue, and black. For hot countries, white clothing is the best; next comes dress of a light gray or dust-colored shade, like the Indian "khakee." In the shade, Dr. Parkes found that the protecting effect of color against heat is not marked. Here the thickness and the conducting power of the material are the conditions which affect protection. With regard to the absorption of perspiration, the hygroscopic properties of woollen fabrics are well known. The water penetrates into the woollen fibres themselves, and distends them (hygroscopic water), and also insinuates itself between the fibres (water of interposition). In absorbent power for watery fluids, wool is greatly superior to either cotton or linen; it has been found that the hygroscopic absorption of woollen fabrics, as compared with those of cotton and linen, is at least double in proportion to weight, and quadruple in proportion to surface. This observation applies to cotton fabrics made of cotton fibres as ordinarily prepared. Cotton fabrics made of cotton fibres so dressed as to become "absorbent," as in those made for surgical dressings, would probably equal, if they did not surpass, woollen materials in hygroscopic affinity. Amongst the subsidiary functions of clothes are the effects of various dress materials upon the absorption of odors, and in protection against malarial emanations. These considerations respectively assume especial importance in some occupations and in some countries. Odors probably mark the diffusion of minute material particles. Their absorption by articles of apparel has been found to depend partly upon color and partly upon texture. Stark's observations show that the power of absorption of odors by dress fabrics, so far as color alone is concerned, is in the following order: black, blue, red, green, yellow, white. So far as texture is concerned, the absorption of odors has been found to be in proportion to hygroscopic absorption. Woollen materials take up odors best. With regard to the protective influence of various dress materials against the effects of malarial emanations, the late Dr. Parkes wrote: "It has been supposed that wearing flannel next the skin lessens the risk of malaria. As it is generally supposed that the poison of malaria enters either by the lungs or stomach, it is difficult to see how protection to the skin can prevent its action, except indirectly, by preventing chill in persons who have already suffered from ague; but the very great authority of Andrew Combe, drawn from experience at Rome, is in favor of its having some influence; and it has been used on the west coast of Africa for this purpose with apparently good results."—*British Medical Journal*, April 28, 1883.

GENERAL PRACTICE IN ENGLAND.—A "general practitioner" writes to the *Lancet* in the following strain, and doubtless his remarks will be re-echoed in many quarters of the globe, not excepting our own country. Dr. Hickman, in an able and thoughtful address to the Harveian Society, pointed out some of the practical grievances of the general practitioner, arising from indiscriminate gratuitous medical aid supplied by hospitals and dispensaries, from the too cheap medical attendance given by provident dispensaries, and from various modes of low practice pursued by men who live by underselling their medical brethren.

Mr. Burdett, in the *Nineteenth Century*, advocates various reforms in the working of hospitals, which at present defraud the profession and the public; for a large and increasing proportion of the patients are quite unworthy of charitable aid, and such patients defraud the hard-worked junior members of the staff of the re-

muneration which is due to skilled work. They defraud the general practitioner of his fees by leaving him and getting gratuitous medical aid. They defraud the subscribers who give their money to be expended solely for the benefit of the needy. After due consideration of the various aspects of the question, Mr. Burdett thinks that medical men should refuse to do gratuitous work. The expenses of medical education and of living have greatly increased during recent years, and yet medical fees are sinking lower and lower. The very moderate fees formerly paid cheerfully or gratefully, are now given grudgingly or objected to. The public go to the cheapest medical market. Hospitals and dispensaries give them what they want for nothing. Provident dispensaries supply them at a price less than is paid for beer, and numerous cheap dispensaries give for sixpence or a shilling what used to cost from half a crown to five shillings. The effect of all this on general practice is evident. Many medical men hardly know how to make a living. The value of medical attendance is lowered in the eyes of the public, and an honored and learned profession sinks to the level of a badly paying trade.

Mr. Burdett wisely advises medical men to cease gratuitous work. As regards the vexed question of provident dispensaries, greater discrimination should be exercised regarding the admission of members, and the remuneration to the medical officers should be increased.

PHYSICIANS' PRESCRIPTIONS.—A rather curious lawsuit lately took place before the justice of the peace at St. Germain, in which a pharmacist was prosecuted for having refused to give up a prescription that was taken to him by a patient. The patient claimed the prescription as being his property, which the chemist contested; but the tribunal decided otherwise, and the prescription was restored to the patient. The *Société de Médecine Légale*, commenting on the case, was of opinion that, although the decision of the judge was unassailable from a legal point of view, yet it was considered that the restitution of a prescription was attended with great inconvenience, as the patient may take it to other chemists successively, and have it made up oftener than is necessary or good for him, without any reference to the medical man who gave him the prescription. Thus it has lately happened that a female patient spent one thousand eight hundred francs for the purchase of morphia for hypodermic injections, which had been only a few times prescribed for her, but which she ultimately employed on her own account. The result was that she became insane, which the medical experts who were required to give their opinion attributed to the abuse of morphia. Whereupon the husband sued the chemist, but a case of the kind not having before been brought to the notice of the court, the present prosecution has been remanded for legislation.

PINUS CANADENSIS IN DIPHTHERIA.—Dr. D. M. Cool, of Wanly, Iowa, sends a suggestive letter describing the results of seven years' experience with diphtheria while practising in Chicago. During this time he saw several hundred cases of all grades of severity. Before adopting the treatment which he now recommends Dr. Cool had used sulphurous acid, chlorate of potash, iron, quinine, alcohol, etc., with fair success. He writes: "There came a time when my per cent. of deaths became much too large to be satisfactory. I was called quite early in the morning to see a child of Mrs. C—, three years of age. Two doctors had just left it saying it could not live until night. While thinking over in my mind what I should do in the case, a thought struck me to try extract *Pinus Canadensis* fluid. Acting upon this thought I wrote for Keneday's extract to be applied to the throat by means of a soft swab once an hour. Internally I gave Labarraque's solution chlorinated soda, five drops once in two hours. With this I gave milk, quinine, and brandy. I called in the afternoon and was agreeably surprised to find the patient better. From that time to this, in a large practice, I have

used the following: *R. Ex. Pinus Can. fl. 5 j.*; carbolic acid (95%), *gtts. x.* *M. Sig.* Apply (by means of a soft swab or camel's-hair brush) to the throat once an hour. Also, internally, Labarraque's sol. chl. soda, $\frac{5}{2}$ ij.; give, according to age, three to ten drops in water once in two hours. This, with the usual support, has been my treatment, with only the loss of four cases." A history of these cases is given, showing that in nearly every case the remedy could not be satisfactorily applied. Dr. Cool concludes: "I am not a believer in specifics, but this comes as near to one in my hands as well as in the hands of the physician whom I have given it to, as quinine is to a well-marked intermittent. In order to make it successful it must be applied frequently and thoroughly to the patient's throat, at least once an hour during the day, and once in two during the night. So far as I know, I am the first to use it in diphtheria. I had used it in leucorrhœa with fair success. The solution of chlorinated soda is useful through the chlorine it contains. In addition to this I apply salt to the throat externally."

[Dr. Cool's letter suggests the query (whether any good disinfectant applied with such thoroughness will not secure equally favorable results.)]

A SUCCESSFUL CLOSURE OF A RUPTURED PERINEUM, WITH COMPLETE LACERATION OF THE SPHINCTER ANI, WITHOUT CONSTIPATING THE BOWELS OR THE USE OF THE CATHETER.—Dr. W. H. Johnston, of Selma, Ala., writes: "The patient's bowels were thoroughly evacuated the day before operating, and on the morning of the operation were again emptied by an enema of warm water. The rents in the bowel and perineum were closed with three deep silver sutures, and then two superficial sutures of horse-hair were used, which closed every part perfectly; legs were tied together. Operation performed on April 25th. Patient directed to have a cupful of tepid water, with a tablespoonful of listerine in it, and to use this to wash out the vagina every time the bladder should act. On the morning of the 27th an enema of warm water was gently thrown into the bowel, followed by the first action since the operation. On the evening of the fourth day two teaspoonfuls of magnesia were given; bowels acted three times during night; patient was directed to use an enema of a small quantity of warm water whenever she felt that her bowels were going to act. On the morning of May 1st, six days after the operation, the sutures were all removed and union was perfect. This patient had been unable to exercise any control over the flatus, and whenever her bowels were loose could not retain their contents. My only reason for reporting the case, is that heretofore it has been generally believed necessary to use the catheter for three or four days to empty the bladder, and also it was a rule to constipate the bowel, neither of which procedures seem to be necessary, and the omission of which adds greatly to the comfort of the patient."

THE PRACTICE OF MEDICINE IN THE MIDDLE AGES.—In Mr. Fort's interesting work on "Medical Economy in the Middle Ages," some interesting facts are given regarding the practice of medicine in the Two Sicilies. Long before the healing art had been replaced on anything like a rational basis in the rest of Christian Europe, a great deal of the ground lost since Galen was recovered in the kingdom of the Two Sicilies. Here the presence of a large Mohammedan population offered facilities for the study of Arabian science, which had preserved and in some directions augmented the knowledge gained by the Hellenic anatomists and botanists and by Greek empiricism generally. Some of the Sicilian laws relating to the practice of medicine and to sanitary regulations attest a surprising degree of knowledge and sagacity on the part of the legislator. For instance, a decree of Frederick II. prohibits, under severe penalties, the sale of diseased pork and deleterious bread in his Sicilian and Neapolitan dominions. Another

sanitary ordinance by the same emperor orders the dead bodies of men or animals to be buried in remote localities or carried out to sea and sunk. Another rescript of this sovereign's prescribes minute rules for the guidance of physicians in their practice. They were required to give gratuitous attention to the indigent sick, and a maximum fee was fixed for their professional services to the well-to-do. The fees of apothecaries were also specified, and physicians were sternly admonished against secret association with druggists to defraud patients by illegal additions to the legal cost of compounding remedies. In other parts of Europe, however, medical honoraria seem to have been generally determined by special contracts, often contingent on the recovery of the patients. The sums thus pledged, in written instruments still extant, for restoration to health seem very large, when we remember the purchasing power of money at the time. That cures, real or supposed, were frequently accomplished, notwithstanding the ridicule heaped upon the medical fraternity by Petrarch and other writers, may be inferred from the enormous fortunes accumulated by some practitioners.

THE POWER OF DRUGS.—Many men doubt the efficacy of drugs because their efforts have not been attended by success. But this want of success is more often not the fault of the remedies themselves, but the fault of the prescriber, who fails, from the want of an almost intuitive tact, in the selection of the best drug, or drugs, and in their proper combination and dosage. How frequently one sees a patient, who, under the treatment of one man, drags on wearily from week to week, no better—often, indeed, going from bad to worse—under another man's care rapidly improve, and from the very rapidity of recovery giving proof of the efficacy of the drugs employed. Instead of lowering the estimation in which our materia medica is held, increased knowledge is likely to carry it to a still more honored position, when the powers of each drug, from accurate observation, become more thoroughly defined.—*Medical Press.*

THE NEW CODE AND THE SENTIMENT IN THE WEST.—Dr. W. B. M——, of Washington Court House, O., writes: "I am moved to pen the enclosed effusion because I am convinced that the idea (which seems to obtain in New York City) that the profession throughout the country, and especially throughout the West, is wildly opposed to the new Code, is an erroneous idea. I am certain that the opinions expressed by the medical press in the West against the new Code do not reflect the sentiments of the majority of the practitioners. Here almost all the regular physicians are in favor of the new Code. I hope and feel certain that Drs. Agnew, Roosa, and their allies, will succeed in the battle which seems to be going on. It is only a question of a little time when the whole profession will stand by them."

FATAL CASE OF CHOREA.—Dr. J. A. Fordyce, of Hot Springs, Ark., late House Physician to the Cook County Hospital, Chicago, sends us a very complete history of a case of chorea which ended fatally. The case occurred in the Cook County Hospital under the service of Dr. F. Heurotin. The patient was a Swedish girl, unmarried, twenty-two years of age, who had had good health except for a short attack of chorea a year before. Four weeks before admission to the hospital the fatal attack began. The movements were not very bad until a few days before admission. There was some swelling and pain in the knees and ankles, and a systolic murmur at the apex and base of the heart. The movements were very violent. The patient had a fever; grew weaker. Salicylates were given and enormous doses of chloral to secure rest. Their effect was only palliative. The patient died within eight days. No autopsy was allowed.

EXTIRPATION OF A LARGE GOITRE.—M. Labbé, of the Lariboisière Hospital, recently extirpated an enormous goitre from the neck of a middle-aged woman. The

operation was rendered imperative from the condition of the patient, who was being gradually asphyxiated. Knowing that the loss of blood would be fatal to a person already so much reduced, he decided on practising transfusion immediately after the operation. One of the students generously furnished the blood. The tumor was excised, transfusion practised, and the woman recovered. This noble act of the student was highly praised, and the Legion of Honor will, it is said, be given to him as a recompense.

THE HOSPITALS OF ROME.—In Rome I visited the Hospital S. Spirito in Sassia and the great lunatic asylum (Ospedale di S. Maria). It is surprising what a large number of hospitals Rome possesses. Thus it has among its large hospitals one for internal diseases only, two for surgical diseases, one for skin diseases, and one lying-in hospital. Besides these large institutions it possesses any number of smaller ones for convalescents, fever patients, scabies, chronic incurables, etc. Nine hospitals for strangers (German, Spanish, Armenian, Portuguese, Egyptian, etc.) swell this number. Ospedale di S. Spirito is the largest hospital of Rome, and at one time was the largest in the world. It was erected by Innocent III. to serve both as a hospital and a foundling institution, probably the first foundling hospital of which we have record (1200). It possesses an income of one-half million francs yearly, and receives 200,000 francs additional from the State. It serves only as a hospital for internal diseases, has sixteen hundred beds, and about twenty thousand patients yearly. Malarial fevers, phthisis pulmonalis, pneumonia, and intestinal troubles furnish the largest number of patients. Passing through the wards we are confronted by the malarial cachexia on every side, and our guide was kind enough to allow us to palpate some immensely enlarged spleens. Large doses of quinine and some preparation of iron (I think the iodide is preferred) is the treatment most generally adopted here. The Roman Campagna furnishes this large number of patients suffering from malaria. Phthisical patients are kept entirely separated here in special rooms. On the whole, I must say that I was impressed rather unfavorably with its wards, the light being very poor, and the ventilation not of the best; the age of the institution must, however, not be forgotten in passing judgment as to its merits.—E. E. SADTLER, in *Cincinnati Lancet and Clinic*.

ST. ANDREA HOSPITAL, GENOA.—The St. Andrea is our very ideal of what a hospital should be. Beautifully situated on a hilly projection of the Genoese coast, looking out upon the calm blue expanse of the Mediterranean, it will be a very paradise for the sick. The very sight of the calm repose expressed on every side, the salt breezes laden with health, will do more toward healing the sick in this place than any medicine that man has ever had at his command. Genoa seems to be a second Cincinnati as regards the lavish generosity of its citizens. Here we have a woman, the Duchess of Galliera, building three hospitals, one for scrofulous diseases, one for chronic incurables, and this one in progress—the St. Andrea—the model of all models. She contributed 5,000,000 francs for its construction, and ordered neither pains nor money to be spared to make it perfect in every respect. Six years have already been spent working at it, and two more years will be required to complete it. At present work has been stopped for a time for lack of funds, the private secretary of the duchess having decamped with \$100,000 of the money entrusted to his care.—SADTLER, in *Cincinnati Lancet and Clinic*.

INSANE FROM FRIGHT.—There has just died at the Charenton Asylum, near Paris, a man who, thirty years ago, was condemned to death at the Seine Assizes for the murder of an old gentleman. The case had excited considerable interest, and the court was crowded with spectators. Among the persons standing immediately behind the criminal, who was flanked by a pair of gendarmes, was an employé of the *Presse* newspaper, who

had somehow contrived to wriggle himself into that position without attracting notice. Scarcely had the sentence been pronounced, when this *Presse* employé, moved, as he afterward explained, by an uncontrollable impulse, passed the side of his hand over the prisoner's neck in imitation of the keen blade of the guillotine, at the same time emitting a whirring sound. The man just convicted instantly fell forward with a shriek of terror, and the by-standers, indignant at this heartless and shocking act, rushed upon the *Presse* man and roundly abused him, who also was subsequently condemned to two years' imprisonment. His victim never recovered the shock, but remained insane until his death. He was pardoned by the emperor, and confined, first at Bicêtre, and afterward at Charenton, where he has just expired. He had the delusion that he had been actually beheaded in the Palais de Justice, and when relating the story was in the habit of imitating the sound that haunted him for thirty years.—*Gaillard's Journal*.

THE NEW YORK MEDICO LEGAL SOCIETY.—At the stated meeting of this Society, on May 3d, District Attorney George B. Corkhill read a paper entitled "Insanity as a Defence for Crime." The reader referred to the great extent to which insanity has been used as an excuse for crime. Speaking of the cases in which men who avenge the ruin of their domestic bliss by killing the destroyer, and are acquitted on the ground of emotional insanity, Colonel Corkhill said: "Would it not be more creditable to our juries and more honorable to the administration of justice to let the jury say by their verdict that the justification for the crime was in the character of the act which provoked it, and not encourage and countenance this plea of insanity by a verdict as contrary to their oaths and the law as would be the former? If they must apologize, let it be the more manly apology of open refusal to find a prisoner guilty under such serious provocation, rather than to shield themselves behind a defence in which neither they nor the community which they represent believe."

Colonel Corkhill did not think that insanity should ever be allowed as a plea of defence for crime in the trial of the prisoner under the indictment. When a prisoner proposes to defend his crime on the ground of insanity, a jury should be specially chosen for their fitness to try the special plea, and if the prisoner, after trial, is found to be insane, then he should be confined in an insane prison a certain time commensurate with the character of his crime; if, however, the verdict of the jury declare the prisoner to be sane, the plea of insanity should not be allowed on the trial of the cause. It is not a question whether the plea of insanity should be allowed as a defence for crime, but whether some means cannot be devised under the law by which its existence can be rationally and honestly determined.

Mr. Corkhill's view that the question of insanity should be determined by a special and expert jury is one which has frequently been urged.

A NEW DISCOVERY IN THE PHYSIOLOGY OF THE HEART'S ACTION.—Dr. Thomas J. Mayo, of London, sends us the report of a series of experiments upon the action of the frog's heart made by him in the Berlin Physiological Laboratory. He has succeeded in unearthing a new phenomenon in the physiology of the organ in question. Heretofore it was always found that the pulse-waves of the frog's heart never varied in elevation whether excited by strong or weak electric currents, i.e., an electric current in passing through the heart either produced a maximal contraction or none at all. This was held to be a characteristic mark in the behavior of the heart, which differentiated it from a skeleton muscle. Dr. Mayo has found, however, that under certain conditions this differentiation entirely disappears, and that very striking contrasts between high and low pulse-waves can be called forth in the frog's heart by strong and weak electric currents.

IMPREGNATION OF A COMPLETELY PROLAPSED UTERUS—ABORTION—EXTIRPATION OF UTERUS AND OVARIES, WITH A LARGE SECTION OF THE POSTERIOR WALL OF THE VAGINA—RECOVERY.¹

By J. T. STEWART, M.D.,
PEORIA, ILL.

MRS. C—, aged thirty-five, of German birth, from Peru, Ill., the mother of five children, was admitted to St. Francis' Hospital, May 23, 1882. She was suffering from extreme procidentia, the uterus and bladder protruding half-way to the knees. Her constitution was good, but she was in an irritable condition and very despondent. I put her on general treatment, to allay this irritation and build her up, until June 12th. At this time I operated on her for narrowing the vagina. The operation was a partial success. It retained the uterus *in situ* four months; the organ then burst through. In the early part of February last she returned to the hospital. The procidentia was even worse than before. The neck of the womb was enormously enlarged, measuring about three inches in diameter, and the entire surface in a state of ulceration.

As before stated, she was the mother of five children, aged respectively fifteen, twelve, ten, and six. She had a miscarriage four years ago at four months. After the birth of the second child the womb prolapsed, protruded outside the body, and was in this condition most of the time until after the birth of the last child, when it came down and remained in a state of procidentia continually. Therefore, according to her account, she had this procidentia for twelve years, and for the last six years continually. It probably resulted from a laceration of the perineum during her second confinement. After the trouble first began she bore three children. It is hardly credible that she should become pregnant while the womb was protruding continually; but that is her statement, and that she miscarried at four months.

Seeing she could be benefited by no operation, except the removal of the entire organ, I so informed her, and laid before her the full extent of the danger of the operation. She said she would rather die than live in the condition she was then in, and insisted on my doing it. I therefore prepared for it, and on February 13th performed it.

The operator was efficiently assisted by Drs. J. P. Johnson, J. Murphy, and J. Studer, members of the hospital staff.

The patient being etherized, the first step consisted in drawing the mass well downward and forward and making a transverse incision on the posterior part through the mucous membrane a little below the junction of the cervix and the body of the womb. Then a longitudinal incision to near the rectum. The uterus was then seized by the fundus and drawn downward and forward through the opening. The uterus with its appendages were thus fully exposed. On one side a ligature was placed just outside the ovary; the ligament was divided inside the ligature, and the broad ligament divided to the uterus between the ovary and the round ligament, leaving the

ovary still attached to the uterus. A ligature was next placed around the round ligament near the uterus, and another embracing the rest of the broad ligament the same distance from the uterus, perhaps half an inch. These parts were then divided. The other side was treated the same way.

The next step was to separate the bladder from the uterus. Here was the great difficulty of the operation, and it was very great. The whole posterior part of the bladder had become firmly adherent, not only so but it had lapped round and adhered to at least two-thirds of the circumference, of the womb. A sound was introduced as a guide, and the dissection began. By the exercise of extreme care and long perseverance this was accomplished without wounding the bladder. The uterus was then severed from its attachments to the vagina. The posterior wall of the vagina being thickened and prolapsed was removed by the scissors. It was then found that at the upper part, where the uterus was separated from its vaginal attachment, the peritoneum was loosened for quite a distance. This was secured by three stitches.

The bladder was then replaced, a wad of absorbent cotton placed over the vulva, and some cotton wadding placed over the abdomen, which were kept in place by a T-bandage.

This completed the operation, which occupied an hour and ten minutes. By this time the patient was in an extremely exhausted condition. She was put to bed, warm blankets applied to her, plenty of fresh air admitted, and, as soon as she could swallow, stimulants given freely. She revived in an hour or two and began to suffer pain, when an opiate was administered. The posterior wall of the vagina was removed for two reasons: one was because it was greatly thickened and prolapsed; the other was to give a fresh surface for the bladder to rest upon.

The posterior surface of the bladder in removing it from the womb was denuded; the posterior surface of the vagina was denuded. In lying on her back these two raw surfaces fell together and adhered, thus making a firm floor to support the intestines, and, of course, the whole posterior surface of the bladder being adherent to the posterior surface of the vagina prevented it from prolapsing.

There was no need to close the external parts. By leaving them open it gave better drainage, and there could be no possible object in closing them. The external parts are now natural. From the outside it is about an inch to the adhesion in the centre. On each side it is about an inch and a half. The adhesion is perfect and complete, closing the whole passage. No catheter was left in the bladder, and it was not necessary. The urine was very easily drawn off. I instructed one of the Sisters how to do it, and she drew it off four times in twenty-four hours for about two weeks, after which time the patient passed it herself without difficulty. I may say here that the secretion of urine was copious all the time. I now give, from notes taken at the time, an outline of the progress and treatment of the case. The operation was done on the afternoon of February 13, 1883.

February 14th.—Fully recovered from the shock of the operation. No fever and not much pain. Continued cotton to abdomen. Applied absorbent cotton to vulva, with two thicknesses of lint moistened with carbolized water over it. The dressing secured by a T-bandage. One-fourth grain opium every four hours.

February 15th.—Patient resting well and feeling com-

¹ A paper read before the Illinois State Medical Society, at Peoria, May 16, 1883.

fortable; respiration normal. Pulse, 110; temperature, 102½. Skin moist. Continue opium, half grain every four hours. Dressing same.

February 16th.—Pulse, 118; temperature, 102°; great thirst. Continue opium and dressing same as yesterday.

February 17th.—Pulse, 80, very weak; temperature, 98½°. Pain and tympanites; vomited occasionally through the night. One-grain opium pill every four hours; drop doses of Fowler's solution every three hours. Gave pounded ice to quench thirst, which was intense.

February 18th.—Pulse, 100, weak; temperature, 98°. Vomiting ceased; diarrhoea. Continue opium; continue ice. Gave Liebig's extract beef and brandy.

February 19th.—Pulse, 80; temperature, 98½°; thirst intense; severe pain in abdomen by spells. Tympanites continued. Ordered one grain opium every two hours; arnica flower poultices to abdomen. Beef extract continued. Champagne given in place of brandy. Ice continued *ad libitum*.

February 20th.—Pulse, 80; temperature, 98½°. Great tympanites and pain. Opium, beef extract, and champagne continued; also the following mixture:

R. Fennel seed	ij.
Manna	ss.
Magnesia carb.	ij.
Tinct. asafetida.	ss.
Barley water	℥℥.

Mix. S.—Tablespoonful every three hours.

Injection into the bowels of asafetida mixture and spirits turpentine.

February 21st.—Pulse, 90; temperature normal; little pain; tympanites increased. Gave an injection of castor-oil and turpentine in soapsuds. It passed off without effect.

February 22d.—Had a restless night; temperature, normal; pulse, 100; tympanites slightly reduced; pain increased. Gave one-fourth grain morphia hypodermically. Continue opium pills. Applied turpentine to abdomen, to be followed by mercurial ointment. A dessert-spoonful of the following mixture every three hours:

R. Spts. turpentine	2 ss.
Ol. sweet almonds.	℥ivss.
Ol. anisi	gtt. ij.
Aq. anisi	℥ij.

Pulv. acacia q.s. to make an emulsion.

Beef-tea and champagne given freely.

February 23d.—Pulse, 90; temperature, normal; tympanites still great; some pain. Repeat hypodermic injection of morphia; continue emulsion. Apply turpentine again, followed by mercurial ointment.

February 24th.—Decidedly better; temperature, normal; pulse, 90; tympanites less; pain less; suppuration healthy. I will say here that tepid carbolized water injections were used daily to cleanse the wound until it healed. Continue treatment as before.

February 25th.—Much the same as yesterday. The intense thirst which has been persistent from the beginning now abating. For this ice has been allowed freely, which is still very grateful.

February 26th.—Still improving. Stop mercurial ointment and apply cotton over abdomen. Emulsion once in four hours, opium at night.

February 27th.—Progressing favorably; bowels regular, as they have been most of the time. Stop emulsion, ten grains quinine during the day and opium at night.

Suffice it to say that from this time on, with the exception of three or four days in the latter part of the third week, during which she had a rather severe diarrhoea, with an almost total cessation of the action of the liver, she improved steadily and very satisfactorily. At the end of five weeks she could sit up a little. In seven weeks she could easily walk across the room alone, and in two months after the operation she was perfectly well.

A few days later she was allowed to go home. That is about a month ago. She says, in a letter she wrote a few days since, that she is as well as she ever was in her life. The drainage-tube was not much used, for the reason that it was not necessary.

HOW TO PROCURE THE BEST POSSIBLE PHYSICAL CONDITION AFTER PARTURITION.

By JAMES D. MACGAUGHEY, M.D.,

WALLINGFORD, CONN.

THE above title headed a paper read before the New York Academy of Medicine, Section in Obstetrics, April 26, 1883, by Dr. R. Tauszky. Then came the important questions, "Why is it that almost every woman, as soon as she becomes a mother, begins to suffer from some pelvic disease?" referring to the very large percentage of gynecological cases in which the morbid condition present could be traced directly to childbirth, and then followed logically the second question, "By what means can the occurrence of these conditions be prevented?" The author proceeds to state those things which will secure the answer to the last question, and in the main I agree, and would take no exceptions, only in regard to his remarks on closing all wounds and suppressing the lochia.

A rapid review of his paper will show where we diverge. In regard to absolute cleanliness on the part of the accoucheur, and the use of carbolic solution for disinfecting the hand before undertaking a case, its importance is thoroughly recognized, even by the skeptic, who, if conscientious, washes his hands in a carbolic or other disinfecting solution, to give the patient the benefit of the doubt. Certainly, all instruments and articles used about the woman should be cleaned and disinfected. The bowels should be properly attended to prior to confinement. Careful dilatation of cervix facilitates the relaxation of the os, and gently pushing up the anterior lip will certainly save it from undue pressure and remove a minor cause of dystocia. Of course, tough membranes should be ruptured, chloroform given if necessary, and, as for the forceps, we all know their value, and, I hope, when and how to use them. As for waiting for the umbilical vessels to stop beating before separating the child from the mother, it would seem to be a foolish delay; if the child is breathing good, and shows active signs of life, separate at once and let the attention be turned to the mother. The writer of the paper in question forgot to mention one important manœuvre which would certainly help him out in his idea of suppressing the lochia, viz., to keep the left hand pressing firmly down on the womb, following it up closely as it grows smaller in expelling the child, and directing an attendant to continue firm pressure while the cord is being separated and the child is receiving proper attention. This way of managing the second stage of labor is very essential in producing the permanent contraction of the uterus, and in causing it to cast off the placenta. Crede's method of expression of after-birth is good, if there is a little tension on the cord; at best, it is an overrated measure.

As for examining the genital passages of *all* puerpera after removal of secundines, and directing that all slight lacerations should be promptly closed, the advice is very good on paper, but very awkward and difficult and often very unnecessary at the bedside; besides, the "meddlesome midwifery" of exposing all women, and of closing slight lacerations or wounds, would involve more, much more, danger to the patient than letting them alone.

The binder should never be dispensed with, the child applied to breasts early, and in the puerperal condition careful disinfection should be strictly observed. But here Dr. Tauszky and the writer diverge, because his advice which follows I think fraught with danger, interfering with nature and the natural post-puerperium physio-

logical processes, and going entirely too far when he remarks that "a little hemorrhage after parturition is a dangerous thing and should be arrested;" and that the "accoucheur should be regarded as guilty of malpractice who would permit a slight quantity of blood to escape from the genital organs of a woman for days after parturition." He maintained that not a *single drop of blood should appear after the completion of the third stage of labor, and that napkins removed should be perfectly free from color* (italics my own); that should they be colored, the physician should at once institute an examination with reference to the source from whence the blood came, and set about arresting it. This point was made more positive in the discussion which followed this extraordinary statement by Dr. Carpenter asking Dr. Tauszky if "he wished it to be understood as saying that not a single drop of blood should be seen in the discharges after the completion of the third stage of labor?"

Dr. Tauszky replied that "no bleeding whatever should take place after labor; that not one single drop of blood should be seen." Surely the days of extremists are here, for in my obstetrical reading I fail to recollect of having seen any such statement made by any acknowledged authority, either in this country or Europe.

I have always thought that it was a well-understood fact, that no one ever questioned, that a sanguinolent flow always follows the parturient state, and that it is necessary. Upon a matter so well known and recognized, it seems hardly worth while to take up space to quote authorities, but on account of the importance of the matter, and of the necessity of fixing the attention on the subject, I will do so briefly. Ramsbotham, American edition, p. 165: "The sanguineous discharge does not cease as soon as the placenta is expelled, *nor ought it to disappear suddenly*; but a continual oozing goes on from the uterine vessels in a greater or less quantity for some time after delivery." It is unnecessary to quote Playfair, Meadows, Meigs, Smith, Barnes, and a host of authorities whose combined dicta have settled the question long ago. Here is Leishman's opinion, third American edition, p. 591: "Efficient and rhythmical contraction of the uterus prevents the flow from becoming so profuse as to be dangerous, but still a certain amount of discharge goes on from time to time; and, indeed, it is well known that the maintenance of this discharge for a certain time after delivery is, to some extent, a guarantee of the favorable progress of the case." Recollect, Dr. Tauszky puts his foot, figuratively speaking, on the womb, and says "not one drop" shall you pour forth, and, still figuratively speaking, if he keeps up the practice will undoubtedly put his foot into it many times. Well, to follow up Leishman, to see how his ideas coincide with the shut-off method. He (Leishman) advises on the second day after confinement, that the woman make water on her knees. Why? Because it (the position) "permits escape of any portion of fluid which may have accumulated in the cavity of the vagina." It seems to me to be ridiculous—a work of supererogation—to discuss this matter, so universally well known and settled. But if a subject is allowed to come before the New York Academy of Medicine and be discussed, and the proceedings be published in a journal so extensively read as THE RECORD, and, moreover, as the practice was not condemned by those present who took part in the discussion, I deem it necessary, from the intrinsic importance of the subject, to call attention to the paper of Dr. Tauszky, owing to the influence it may have upon others who in their zeal are anxious and waiting to adopt some new and novel manner of treating the parturient woman—to call attention to a treatment which is the very opposite of rational, and in the face of well-known physiological facts, that such "meddlesome midwifery" will do just what we don't want it to do.

Those who would wish to suppress immediately the lochia should read Cazeaux on this subject, and, recognizing the increased amount of liquid in the uterus, also

its enormously increased solids, as compared with the condition just before and just after confinement, can easily convince themselves that the physiological function of the lochia should remain strictly undisturbed as long as it keeps within normal limits. I believe, after all, it is impossible, even if desirable, to suppress the lochia after the delivery of the placenta, and the attempt to do so is dangerous. After the third stage, although the womb may have at the time been thoroughly contracted, yet in most cases *there will be a subsequent relaxation*—impossible to prevent owing to circumstances unavoidably appertaining to the woman's heredity, previous health, and many conditions vitiating health prior to labor; the blood will continue to collect in the uterine cavity as it has slowly transuded from the uterine surface, and Dr. Tauszky can't help it or prevent it, and after a rest will be expelled. This flow, commencing some little time after completion of the third stage, continues from twelve to fifteen hours, when it loses its consistency, "the color becomes lighter, and after a short time is changed into a bloody serosity," of course indicating the natural preliminaries of involution and the reproduction of the decidua membrane; and a man that would interfere with this natural process—a process which nature elaborated and perfected in the grand scheme of restoring the puerperal womb to its healthy size and condition—ought to be mulcted for malpractice. The close connection between the secretion of milk and the effect beginning lactation has on diminishing or suspending the lochia shows that you might as well in healthy cases try to suppress the milk for fear of mastitis, as to suppress the healthy lochia for fear of some imaginary evil. After labor the size of the womb must be reduced. Suppressing the lochia would be dangerous, for the reason that in uterine involution, much that is discharged per vaginam would have to be carried by absorption through the circulation, unduly and unnecessarily loading the blood, and throwing a heavy burden upon the eliminative organs of the economy. By its natural retractile power the liquids are thrown out as well as by direct elimination. As Cazeaux remarks, the "uterus retracts its walls gradually, disgorge fluids they had imbibed, and these naturally run toward the central cavity. So long as the large venous canals in its (the womb's) substance are not empty, the discharge continues of pure blood; later it is composed of serum, together with the detritus of the ovum and the mucosities of the organ"—beautiful things to be shut up in the womb and carried out through the general system instead of a "short cut" by the vagina!

Often unavoidable coagula will remain or form in the uterus a day or two after labor, and intravaginal injections fail to dislodge them, and if the lochial discharge is rudely shut off, these clots will decay, as well as all other suppressed discharges, the flow becomes fetid and a cause of puerperal trouble. Then there is a condition of the womb after confinement where the discharges are abundant and the womb high up, called by Leroux humoral engorgement, which he declares depends upon, in his estimation, the fact that "the blood-vessels and pores of the womb, from being distended with blood, do not become empty as soon as usual, because the contractility of tissue is not then active enough to expel it, for the walls of the uterus constitute a true sponge whose meshes are composed of muscular fibres, and which must retract forcibly, so as to express liquids contained in the vessels and vacuities which they form." And so abundant is the flow sometimes that, according to Cazeaux, "the discharge might very readily be mistaken for flooding occasioned by retention of some parts of after-birth or coagula, the more especially as it is accompanied at times by sharp after-pains. But if a finger be passed into the interior of the uterus and no foreign substance found, with assistance of conjoined manipulation he will be easily satisfied that the unusual size of the organ depends on enlargement, and the bloody discharge is beneficial. In such a case the absolute rule of shutting off

the post-parturient discharge would be folly. The prevention of such a condition is difficult if firm, inherent contractions are absent or impaired from some unknown or unavoidable cause; as some wombs, as no doubt has been the experience of every one, will contract and remain firm, while others will contract and subsequently relax. To save prolixity, I will not undertake to give an opinion in regard to the question, "Why is it that almost every woman, as soon as she becomes a mother, begins to suffer from some pelvic disease?" but recur to the question, "How to procure the best possible physical condition after parturition?" If you can, make the woman's home life, social and moral surroundings as comfortable and free from worry as possible, saving and conserving her nervous system to the best extent attainable; pleasant exercise and attention to all the *diseases of gestation*; and, if possible, empty bladder and rectum before labor. Stay by her faithfully and attend to her judiciously during labor, letting ergot alone unless most positively indicated.

When the head, shoulders, and body are being born, with the left hand steadily compress the womb, following it up closely, so that when empty of child it will be firmly contracted on placenta. In fifteen minutes remove placenta by combined expression and tension on cord. Support perineum when needed, and bandage limbs in minor laceration, and operate on larger ones at once. Of course, it is expected of every accoucheur that hands, instruments, and everything about him will be clean and disinfected, as also about the patient. Apply forceps when necessary. *Leave the woman in a dry bed* with a good, intelligent nurse, with strict injunctions about diet, changing clothes, and attending to the breasts. Use the vaginal syringe only when indicated and not as a routine practice. Have the labia, outside and in, bathed three times a day with a solution of carbolic acid and water. Have the moral and social atmosphere as pure as possible; relieve pain. If in a malarial climate give quinine during the two weeks subsequent to labor. I consider this extremely important. Procure sleep, and *recognize deeply all the physiological processes which nature will set in play*. Keep her in bed fourteen days until the relaxed uterine ligaments gain strength and the weight of the womb is reduced, and last, but by all means not least, *let the lochial discharge severely alone, and let no interference be allowed except there is evidence that the proper involution is not taking place*, and the symptoms admonish us that there has been a laceration, and even then surgical interference will not be necessary in more than one-half the cases. It has become too much the fashion to go to extremes in turning up every parturient woman to a glaring light and taking a bird's-eye view of her genital canal, feeling assured that there is a "nigger in the wood-pile" that must be castigated, and in the relaxed, contused, swollen, and bloody passage finding something nature is incapable of taking care of under sensible and hygienic conditions, and trying to prove that nature in child-bearing women is, and has been, making grand mistakes every time a child has been born into the world. Let common sense, tempered and pruned by conscientious study and experience, following the guide-boards, indications, be the dictator. Let us recollect that no man has any right to disturb any *physiological process of nature in regard to labor*, lest he cause a blight to fall upon a home which will cause it to be darkened forever by the death of one of the most sacred and important individuals of the household—the mother. Following out the plan laid down, except in those cases of unavoidably bad labors from some dystocia due to mother, child, or secundines, we believe the results following will be the answer to the question propounded at the head of this article.

THE VARIOUS NEW YORK MEDICAL SOCIETIES have ceased to hold meetings until after the vacation. The larger number will commence work during the first fortnight in September.

TRACHEOTOMY: A REPORT OF TEN CASES, WITH REMARKS UPON THE INDICATIONS FOR THE OPERATION.

By NATHAN JACOBSON, M.D.,

SYRACUSE, N. Y.

I SHALL briefly present the records of my first ten tracheotomies, and purpose dwelling in their consideration upon the train of symptoms which necessitated the operation, and the circumstances affecting the prognosis or influencing the termination of the case.

CASE I.—During the months of June, July, and August, 1880, A. K—, a lad, ten years of age, was under treatment for a suspicious form of laryngeal and bronchial trouble. When first seen he had aphonia. He breathed with difficulty, each respiration being audible, the air producing a rattling noise as it forced itself through the accumulated mucus. He was emaciated, had a cough and night-sweats. No dulness upon percussion, mucous and subcrepitant râles could be heard over either lung. The epiglottis was ulcerated and cedematous; the upper part of the larynx swollen and filled with mucus. Slight glandular swellings about the neck. No fever. No Hutchinsonian teeth. No history of syphilis could at this time be revealed.

Upon cod-liver oil, hypophosphites and strychnia, and local applications of iodoform to the larynx during the succeeding months, his weight increased, his cough left him, the breathing was more free and the night-sweats disappeared, although the pulmonary condition had not materially changed. But during the rainy weather of August he took cold.

August 28th.—The pulse was rapid and feeble; temperature, 104° F.; dyspnea very severe, suprasternal and epigastric depression with each inspiration. Extreme cedema of the epiglottis and upper portion of the larynx existed. Emetics and hot fomentations failed to relieve the distressed breathing. On the following day, the trouble seeming rather aggravated than improved, tracheotomy was performed. Drs. Didama and Totman assisting. In the after-treatment no steam was used; the temperature of the room was maintained at about 80° F. The child remained under the constant care of physicians for forty-eight hours and then was transferred to the parents. The temperature by midnight of the day of operation fell to 99.5°. The following day it was normal, and remained so. On the third day after operation auscultation failed to detect any abnormal respiratory sounds. Anti-syphilitic and tonic treatment was pursued, with the local application of iodoform and astringents to the larynx.

A steady improvement was noted in the after-history of the case.

January 16th, four and one-half months after operation, the tube was removed. The wound healed nicely. There was complete freedom from dyspnea; the lungs were normal; the epiglottis cicatrized. A thickened condition of the mucous membrane of the upper part of the larynx remained; the voice was hoarse.

CASE II.—On the evening of May 30, 1881, I saw Anna H—, aged eight years. She was suffering from the ordinary symptoms of croup. Pharynx healthy. Temperature, 99.5° F. Emetics were prescribed and afforded great relief. On the following day she continued to be hoarse, yet her breathing was free. At this time the laryngoscope detected a fine film upon either false vocal cord, and reaching upward to the aryepiglottic folds. For the succeeding days the case was closely watched. The temperature never reached above 100° F. The breathing gradually grew more distressed, the attacks of dyspnea more severe and frequent, and the hoarseness developed into aphonia. Emetics, slaking lime, steam, and other remedies failed to relieve her. Doctors Pease and Plant were called in consultation to consider the necessity of doing tracheotomy. The operation was performed. For ten days succeeding the operation the temperature continued elevated, varying

from 100° to 102° . A diphtheritic deposit appeared upon the edges of the wound on the fifth day after operation. An erythema existed over the entire body during the second week. The urine was at all times free from albumen. Lime was freely slaked for several days, but seemed to irritate the bronchial tubes. One drop of liquor potassæ in an ounce of lime-water was substituted, sprayed by the atomizer over the mouth of the canula. This would always relieve impending dyspnoea due to accumulated mucus or loose membranes. For two weeks the child could not breathe, when the orifice of the canula was closed by the finger. During the third week air gradually found its way into the lung by the side of the tube. The patient was carefully watched day and night. On the twenty-fifth of June, twenty-two days after operation, the tube was removed.

CASE III.—On January 30, 1882, at 10 A.M., I was called to a child fourteen months old. The family lived in the fourth story of a tenement block, in very destitute circumstances. The child had been sick since the 28th inst. It was very hoarse, had great difficulty in breathing, and a temperature of 100° F. The tonsils were covered with a diphtheritic deposit, the glands of the neck badly swollen. A tent was made with a sheet and lime slaked. During that day and night it constantly grew worse. On the following morning, assisted by Drs. Aberdein and Totman, I did tracheotomy. The trachea was so small that, when the forceps were stretching it, the tube had to be introduced by main force. I could fairly feel the trachea tear under the pressure exerted. Dr. Cowles (who has since met a sad fate at Rochester) and myself in turn remained constantly with the child after the operation, and persisted in freely slaking lime. At eight in the evening diarrhoea appeared, and vomiting soon set in. The breathing remained free, the distress was perfectly relieved. The diarrhoea and vomiting became uncontrollable; the temperature rose to 103° in the evening, 104° during the night, and 105° in the morning. Convulsive twitchings appeared. At three in the afternoon, twenty-eight hours after operation, the child died in a severe convulsion.

CASE IV.—On the evening of July 19, 1882, Dr. A. C. Benedict requested me to see a child affected with membranous croup. I found a girl, seventeen months old, suffering from great dyspnoea. The family was living in some miserably ventilated upper rooms in a tenement house. The child was poorly nourished; had no pharyngeal patches. In an adjoining room was the mother, bedridden with phthisis. I urged that a tent be made and lime slaked. At the morning visit the father insisted that the lime had only helped to make the child worse. Three or four times he had placed the child upon the bed thinking it was dying. The condition certainly was worse, and Drs. Benedict and Totman concurred with me in the belief that unless tracheotomy be performed at once the child would die in a very short time.

There was some little difficulty in introducing the tube, because of the small size of the trachea. For several days some of our medical students watched day and night with the child, after this she was entrusted to the care of the father or willing friends. No case could have had more to contend with in the way of poor nursing, throughout the greater part of its history, than this one. The slaking of lime was discontinued and a solution of one drop of liquor potassæ to an ounce of lime-water sprayed over the mouth of the canula. This would always relieve her dyspnoea. On March 14th an effort to remove the tube was made. Dyspnoea returned at once and the tube had to be replaced. On April 3d the mother died, and, despite the inclement weather, the child was removed in a closed carriage to St. Joseph's hospital. Each month an attempt was made to remove the tube, but as often as it was withdrawn, whether under ether or not, the impending dyspnoea forced its return. The child would talk aloud, utter loud sounds, and apparently breathe freely when the finger was held over the opening of the tube,

yet it was never possible to remove it. The child's general health seemed fairly good. She played about, went out of doors, and was finally removed to Rochester, after having been in the hospital nearly four months.

CASE V.—W. A. S.—, aged fifty-four, a farmer residing in Otiseo, consulted me May 16, 1882. He had aphonia and some difficulty of breathing, which he attributed to a cold. There was a slight scaly eruption, perhaps half an inch square, on the upper lip, but no other cutaneous disease. His pharynx was healthy, but the larynx bore the unquestionable marks of syphilis. I prescribed anti-syphilitic treatment. Returning to my office on the afternoon of June 11th, I found the same person. He was laboring fearfully for breath, was cyanotic, had cold extremities and a very weak pulse. Dr. Munson had seen him in the morning and, recognizing the danger of the case, had sent him to the city to have tracheotomy performed. He was at once removed to St. Joseph's Hospital and etherized. Assisted by Drs. Totman, A. C. Mercer, and Stanton, I operated. Immediate relief was given. Stimulants and sustaining food, large doses of the iodide, a warm room but no steam, were prescribed. After three weeks he left the hospital for home, not a single unfavorable symptom had occurred. The tube, which might have been removed, was left in the trachea to give the larynx proper rest, that it might heal. He labored upon his farm, doing more work than he had in some time. Late in the summer, I am told, he was attacked with gastro-enteritis and died.

CASE VI.—On July 8, 1882, I saw—with Dr. Skinner, of East Syracuse—a child sixteen months old, well-nourished, slightly cyanotic, with hurried respiration and no fever. The child had been seen to put a bean into its mouth two days prior. It strangled, nearly suffocated, and finally, while the parents and friends were working over it, the foreign body was pushed downward. Drs. Skinner and Chase were called. It was impossible to dislodge the bean by emetics, position, or any means resorted to. The fact that the right lung was collapsed and received no air whatever, while all the respiratory sounds were exaggerated on the left side, indicated an impacted right bronchus. Tracheotomy was done, Dr. Skinner assisting. The dissection was very carefully and slowly made. The veins were crowded aside, the trachea finally exposed and opened for about half an inch. The tracheal orifice was held open by Dr. Skinner with a two-bladed dilator. After using half a dozen different forceps in vain, one devised by Stoerk, of Vienna, finally succeeded in grasping a piece of the skin of the bean. Soon another piece of the skin, then half of the bean and finally the remaining half. The wound was closed with straps. On the day after the operation the temperature was 103.5° , respiration 60, and pulse very rapid. The child was very restless and could not sleep, the straps had given way, and the child breathed through the tracheal orifice. Purgative, quinine, and sponging were prescribed. The next day the temperature had reached 104.2° , and no improvement in the other symptoms. The child breathed equally well with both lungs. On the third day the symptoms improved, and by the fifth day all fever disappeared. Five days later the wound had healed and the child fully recovered.

CASE VII.—At noon of October 9, 1882, Dr. Didama requested me to tracheotomize a child five years old, that he had just seen in consultation with Dr. Weaver. I found the child all but dead, with all the terrible symptoms of membranous croup. The little one was chloroformed, and the operation done. It seemed as if it could hardly live through the operation. Drs. Weaver, Totman, and Heffron were present. For two days the child was most carefully watched, with either a physician or a medical student in attendance. The laryngeal distress was completely relieved, but the respiration remained hurried and superficial and at times dyspnoea appeared. The alkaline spray was used, but did not relieve the dyspnoeic attacks as it had in previous cases. The

lungs were found to be œdematous. The heart's action continued very feeble, and stimulants were freely administered. The temperature never rose above 102° , but the lungs continued to grow more and more œdematous, the heart weaker, and finally, on the morning of the 11th, forty hours after operation, the little one died, not of suffocation nor in that terrible distress in which it was before operation, but because of the condition of the lungs.

CASE VIII.—October 22, 1882, at 1 P.M., I saw the child of M. S.—, three years old. The dyspnea was frightful, supra-sternal and epigastric depression marked, cold extremities, and the child dying for want of air. The pharynx was loaded with diphtheritic deposit, the glands of the neck swollen, the pulse weak, and the temperature 103° F. A physician had seen the child at his office on the previous day, and had promised to see the patient on the next, but failed to do so. Tracheotomy was performed, Dr. Totman assisting. The dyspnea was relieved. During the afternoon the temperature gradually increased, despite everything that was done, and at 7 P.M. had reached 106° F. The pulse became so rapid that it could not be counted. The child remained stupid during the entire afternoon, as if prostrated by the general infection. It died evidently of paralysis of the heart.

CASE IX.—About three o'clock on the morning of November 14, 1882, Dr. Oberlander aroused me and requested that I call with him upon a child, seven years of age, suffering with diphtheria. The tonsils and posterior arches of the pharynx were covered with membrane. There was every symptom of extensive laryngeal disturbance, which with the laryngoscope could be seen to be of the same character. It seemed as if the child must die at every moment. The parents consenting, tracheotomy was performed, the father holding a miserable oil lamp, the only source of illumination. An effort was made to chloroform the girl, but instead of relieving the distressed breathing, as it usually does, it tended only to aggravate it. You seemed to be between Scylla and Charybdis, death from chloroform or asphyxia from laryngeal obstruction. The tube was finally entered, the child breathed freely for about a minute, when respiration suddenly ceased and the child was dead.

CASE X.—Dr. Thomas, of East Syracuse, telephoned me about noon of April 2, 1883, to come to that village to see R. A.—, a child two years of age, that had been afflicted with pharyngeal diphtheria for several days. Three days prior to my visit the larynx had become involved. The dyspnea was very great. Tracheotomy was performed at 2 P.M., Drs. Thomas, Skinner, and Chase assisting. The child at once breathed easily, and for the first twenty-eight hours everything progressed fairly well. Twenty-four hours after operation I saw the child again. There was no laryngeal distress, the temperature had risen to 104° ; pulse, 150; respiration, 50. During the afternoon of the second day a very peculiar train of symptoms appeared. The respirations were not very labored, but would at times be very irregular, now rapid, and in a moment so slow that one would think the child had stopped breathing. These attacks would last perhaps fifteen minutes, when, for a time, the respirations would be regular. The temperature was very high; at 2 P.M., 105° ; at 3 P.M., $104\frac{3}{4}^{\circ}$; at 4 P.M., $105\frac{1}{2}^{\circ}$; at 5 P.M., 104.9° ; at 6 P.M., $105\frac{1}{2}^{\circ}$; at 7 P.M., $104\frac{1}{2}^{\circ}$; at 8 P.M., 103.5° . For the reduction of the heat, quinine, sponging, and the cold pack were used. The temperature of the room was kept at 80° . Vessels with steaming water kept the atmosphere moist. The alkaline spray was used. At midnight I was sent for. Dr. Thomas had been in attendance the entire evening. The child had several of the severe attacks of breathing described. At one time it was thought to be dying of collapse, but brandy hypodermically revived it. At midnight, pulse, 160; respiration, 48; temperature, 99.5° , and the child was sleeping quietly. In this condition it remained until 1.30 A.M., when the respirations suddenly increased to

70 and became very shallow. This continued about a minute when the jaws became firmly set, the extremities cold, and the respirations reduced to ten per minute. The pulse gradually became slower and slower, until it reached ninety. Stimulants were given hypodermically as rapidly as possible. Suddenly the child ceased breathing. The heart continued to beat for about a half minute after the breathing had ceased.

Remarks.—The questions now arise: When is tracheotomy indicated? What hope does it afford? What difficulties does it present? What benefit, in reality, is derived therefrom? In the cases here reported the operation was done for immediate relief from impending suffocation, save in the instance where the foreign body was removed from the bronchus. In each case it was the unanimous opinion of the physicians in attendance that without the relief the operation would afford death must follow, and, in many of the cases, that very soon. In each case emetics, lime, steam, or some other favorite mode of treatment, had been thoroughly tried, but without any resulting benefit. In all the same tale is told of increasing distress in breathing, approaching cyanosis, more frequent attacks of dyspnea; shorter intervals of free breathing; labored respiration, with supra-sternal and epigastric depression with each respiration; cold extremities; a pale, anxious countenance; strength exhausted, and the patient dying. Allowed to progress, the patient grows more and more cyanotic, the heart weaker, the lungs œdematous, the breathing more labored, indeed, frightful to behold, and when death comes it is thankfully received, for it frees the patient from terrible agony. Tracheotomy opens the way for supplying the much-needed air to the lungs. The blood is again aerated, cyanosis disappears, the breathing is easy and tranquil, and the extremities regain their warmth. The patient is given an opportunity to outlive the disease. The operation is only done when we feel certain that no other course is left open from which we may expect favorable results. But what encouragement does the operation offer? Let us study the successful cases and see. Of the five that ended in recovery, two were done for syphilitic laryngitis, one for the removal of a foreign body in the bronchus, and two for membranous or diphtheritic croup. In the first case (the child with hereditary syphilis) we gained not only immediate relief from severe dyspnea but a restoration of the lungs to a healthy state; rest for the larynx, and finally a permanent recovery from the laryngeal disease. Fully as much was secured in the other case of syphilitic laryngitis; although when found at my office he was so nearly dead that it did not seem possible that he could survive until conveyed to the hospital. He was so thoroughly unconscious that when he grew better he was unable to recall anything that transpired for two hours prior to the operation.

The case of foreign body in the air-passages is no less instructive. It certainly establishes the fact that an operation of the severity of tracheotomy can be successfully performed, and followed by an equally severe operation of entering the bronchus and removing the foreign substance, in a child but sixteen months old. It has been said that tracheotomy is unsuccessful in children under two years of age. This case, added to the other reported in this paper, and the many others in which our literature abounds, must disprove this view.

The two successful cases of membranous or diphtheritic croup will, perhaps, interest us more. The first, a girl of eight, asphyxiated because of laryngeal obstruction, made a good recovery without any complication, except the appearance of the diphtheritic erythema. The tube was removed three weeks after operation. The wound healed nicely.

The second, as stated in the report, faced all the difficulties a case could contend with. But seventeen months old, a consumptive mother dying in the next room, a miserable home with the vilest and filthiest sur-

roundings, obliged to be cared for by the neighbors, and being transferred during cold and raw weather to the hospital, were obstacles enough. It is but fair to presume that if a child, under these circumstances, could recover when at the time of operation it hardly seemed possible that she could live through it, there must be hope for other children.

As to the unsuccessful cases. The first, a child but fourteen months old, with pharyngeal diphtheria, poorly nourished, poverty-stricken parents, and wretched hygienic surroundings, met its death through cholera infantum with high fever and convulsions.

The second was of good age and robust, but the operation had been too long delayed. (Edema of the lungs existed. The child was exhausted with vomiting and the labor of breathing with the existing dyspnoea. There is good reason to believe that had the operation been done earlier the child would have recovered. The third death was likewise after an operation performed when the child was almost breathing its last. But the terrible general infection and the high fever overpowered the child. The fourth affords an opportunity for argument. Whether chloroform occasioned the death or some hidden cause existed I cannot say.

In the last case, the child did nicely for twenty-four hours, but the peculiar respiration and the accompanying peculiarities of pulse and temperature point, in my mind, to some central disturbance as the cause of death.

In all cases the object for which tracheotomy was done was thoroughly accomplished. The patient was made to breathe freely. Now the question arises, What is the duty of the physician in this class of cases? When called to a case of diphtheritic or membranous croup, it should be his care to thoroughly enlighten the parents as to the character of the disease and what may develop. He should carefully watch its progress. If accumulating mucus in the larynx obstruct the passage of air, emetics may be administered to relieve it. But their persistent and continued use in cases where adherent membrane alone occludes the passage can only result in debilitating the child, while affording no relief to the dyspnoea. The use of the line should not be continued when it fails to afford relief or hold the disease in check. As will be observed I have had but poor results from its use. The physician is culpable if tracheotomy be long delayed, and resulting oedema of the lungs and a weak heart develop. The operation should not be done as a last resort after the ill-spent effects of turpeth mineral, sulphate of copper, alum, and the host of other emetics have exhausted the child. There is no reason why a case should be watched from day to day, continually growing worse, and then operated upon under the dim light of a miserable kerosene lamp, at an early hour in the morning, just as the child is ready to shuffle off its mortal coil.

We cannot even assure the parents that the child will live through the operation; but should it, we can safely promise that it will breathe freely. One thing is sure, they have nothing to lose, everything to gain by tracheotomy. Moreover, they should be given to understand the necessity of patient watching. The child must not be allowed to sit up, for fear of syncope, to turn its head, for fear of inducing suffocation. The tube must be cleaned at proper intervals. The temperature of the room must be cared for; a moist atmosphere produced. Weeks, perhaps months may pass before the tube can be removed and the child breathe per viam naturalem.

These are the points that we must consider in asking ourselves what can we expect from, what can we promise for tracheotomy.

THE LAW AND THE DOCTOR.—Dr. McLean, of Ann Arbor, Mich., has been successful in his action for libel against the *Detroit Evening News*. He has recovered damages to the amount of \$20,000.

Progress of Medical Science.

OXYDENDRON IN ANASARCA.—Dr. Clendenin (*Therapeutic Gazette*, April, 1883) calls attention to a drug which the eclectics have had good success with in the treatment of dropsy. The drug in question is sourwood (oxydendron), which grows abundantly throughout the Southern States. The leaves and bark of the sourwood contain the medicinal properties, being diuretic and laxative. The best way to use it is to make a semi-solid extract, which should be worked into two grain pills, to be given in doses of two or three pills, three times daily, gradually increasing the dose each day until twelve or fifteen pills are given during the day, then gradually decreased day by day until the original dose is reached. By this mode of treatment he claims dropsical effusions of the worst form may be often removed.

SUBACUTE DIFFUSE SARCOMA OF THE PERITONEUM.—The following case is reported by Dr. E. Gaucher in *La France Médicale* of March 31, 1883: A young man, twenty-seven years of age, had been suffering for two months with obstinate diarrhoea, the stools at times being mixed with blood. He emaciated rapidly and lost strength. About a week before admission to hospital his abdomen began to increase rapidly in size and his legs became cedematous. The belly was hard and tense and very painful on pressure. There was excessive tympanites with but moderate ascites. The latter, however, increased rapidly after a few days, and so interfered with respiration that it became necessary to perform paracentesis. About twenty-five ounces of sanguineous fluid was taken away. The patient appeared to be relieved by the operation, but died three hours later. At the autopsy the peritoneum was found to be thickly studded, throughout its whole extent, with very vascular cancerous vegetations resembling raspberries. The omentum presented a most peculiar appearance, entirely covered, as it was, with these raspberry vegetations, filled with blood and pressing closely one against the other. There were no cancerous lesions to be found in any of the viscera, nor was there any glandular infection. The vegetations were seen under the microscope to be composed of embryoplastic cells, closely pressed together, and sustained by a delicate network of fibrous connective tissue. There was a large number of newly formed blood-vessels.

NAPHTHALINE AS AN ANTISEPTIC.—In a monograph entitled *Die Wundbehandlung mit Naphtalin*, Dr. Carl Bonning has formulated the results of upward of fifty cases in which naphthaline dressings were employed after operations in the Strasbourg surgical clinic. From a study of these cases, as also of a number of other less serious injuries treated in the polyclinic, he feels justified in regarding this substance as a most valuable antiseptic. He sums up its advantages as follows: 1. It is very cheap—a consideration not to be despised, especially in hospital practice. 2. It is convenient to handle and easy of application: it is simply sprinkled in powder upon the wounded surfaces and the dressings, or cavities may be filled with it. 3. It is not poisonous, and thus may be used without fear in cases in which the employment of carbolic acid or iodoform might be attended with untoward consequences.

In a brochure on the same subject (*Naphtalin in der Heilkunde und in der Landwirthschaft*), Dr. Ernst Fischer speaks most highly of its destructive action upon the lower forms of animal and vegetable life. He advances the same considerations in its favor as does Dr. Bonning, viz.: its ease of application, its non-poisonous properties, and its cheapness. Among its disadvantages he recites: 1. Its insolubility in water, whereby it is unsuitable for the disinfection of wounds which are to be closed by suture. 2. Its disagreeable odor. 3. The pro-

fuse secretion which naphthaline excites where it is applied to a large extent of wounded surface. He recommends its use also in skin diseases of parasitic origin. The second part of the monograph is devoted to a consideration of the value of naphthaline in agriculture, and especially of its destructive action upon the phylloxera.

LAPPA MINOR IN PSORIASIS.—Dr. W. C. Reiter (*Squibb's Ephemeris*) claims that the use of a tincture of burdock seed has yielded excellent results in the treatment of psoriasis. The tincture is made from one part of burdock seed ground fine, and macerated with eight parts of diluted alcohol. The dose is a teaspoonful.

URIC ACID AND RENAL CONCRETIONS.—In the Lumen Lectures for 1883, Dr. Garrod (*British Medical Journal*, March and April, 1883) took for his text the physiology of uric acid and its relation to renal calculi and gravel.

Two theories, he said, as to the origin of uric acid in the animal economy are advanced. In the first, the kidney is regarded simply in the light of a strainer of the uric acid which is formed in the blood, and passes through it. In the second, the kidney is held to be the actual producer of uric acid, and the presence of this principle in the blood and tissues is explained by resorption from the renal cells, a process which becomes more marked in proportion to the difficulty which the uric acid has in finding its way to the uriniferous tubes.

The human subject excretes on an average in the twenty-four hours about one part of uric acid for each 120,000 parts of his weight, whilst in birds the amount excreted is about $\frac{1}{120}$ part of the body-weight. Again, the blood of the bird is as free as, and often freer than, that of man from uric acid, so that it is hardly possible to look at these facts and maintain the first theory that uric acid first exists in the blood.

Another point which goes to disprove the first theory is that in the kidney-cells uric acid exists combined with ammonia, but when found in the blood, or deposited in the tissues, either of man or the lower animals, it is in the form of urate of sodium. If the second view is adopted, and it is assumed that urate of ammonium is produced in the kidneys, and that it sometimes becomes resorbed into the blood after its formation, experiments show that urate of ammonium is readily converted into urate of sodium, if added to a solution containing a large excess of either phosphate or chloride of sodium. The presence of urate of sodium in the urine of man and the carnivorous mammal is explained by the fact that the urate of ammonium meets with large quantities both of phosphate and chloride of sodium, and thus becomes converted. Those who consider that uric acid is formed before it reaches the kidneys, generally fix upon the spleen as its source; and Dr. Michael Foster remarks in his work on physiology that the increase of uric acid during ague and during ordinary pyrexia seems to run parallel to the turgescence, and therefore, presumably, the activity of the spleen. As far as Dr. Garrod's experiments go he has, however, proved that the spleen of the turkey and common fowl is almost entirely free from uric acid, and that of the ox contains a good quantity, whereas the urine of the turkey or fowl contains much more uric acid than that of the ox. One fact is mentioned as regards the second theory, and that is—that the urine of the sucking calf and the young of other herbivora contains uric acid in notable quantities, while that of the adult animal is usually free from it, making it hard to reconcile the view that uric acid is formed in the kidneys.

Uric acid is the chief ingredient of human urine to which attention is directed, and it is shown: 1. That uric acid exists in the urine as urate of sodium, unless the urine is very ammoniacal; then the uric acid, meeting with a large excess of a new base, is deposited as urate of ammonium. 2. That uric acid is held in solution in an acid fluid solely on the tribasic character of

phosphoric acid, for with the urate of sodium is also formed the acid phosphate of sodium, which exhibits a full acid reaction, but does not possess the power of precipitating the uric acid. 3. That whenever any free acid exists in the urine, the uric acid is immediately precipitated. 4. That the different shapes which uric acid assumes when it is precipitated from its state of solution are, either in combination with a base, *i.e.*, in the form of a urate, or a free uric acid.

After demonstrating the action of carbonate of lithium on small calculi, and on the spherules from the urine of reptiles, Dr. Garrod draws attention to the influence of diet on the production of renal calculi, and assumes that whatever in the way of food tends to produce gout tends to develop calculus also. Special stress is laid on the effects of saccharine food and of different alcoholic beverages on the uric and excreting function, and an important point is noticed with regard to allowing patients a proper amount of animal food, as it does not tend to increase the amount of excretion of uric acid. With regard to the causes of gravel and calculi, Dr. Garrod's experience shows him that gouty subjects, or those who inherit that diathesis, are more liable than others to gravel and calculus. Portal congestion is another point to be looked at in the prophylactic treatment of gravel and calculus. Where there is a tendency to the rapid deposition of uric acid from the urine, the value of water as a therapeutic agent is shown. Speaking of the effects of alkaline treatment, the advantage of the lithia salts is discussed. Hippuric and benzoic acids in an alkaline solution possess the power of changing and removing uric acid, so that these salts should become valuable in the way of treatment, and great benefit has resulted from the use of benzoate of sodium in cases of gout and of gravel and calculus; and if you wish at the same time to increase the quantity of the urinary excretions, then give the benzoate of potassium or of lithium.

THE ORIGIN OF ARTICULAR INFLAMMATION.—Professor Schüller observes (*Deutsche Med. Wochenschrift*) that at the present day we do not think of inflammation except in connection with some special inflammatory excitant. Such exciting material may be chemical or organic, and may enter the joint in one of three ways: 1, through an external wound into the joint; 2, by the blood; 3, by spreading from the neighboring tissues. With respect to open wounds of joints, antiseptic surgery has taught us that they are not inevitably followed by purulent inflammation, as was formerly supposed, but only when some of the exciting causes of inflammation can enter the wound and develop in the joint. Inflammation in closed joints cannot be caused by contusion, unless there be an exciting cause of inflammation in the blood itself, or in some part of the body where it can pass easily into the circulation, and so reach the joint by means of the extravasation. Such a cause must be always present when inflammation of a joint results from a simple injury. Metastatic inflammation can take place in the joints without injury of any kind, as in acute rheumatism, pyæmia, etc.; and the exciting material may be micro-organisms, as in pyæmia, or a chemical substance, as in gout. The anatomical arrangement of the tissues of the joint probably predisposes to the deposition there. Lastly, inflammation may result when the excitants enter the joints from the neighboring tissues, which they may do suddenly, as in some forms of acute osteo-myelitis, gradually invade the articular tissue from point to point, as in syphilitic and tuberculous inflammations, or enter through the lymphatics, as in phlegmonous infiltration and some forms of acute infectious osteo-myelitis. Dr. Schüller finally points out how many of the old ideas on inflammation of the joints are again coming to the front, how great is the advance which we have made in the knowledge of the subject, but how much still remains to be done before we have a clear insight into the processes and causes of the inflammation.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 30, 1883.

COLLATERAL INNERVATION.

M. RICHELLOT has recently communicated to the Société de Chirurgie the report of a case which appears to indicate the possibilities of a collateral motor innervation developing when the normal nervous supply has been cut off. The patient, a young man twenty-six years old, had at the age of seven sustained a compound fracture of the right humerus just above the elbow. The bone healed, but the median nerve had been injured, and its integrity destroyed. There was, consequently, paralysis of the flexors of the fingers, of the outer lumbricales, and anesthesia of the palm of the hand, ball of the thumb, and first and second fingers. In the course of two years sensibility was gradually restored. Movement also returned to a considerable extent, the movements of the fingers being feeble but free. The muscles of the forearm and thenar eminence were considerably atrophied. The patient applied for relief from pains in the arm, caused presumably by a neuroma of the median nerve just above the elbow. The tumor was removed, and in doing so the median nerve was entirely severed. Curiously enough, motion and sensibility continued in the fingers nearly as before. The hypothesis suggested is that a collateral innervation, probably from the ulnar, had gradually developed. The phenomena of collateral innervation of sensory nerves has been often observed, but that of motor nerves is certainly rare. M. Verneuil reported a somewhat similar case, however.

BICYCLE RIDING.

It may be laid down as a rule, to which there are few exceptions, that an out-door sport which maintains for years a wide popularity is not essentially an injurious one. The average man is a tolerably sensible creature, and learns sooner or later whether a particular practice is hurting him or not. So it is that ball-playing, tennis, cricket, boating, all have, as a general result, the promotion of health. Some individuals are injured, as some individuals always will be, no matter what they do. But the criticisms directed against these various pastimes apply only to an over-indulgence in them.

The question as to the healthfulness of bicycle-riding has been much agitated of late. Some medical journals and medical men have asserted that the practice leads to all kinds of troubles: hernia, varicocele, sexual weakness, spermatorrhœa, and so on. This is a view which is unquestionably not true, so far as facts at present show.

There are certain individuals whom it may injure, and there is a certain number of accidents which must inevitably accompany locomotion on a somewhat unsteady vehicle. But bicycle-riding is not injurious to the mass of those who practise it. We do not consider it a model form of exercise. It brings into play chiefly the extensors of the foot, the flexors of the leg, and the abdominal muscles. The chest or arm-muscles are not greatly exercised, and there is, at times, some mental tension connected with the possibility of at any time taking a "header."

For all this, bicycle-riding is an excellent form of exercise, as well as an exhilarating mode of locomotion for many people. The propagation, by certain alarmists, of the view that it is going to spread the disease of the Scythians among us should be discountenanced.

THE MEDICAL VACATION SYSTEM.

Just now the fancy of the city physician lightly turns to thoughts of summer hotels and sea-side resorts. The exodus to these places appears to be greater every year, until in this particular city, in August the inhabitants have to depend chiefly upon the natural salubrity of the climate and counter-prescribing in their physical distresses.

Going out of the city, however, does not by any means signify that the doctor is taking a vacation. The custom is rapidly growing of taking up a summer practice, and it is one which often furnishes no small addition to the doctor's income. By a practice at a summer resort he enlarges his acquaintance and greatly multiplies his fees.

There are very few medical men who do not need all the money they can earn, and to some a vacation practice is almost a necessity. It is one that is not without abuses, however. The physicians at summer resorts have in too many cases developed remarkable business talents, and have shown a capacity for capturing patients and sending in bills which would adorn the memory of Captain Kidd or the lamented Jesse James much more than the members of a learned profession. In fact, the "hotel doctor" has been rendered a suspicious character in some quarters, and we fear justly so. It is certainly very much to be regretted that medical men should risk the dignity and honor of their profession for the sake of earning a few more dollars.

A new phase of the summer vacation system is gradually developing, and not in this city alone. It is the custom of letting other physicians know by card where one is to stay during the summer. The practice is, within proper limits, a good and useful one. It is the custom in Germany every spring, when the bath season sets in, for medical men to announce in the medical journals where they will practise during the summer. A summer medical directory might be a desirable thing for the city physicians of this country.

OUR DISPENSARIES.

ONE of the younger men attached to a large dispensary in this city, writes us as follows:

"DEAR SIR: A patient, a German liquor dealer, came to my class in the dispensary, a short time ago. After being treated a few times, he took out his pocket-book to

put in it some directions I had written. It was bulging out with bills so that he could hardly shut it. I wanted very much to exchange it with my own.

"An old lady comes to me wearing gold jewelry and a silk dress, and looking very much as though she had a large income. She wore such a benignly respectable air, however, that I didn't like to ask her whether she was a fraud or not.

"Two or three nicely dressed school-girls come to my class. Their parents can evidently afford to dress them nicely but wish to shirk their doctor's bills. It is, I believe, a very prevalent practice, and one that is extending, for the head of a family to send his wife and children to the dispensary. For a long time I treated the wife and child of a German engraver who earned (as I learned later) about \$80 amonth. But he would not give his family any money with which to pay for medical services.

"I wish that something could be done for these cases. It makes a good deal of dispensary charity seem like a humbug, and it seems rather hard on the doctors.

"Very truly yours, M. S."

Our correspondent has touched upon an old theme and an old abuse. The suggestion that the paterfamilias who holds the purse-strings is getting into the habit of sending his family to the dispensaries deserves consideration. We would call the attention of our correspondent, as well as of all connected with dispensaries, to the fact that a partial remedy at least for the abuse described is at hand. The Charity Organization Society has undertaken to investigate all suspicious cases that are reported to them. If a little pains were taken to send to the Secretary of this society every week or oftener, a list of patients suspected of being able to pay, a great deal could be done.

It would not take a long time to create the impression that dispensaries were only for those who can not pay. In fact, with the opportunities which we understand are now offered, it is largely the doctor's fault if he continues to treat gratis those who can afford to pay him.

NEUROLOGY AND THE AMERICAN NEUROLOGICAL ASSOCIATION.

THE meeting of the American Neurological Association, which took place in this city last week, is said to have been one of unusual interest, scientifically and socially. Representatives from Chicago, Philadelphia, Baltimore, Boston, and other cities, were present. The President, Dr. Hammond, in his retiring address, referred to the continually increasing prosperity of the society, but expressed some surprise that a specialty so broad and comprehensive as neurology should not excite a still greater interest than it had done. The explanation suggested was that nearly every practising physician felt himself to be more or less of a neurologist. However this may be, it is no doubt a fact that less special attention is paid to nervous diseases by medical students and by practitioners than to many other much narrower branches of medicine. Clinics for nervous diseases are but poorly attended unless the lecturer has some special popularity. And even in some large colleges a general practitioner is thought quite capable of lecturing on neurology. This indifference is to be deprecated, since a sound knowledge

of the nervous system in health and disease is indispensable to a correct and rational method of practice.

The American Neurological Association is doing something toward exciting a wider interest in its important department.

News of the Week.

THE DEATH OF DR. MORITZ MICHAELIS, of this city, occurred on June 23d. Dr. Michaelis was born at Detmold, Germany, in 1811, and came to New York in 1840. He was well known for his obstetrical skill, kindly disposition, and unostentatious charities.

UNITED STATES SANITARY INSPECTOR AT HAVANA.—Dr. Daniel M. Burgess has been reappointed Sanitary Inspector for the United States at Havana. Dr. Burgess will act under the direction of the United States Marine Hospital Service and the immediate direction of the American Consul-General for the sanitary inspection of vessels bound for the United States.

A REJECTED CANDIDATE.—A woman physician recently made application for admission to the Onondaga County Medical Society, at Syracuse. She was rejected by a vote of thirteen to six. It was stated that she had advertised in the daily papers.

CONCERNING MEDICAL DEGREES IN GREAT BRITAIN.—Our London correspondent calls our attention to the fact that *not* is omitted in the last sentence but two, second column, page 614. It should read: "The L.R.C.P. is *not* a physician's diploma."

THE TYPHUS CASES FROM ST. STEPHEN'S HOME.—The children attacked with typhus fever at St. Stephen's Home and removed to Riverside Hospital, have nearly all recovered, a few only of the recent cases being still under treatment. The fever appeared in only one of the houses belonging to the Home, and the number of cases thus far occurring is twenty-four. With a view to thoroughly eradicate the infection it has been determined by the Health Department that the children exposed to the fever be removed to North Brothers Island for quarantine and observation, and the house in the meantime be renovated. For this purpose the old hospital building on the island has been put in order, and early last week the children were transferred to their new temporary quarters, where they will enjoy a few weeks of fresh air. One of the trained nurses at Riverside Hospital has been very sick with typhus contracted from the children under her care, but is now convalescent. This is the third one of the regular nurses that has taken the fever since its recent advent among us.

THE PROGRESS OF THE TUBERCLE WAR.—The acerbity of Koch's criticisms of his Vienna critics has stimulated them to a remarkable activity in the study of tubercle bacilli. At a meeting of the Vienna Society of Physicians, May 11th, Professor Stricker and Dr. Spina reported further results. They reaffirmed the opinion that the tubercle bacilli, so-called, were not characterized by a peculiar staining which other bacilli did not take. They asserted that this bacillus could not be considered a special form, morphologically or chemically, of micro-

organism, and further, they asserted that they had produced tuberculosis in perfectly healthy guinea-pigs by injecting particles of glass and cinnabar. It is expected that a commission will be appointed by the Society to settle the whole question.

UNINTERRUPTED SERVICE.—In the surgical division of the Roosevelt Hospital, the plan of having an uninterrupted service, which has been on trial during the past year, has received the approval of the Board of Trustees, who, at a recent meeting, reappointed Dr. Henry B. Sands as the sole attending surgeon, to serve during the pleasure of the Board. Dr. Wm. S. Halsted was reappointed in a similar manner, as Dr. Sands' assistant, and was also placed in charge of the out-door surgical department, which, with an out-door medical department, under the direction of Dr. J. West Roosevelt, has just been established. The hospital contains seventy-five surgical beds.

AN INTERNATIONAL CONGRESS FOR THE PROTECTION OF INFANTS was opened in Paris on June 15th. It is held under the auspices of the Society for the Protection of Abandoned Infants.

IODOFORM AS A VERMIFUGE.—Dr. Schildowsky finds that iodoform is an excellent remedy for nematoid worms. He gives it in doses of one grain to adults.

DEATH OF PROFESSOR VALENTIN.—One of the Nestors of Physiology, Professor Valentin, of Berne, Switzerland, died on May 25th, in the seventy-third year of his age.

DR. JOHN SWINBURNE has been elected mayor of Albany.

THE LATE DR. WILBUR'S SUCCESSOR.—Dr. G. A. Doren, of Columbus, O., has been elected Superintendent of the New York State Asylum for Idiots.

BANQUET IN HONOR OF M. VILLEMIN.—A banquet was tendered on May 26th, by a number of eminent Parisian medical men, to Professor Villemin, of Val-de-Grâce. It was rightly considered very appropriate that now, when the infectiousness of tuberculosis is so universally conceded, that M. Villemin, who first experimentally demonstrated the fact, should be remembered. It was on March 6, 1865, Villemin inoculated a rabbit with particles from a phthisical lung. The animal subsequently died of phthisis.

KRAO, THE MISSING LINK.—There is now on exhibition at the Westminster Aquarium, London, a girl seven years old, who presents many striking simian characters. Her body is covered with hair, her face is very prognathous. Her feet are prehensile, and she can pick up even small objects from the floor. She comes from Laos, in the interior of Indo-China, and her parents are both covered with hair. She can speak some words of English. A full account of her is given in the *Revue d'Anthropologie*.

DR. W. H. DUKEMAN, of Olean, N. Y., is the author of the article on "Impermeable Stricture of the Urethra," in our last issue, instead of Dr. W. H. Dikeman, as printed.

THE COLLEGE OF MIDWIFERY OF NEW YORK.—At the completion of the first annual course in this institution nine candidates presented themselves for examination. Of these, seven passed very creditably and two were rejected. The following are the names of the grad-

uates in the order of their merit: Katie E. Vanderbilt, Marie Mount, Annetta Meyer, Kathrine Mergel, Bridget A. Mullady, Rosina Stuhlfauth, Theresa Hall. The standard of requirements for midwives is high, the examinations are impartially made by a board of censors, and the school is destined to be a success.

THE ELECTION OF THEOPHILUS PARVIN AS PROFESSOR OF OBSTETRICS IN JEFFERSON MEDICAL COLLEGE.—The Trustees of Jefferson Medical College, Philadelphia, elected, at their meeting held June 25th, Professor Theophilus Parvin, of Indianapolis, successor to Professor Ellerslie Wallace in the chair of Obstetrics. This is one of the best appointments that could have been made. We congratulate the college on securing the valuable services of this distinguished and successful teacher, and predict for him a brilliant future in his new career of usefulness.

A POLYCLINICAL DINNER.—The Faculty of the New York Polyclinic gave a dinner at Delmonico's to the assistant clinical staff, on June 23d.

FLOATING HOSPITALS.—The German admiralty, says *Gaillard's Medical Journal*, are going to try a novel experiment, as they intend to send a complete hospital ship to accompany the Baltic squadron on its evolutionary cruise. A corvette has been fitted with cots, requisites for the sick and wounded, instruments, and operating tables. It is intended that in any future war the vessel shall accompany the fleet into action, carrying the Geneva flag; and, in order further to distinguish her, she has been painted white with a red streak.

A DRUGGIST SENTENCED FOR SELLING TOO MUCH MORPHINE.—A Parisian druggist has been sentenced to eight days' imprisonment and a fine of twenty-one hundred francs for selling four hundred dollars' worth of morphine in the space of ten months to one of his customers.

A GERMAN-AMERICAN MEDICAL MONTHLY.—The *Medicinish-Chirurgisches Correspondenz-Blatt* is the title of a new monthly intended for German-American physicians. There are over two thousand of these in the country, and it is thought that they need an organ. The journal is published in Buffalo, N. Y., and edited by Dr. M. Hartwig, of Buffalo, in conjunction with Dr. Meisburger, of the same city; Dr. Jacobson, of Syracuse; Dr. Proegler, of Fort Wayne, Ind.; Dr. Schwartz, of Vienna; and Dr. Reuter, of Berlin. In an editorial note, commenting on the Code controversy, the editor says: "The physicians in Germany have never felt the need of a Code, and have never had one. The general rules for guiding the conduct of gentlemen have been found sufficient." It naturally appears strange to foreign eyes that American physicians alone are the only ones throughout the world who seem to think that they need a written Code.

ECLECTICISM IN MICHIGAN.—We are informed by the *Eclectic Medical Journal*, that a bill to establish a department of eclectic medicine in the University of Michigan has been introduced in the Legislature of that State. Should it pass, the unique spectacle would be presented of the three systems of medicine—regular, homeopathic, and eclectic—being taught in one and the same institution.

Reports of Societies.

THE AMERICAN NEUROLOGICAL ASSOCIATION.

Ninth Annual Meeting, held in New York, June 20, 21, 22, 1883.

WEDNESDAY, JUNE 20TH—FIRST DAY—AFTERNOON SESSION.

THE American Neurological Association convened in the hall of the New York Academy of Medicine, and was called to order at 2.30 P.M., by DR. WILLIAM A. HAMMOND, of New York, the retiring President, who made a few appropriate remarks, and then introduced the President-elect, Dr. R. T. Edes, of Boston.

Dr. R. W. Amidon, of New York, was elected Secretary, *pro tem*.

THE PRESIDENT'S ADDRESS.

DR. EDES said that if he were called upon to select a single word that would best express the progress made in neurology during the last few years, that word would be "localization." Although we see where the blow has struck, it is worth while to consider how important is the knowledge which is so greatly lacking, or so merely speculative as to its nature and origin, and how essential it is that correct views should prevail as to early symptoms. Two opposite views prevail, in two classes of minds, as to the significance of symptoms which have not become thoroughly declared. One set of men, who may be found especially among the therapeutists, are prone to consider every recovery after symptoms which are more or less allied to those that point to the serious organic diseases as cures, and such they may be in some cases. The error consists, not in recognizing the beneficial effects of treatment, but in not considering that disorders which are at the beginning functional, or hardly more than such, may turn toward recovery or toward organic lesions. The other error is that of the anatomist, who looks at all diseases in the light thrown backward from the autopsy, and who is apt to think of lesions as existing from the beginning, and regard failure in therapeutics as a mistake in diagnosis. But both classes of minds are necessary to the progress of neurology, as for other branches of medicine, and both require for their correction that most important piece of apparatus, without which no physiological laboratory is complete, no matter how elaborate its other furnishing is, that vulgarly known as the "level head." One of the first thoughts in all our minds must be the losses which the meeting of the Association had sustained in the absence of the Secretary, who had done so much of the scientific work, and in the death of one with whom many often differed, but whose laborious investigations and suggestive writings had added so much to our interest and instruction.

In conclusion, Dr. Edes read a letter from Dr. Seguin, dated Zurich, Switzerland, May 30, 1883, in which he expressed the unabated interest he retained in the welfare of the Association, and sent a friendly greeting to the members, from whom, without exception, he recalled only courteous and friendly acts.

The Council reported that they had examined the papers presented by the following candidates, and recommended that they should be elected to membership in the Association: Drs. Leonard Weber, of New York; G. L. Walton of Boston; and J. T. Eskridge, of Philadelphia. These gentlemen were unanimously elected.

NOMINATION OF CANDIDATES.

Dr. Ralph L. Parsons, of Sing Sing, N. Y., and Dr. Charles F. Folsom, of Boston, were nominated for active membership.

NOMINATION OF OFFICERS.

Dr. Isaac Ott, of Easton, Pa., and Dr. Landon C. Gray, of Brooklyn, were nominated for *President*. Dr. Ott was elected.

Dr. W. R. Birdsall, of New York, and Dr. J. J. Putnam, of Boston, were nominated for *Vice-President*, and Dr. Birdsall was elected.

Dr. R. W. Amidon, of New York, and Dr. E. C. Seguin, were nominated for *Secretary* and *Treasurer*. Dr. Amidon was elected.

Drs. J. J. Putnam, of Boston, V. P. Gibney, F. P. Kinnicutt, and W. J. Morton, of New York, were nominated for *Councillors*. Drs. Gibney and Morton were elected.

DR. CHARLES L. DANA, of New York, moved that the President appoint a committee of two to prepare suitable resolutions with regard to the death of Dr. George M. Beard. The President appointed Dr. C. L. Dana and Dr. C. K. Mills, and suggested that the committee prepare a letter to be entered upon the minutes, instead of the usual resolutions.

Dr. W. J. MORTON, of New York then read a paper on

NEURITIS FOLLOWING DISLOCATION.

The paper constituted a contribution to traumatic neuritis, and was illustrated by a case following dislocation of the humerus. The essential features were the following: Injury to the brachial plexus, motor paralysis, sensory disturbance (exaggeration of tactile sense, hyperalgesia, diminished temperature sense), reaction of degeneration, cedema, glossy skin, painful joints, causalgia, fibrous hyperplasia, neuro-muscular hyper-excitability, extension of disturbance to opposite member; that is, ascending neuritis.

The patient, Alexander M—, sixty-five years of age, about ten months ago slipped on the sidewalk and fell, striking on his right shoulder. His arm was rendered nearly motionless, the shoulder painful, and soon the hand and forearm swelled. He went to Bellevue Hospital, had his shoulder set, and remained there two days. From the hospital records the following note was taken: "Admitted September 27, 1882; diagnosis, alcoholism and dislocation of the humerus; discharged September 29th." The record was important only as establishing the fact that dislocation existed.

An interesting feature in the case was the fact that the left, or opposite arm, at the end of ten months, showed evidence of being affected by the injury originally inflicted upon the right axillary plexus. Electrical changes were present, which approach to the reaction of degeneration so prominent in the right arm; but more curiously, neuro-muscular hyper-excitability was also present, although in a modified form.

Two noteworthy symptoms were noticed. First, fibrous hyperplasia. The usual nutritive disturbance following neuritis is atrophy of various tissues. Dr. Morton had found only one such case, that reported by Weir-Mitchell, and his case formed a fitting companion for it. As regards the hyperplasia, it ranks with Mitchell's as a unique observation.

Second, neuro-muscular hyper-excitability. If we would find an exact parallel we must turn to Charcot's description of the condition discovered by him during the lethargic stage of hypnotism, and designated by him neuro-muscular hyper-excitability. After reviewing Charcot's views and conclusions at some length, concerning this phenomenon, Dr. Morton concluded that neuro-muscular hyper-excitability is not alone found in the hypnotism of the hysterical, but that it may exist in ascending neuritis which has reached the spinal centres.

DR. C. K. MILLS, of Philadelphia, said that Dr. Morton's case called to mind several cases of brachial neuritis which had fallen under his observation, and in one of them the phenomena spoken of under the term neuro-muscular hyper-excitability was present in one arm at least.

In one patient, also, symptoms had developed in the other arm, as in Dr. Morton's case.

As to the question of neuro-muscular hyper-excitability, it presented one of the best fields for discussion, from a scientific standpoint.

DR. GIBNEY, of New York, had found that it was in cases of Pott's disease where the excitability of the muscles was most marked the most perfect cure could be promised; and he queried whether the hyper-excitability in the class of cases under discussion might not have a bearing on prognosis.

DR. S. G. WEBBER, of Boston, had tried various measures in the treatment of neuritis, and had found that blisters yielded the most satisfactory results.

DR. W. A. HAMMOND, of New York, advocated that rest of the nerve, as far as possible, should be insured, believing it to be one of the most essential elements in effecting a cure. He believed that the only way in which stretching an inflamed compound nerve could act was by securing for it rest.

DR. WEBBER sustained Dr. Hammond's view concerning the efficacy of rest.

DR. PUTNAM, of Boston, referred to the special efficacy of ice. If ice is used day and night, or a great many hours in succession, precautions being taken not to have the cold too great (protect the skin with flannel), it is of the greatest possible value.

DR. C. L. DANA, of New York, then read a paper entitled

NOTE ON HYDROBROMIC ACID AS A SUBSTITUTE FOR THE BROMIDES.

After making brief reference to the literature of the subject, Dr. Dana stated that this acid had been used by the profession chiefly with quinine, under the belief that it prevents or lessens cinchonism.

The only extended record of clinical observations regarding this acid that he had been able to find was one by Massini, published two years ago, who used it in thirty-one cases of various kinds without special benefit. Dr. Dana was led to experiment with the drug, with the hope that it would produce the beneficial effects of the alkaline bromides in epilepsy without causing depression and scurvy. He had now used hydrobromic acid in the treatment of various nervous affections for nearly two years at the Northeastern Dispensary, and had the clinical notes of over fifty cases of various kinds.

The officinal dilute acid is a ten per cent. solution, of which the dose would be from one drachm to two drachms and a half, well diluted. In *epilepsy* some patients received marked benefit from the use of the acid in doses of four to five drachms a day. Dr. Dana believed, however, that in epilepsy hydrobromic acid could not be used as a substitute for the bromides, except in the non-controllable cases, and yet it undoubtedly has a controlling influence over the disease.

In *chorea* he thought the acid could be used advantageously as a medium for arsenic or strychnine when it is desired to give a sedative. In *alcoholism* it failed in two cases, the patients being on the verge of delirium, and the bromides with chloral were subsequently given with relief.

Hydrobromic acid is a good solvent of quinine, but it does not prevent cinchonism, as has been asserted, certainly not in the small doses usually prescribed. In most cases of *insomnia* it also acts well. He could say positively that he could give the acid with just as much confidence that it would produce nervous sedation as when the alkaline bromides are prescribed. He had never seen any sign of bromism or any disagreeable constitutional effect other than some drowsiness. He believed that the ordinary custom of prescribing from twenty minims to one drachm of the three per cent. solution, the strength ordinarily employed, or of a ten per cent. solution, was generally much too small a quantity. Theoretically, in order to get the sedative action, from a

drachm and a half to two drachms and a half of the ten per cent. solution must be prescribed. Practically he had found that very satisfactory sedative effects could be produced with drachm doses of the officinal dilute solution. In conclusion, the acid could be substituted for the bromides in all the milder affections for which the latter are used. It had appeared to him to be especially efficient in producing vascular and nervous sedation in the post- and pre-hemiplegic conditions. Unless given in very large doses, it takes several days to get its best sedative effects.

DR. W. A. HAMMOND used hydrobromic acid for seven or eight years, and then abandoned it because he did not see that it did any good. He had found, however, that it does prevent the unpleasant effects of sulphate of quinine; but in this respect it is not so efficacious as a corresponding dose of the alkaline bromides.

Dr. Hammond's experience concerning the power of this acid to prevent cinchonism was corroborated by DR. ESKRIDGE, of Philadelphia, who also spoke of the good effects of the drug in typhoid fever.

The discussion was closed by Dr. Dana.

DR. J. J. PUTNAM, of Boston, then read a paper entitled

LEAD-POISONING SIMULATING OTHER DISEASES—A SOURCE OF ERROR IN THE ANALYSIS OF THE URINE FOR LEAD.

Within the last few years a number of cases had come to his notice in which examination of the urine had shown the presence of lead, while the symptoms and clinical history were not such as are usually considered characteristic of lead-poisoning; in fact, simulated other types of disease. So far as he knew the first case in which lead was supposed to have given rise to symptoms simulating any other form of spinal disease than poliomyelitis anterior, was one reported by Dr. F. Minot, of Boston, and published in the *Boston Medical and Surgical Journal* in 1881. In that case the symptoms of so-called lateral sclerosis were present to some degree, lead was twice found in the urine, and the patient improved materially under the use of iodide of potassium.

In none of the eight cases reported by Dr. Putnam were the blue line upon the gums, colic, emaciation, or discoloration of the skin, the characteristic localized atrophic paralysis, or typical cerebral symptoms present, and the diagnosis was established solely through the examination of the urine after the administration, for a few days, of iodide of potassium. All the chemical work of the investigation was done by Prof. E. S. Wood, in the laboratory of the Harvard Medical School.

Under the vague term lead encephalopathy a variety of nervous symptoms have been described, of which delirium, mania, dementia, epilepsy, and coma are at once the severest and the better recognized; but the disease is, no doubt, capable of giving rise to a variety of less slowly marked but not less important signs.

CONTAMINATION OF WATER BY LEAD.

Apropos to the contamination of water from leaden pipes, Dr. Putnam mentioned that while it was well known that hot water is more apt to dissolve lead than is cold, it is not, probably, so generally realized that this fact makes it objectionable to run hot and cold water pipes side by side through houses, especially when the latter carry water for drinking purposes. He had been assured by a reliable plumber that under such circumstances the cold water pipes were apt to be considerably corroded.

The quantity of urine examined should be at least one quart, and it should be collected during the administration of iodide of potassium, given either for the first time or after an interval of repose.

One source of error has recently suggested itself to Prof. Wood, and that is that the tests hitherto used for lead apply equally well to bismuth, a drug very fre-

quently prescribed. To avoid error, therefore, it was necessary to make sure that the patient has taken no bismuth within a considerable period before the examination for lead is made.

The paper was discussed by Dr. Webber, of Boston, who had noticed disturbances of sensation in every case of lead-poisoning, affecting the spinal cord, which he had examined. He also directed attention to an additional source of error in examination of the urine, namely, that when decomposition occurs, a chemical reaction takes place between the urine and glass by which lead is set free, and responds to test for that metal. Add a small quantity of acetic acid to the specimen to be examined, in order to eliminate this source of error; by Dr. Mills, of Philadelphia, who spoke of the protoplasmic effects produced by lead, as suggested by Ringer. The discussion was closed by Dr. Putnam.

DR. PUTNAM exhibited a urinal for use by female patients while sitting in a chair. It was a small copper basin, a miniature bath-tub, with a metallic conducting tube from the bottom of the outer, or broad end, to which could be attached a piece of rubber tubing.

The Association then adjourned to meet at 8.30 P.M.

FIRST DAY—EVENING SESSION.

The Association was called to order by the President.

DR. J. T. ESKRIDGE, of Philadelphia, read a paper, which contained the report of a case of

GENERAL NEURALGIA.

G. B.—, a German: aged twenty-nine; married; a laborer in a foundry; denied ever having had venereal disease. There was no external evidence of specific disease, and his children, three in number, were well developed and healthy. He enjoyed good health until the year 1873, when he suffered from an attack of pneumonia affecting the left side, and was confined to his bed four weeks. Two years ago, after sleeping one night in a damp bed, he noticed a dull heavy pain in the dorsal and lumbar regions of the spine. This pain continued about one month, and was then accompanied by severe pain in the course of the left sciatic nerve. During these two months he managed to hobble to and from his work, a distance of several squares, and was compelled to stand on his feet about two hours daily. The following summer he was able to walk quite well, although a little pain was experienced when the left sciatic nerve was firmly pressed upon. In October, 1881, melted iron fell into his left shoe and burned his ankle severely. The burn was mostly superficial, but its area was greatest around the internal malleolus; on the outer aspect of the ankle the area was small, but the wound extended to the bone. For this burn he remained in the hospital of the University of Pennsylvania ten weeks, and left comparatively free from pain, and returned to his work. One week later he began to experience great pain in the left leg and ankle. This attack lasted about one month, and the pain was greatly relieved by pressure over the sciatic nerve as it emerged from the pelvis. During the next ten weeks he suffered more or less pain, but was able to work. In October, 1882, he remained five weeks in the hospital suffering from severe pain, which extended from the lumbar region down the posterior portion of the thigh and leg to the left foot, most intense in the ankle. He improved somewhat in the hospital, but after returning to his work the pain became worse than it had been at any previous time. In January, 1883, he was scarcely able to walk, complained of great pain in the leg and back, sleep was broken, appetite capricious, bowels constipated; temperature, 100; pulse, 92; respiration, 24. His spine was tender on pressure in the dorsal and lumbar regions. All the superficial nerves of the left leg and gluteal region were the seat of neuralgic pain, and light pressure over any portion of the affected nerve greatly increased his suffering. Nothing, except hypodermic in-

jections of morphia and atropia, afforded any relief, and the effect of these medicines soon diminished. Chloroform injections increased rather than diminished his pain. In February the internal saphenous and genito-crural nerves became neuralgic, the left side of the scrotum was red and burned like fire, and was exceedingly sensitive to the touch. The right side was normal. Double intercostal neuralgia soon became well established and nearly constant. The only relief afforded the patient came from the alternate use of hot and cold applications to the spine and painful sciatic nerve; bladders filled with ice, and rubber bags with hot water were alternately applied every five minutes for an hour each day. When this was faithfully carried out the pains were greatly lessened, no morphia was required, and the patient's appetite and general condition improved, and finally the man could walk slowly about the wards. Most of the large superficial sensitive nerves were painful to pressure; the left fifth cranial nerve alone having escaped.

The question of diagnosis was one surrounded with some difficulties. Has not the case been one of general neuritis following inflammatory spinal trouble and improved? In favor of general neuralgia were the following reasons:

First.—It is a disease which has extended over a period of more than two years, made up of pain lasting from two to six months in a man whose condition and general appearance to-day seemed to be as good as they were after the first attack in the year 1881.

Second.—That several times by firm pressure over the great sciatic nerve, as it emerges from the pelvis, he had succeeded in relieving pain in the foot and leg.

Third.—That in inflammatory condition of the cord of so long duration reaction of degeneration and other trophic disorders would probably be found, and improvement would be slower if it occurred at all.

Fourth.—That the left leg and right fifth cranial nerve were severely affected, while the left side of the face entirely, and the right leg almost entirely escaped.

Fifth.—That pain was often shooting or steady in character, differing from the dull pain of neuritis.

Syphilis was eliminated not only by the history of the case, but by treatment.

The paper was discussed by DR. WEBBER, of Boston, who thought the fact that electrical reactions of the muscles were not disturbed militated against general neuritis or polio-myelitis.

DR. LEONARD WEBER, of New York, regarded the case as one of spinal lepto-meningitis, of which he had seen two similar ones within the last two months.

DR. ESKRIDGE could not accept Dr. Weber's view of the case until autopsies have been obtained which will throw light upon the cases in which apparent recovery takes place.

DR. C. K. MILLS, of Philadelphia, then read a paper on

LOCOMOTOR ATAXIA TERMINATING AS GENERAL PARALYSIS OF THE INSANE.

The author said that the relation between locomotor ataxia and general paralysis of the insane had been a problem of interest to neurologists and alienists since the investigations of Westphal in 1863. He then related the history of a case occurring in a man, forty-seven years of age, of good constitution, who had been treated most of the time for three years for "rheumatism," when he came under Dr. Mills' observation. The patient was addicted to venereal excesses and occasionally abused the use of alcohol. There was no evidence of secondary or tertiary symptoms of syphilis, although, many years before, he had had what was called a chancre. There were absence of paralysis, preservation of galvanic and faradic reactions, inability to walk well in the dark, swaying when standing with his eyes shut or heels together, numbness and tingling in the feet, sharp, sudden pains in the limbs, awkwardness with his hands in dressing, sense of con-

striction in the lower part of the abdomen, diminished sexual desire, marked loss of flesh, insomnia, mental anxiety, but not aberration of mind, absence of delusions. Improvement temporarily under treatment. Decided mental symptoms first developed two years after coming under treatment, when he spent his money very freely; had queer and lofty ideas, but the delirium of grandeur did not manifest itself until about one year later. Nearly three years after the notes first made by Dr. Mills concerning the spinal symptoms, and nearly six years after the development of ataxic pains, the patient was sent to the Insane Department of the Pennsylvania Hospital. His symptoms increased in severity and he finally died in the State Hospital for the Insane at Danville, Pa., five years and four months after first coming under Dr. Mills' care, and about eight years after he was first affected with ataxic pains. The autopsy revealed opacity of the cerebral pia, particularly in the postero-frontal and parieto-temporal regions, with congestion and adhesion at points, marked decortication and atrophy of the convolutions. The pia of the cerebellum, especially over the superior vermiciform process, was deeply congested and adherent. The pia of the cord was thickened, and the substance of the cord presented a shrunken and irregular appearance.

Microscopical examination showed marked sclerosis of the posterior columns throughout the whole extent, with general inflammation and thickening of the pia mater. Sclerosis was also present in the pons, crura, optic thalami, and convolutions examined, and in the cerebellum.

In this case the spinal symptoms were the first to appear. Dr. Mills referred to the views of various authorities concerning the relation of locomotor ataxia and general paralysis of the insane. According to Westphal and Hammond no direct relation exists between the morbid process in the cord and that in the brain; neither disease is secondary to the other; they simply co-exist as the expression of an excessive proclivity to diseases of the nervous system.

Dr. Mills also referred to cases reported by Obersteine, Hamilton, Plaxson, Mickle, and others.

The paper was discussed by Drs. J. C. Shaw, of Brooklyn; W. R. Birdsall, of New York, who directed attention to the possible relation which might exist between meningitis and sclerosis of the substance of the cord; Weber, of New York, who had had cases similar to that reported by Dr. Mills; Morton, of New York, and Webber and Putnam, of Boston.

Dr. E. C. SPITZKA, of New York, then read a paper entitled

REMARKS ON THE ALLEGED RELATION OF SPEECH DISTURBANCE AND THE PATELLAR TENDON REFLEX IN PARETIC DEMENTIA.

At the annual meeting in 1881, Dr. J. C. Shaw read a paper on the tendon reflex in general paresis, which contained the following conclusion: "The exaggerated reflex is closely associated with two prominent symptoms in this disease. Those cases in which there are marked difficulties of speech, hesitancy, stuttering, up to complete inability to speak, not aphasia proper, are the cases in which is always found, sooner or later, exaggerated tendon reflex," etc.

Certainly the suggestions which seemed to open up a prospect of establishing a physiological relation between the speech centres and the lumbar enlargement of the spinal cord would merit our serious attention if the proposition that such a relation exists were made but tentatively. Unfortunately, however, Dr. Shaw had adopted premises in drawing his pathological conclusions which cannot but have contained a source of error, as he had excluded from consideration the pathological condition of the brain. It occurs that in paretic dementia there is, as a rule, a diffuse affection of the entire central nervous axis. In some cases the lesions seem to be concentrated and intensified in the cord, in others in the cortex, and,

as Dr. Spitzka had had occasion to observe in a series of fifteen autopsies, in not a small proportion in the brain isthmus. A speech disturbance may be due to a high cerebral lesion, and may then be permanent; it may, on the other hand, be evanescent, and due to temporary vaso-motor causes. It may not differ in its mechanism particularly when associated with hemi-paretic attacks from speech disturbance following cerebral or meningeal hemorrhage. Speech disturbance may also frequently depend upon lesions in the medulla oblongata. Here, then, are a number of conditions which may in themselves be associated with changes in the tendon reflex.

The presumption of science is that there are few things in neurology as remote from each other as the tendon reflex and the speech function. Dr. Spitzka reported briefly eighteen cases from his private practice, most of which conflicted with the view advanced by Dr. Shaw.

Dr. SHAW said that his paper was on tendon reflex exaggerated, normal, and absent in paretic dementia; that he had observed seventy cases, and in twenty-two of these it was exaggerated; and that he merely put it forward as a clinical observation at that time. Of course he had been unable to prove it pathologically, and he never pretended to make any such connection between the spinal cord and the speech centres as would seem from Dr. Spitzka's paper.

The paper was further discussed by Dr. Putnam, of Boston, and the discussion was closed by Dr. Spitzka.

The Association then adjourned, to meet at 2.30 P.M., on Thursday.

THURSDAY, JUNE 21ST—SECOND DAY—AFTERNOON SESSION.

The Association was called to order by Dr. W. J. MORTON, of New York, Vice-President.

Dr. Ralph L. Parsons, of Sing Sing, N. Y., was elected a member.

The President, Dr. R. T. EDES, of Boston, then read a paper on

THE EXCRETION OF THE PHOSPHITES AND PHOSPHORIC ACID AS CONNECTED WITH MENTAL LABOR.

It seemed to the writer that there is a strong popular and scientific opinion that excretion of phosphoric acid is perceptibly or decidedly increased by mental labor; the most common form in which the statement is made being with regard to the increased elimination of phosphorus by clergymen on Mondays. He had not, however, been able to find the statement distinctly made by the original authority, Dr. Holmes. Whether or not it was based upon the statement of Golding Bird he did not know; but if so it does that eminent physiologist much injustice, as he does not speak at all of the elimination of phosphoric acid, but of the deposit of earthy phosphates, and refers to Sunday service not as intellectual labor, but as bodily exertion and anxiety. The technical difficulties in the way of such an inquiry—if the condition be at all a marked one—are almost none at all, since the determination of the presence of the phosphates with reasonable accuracy was a very simple process. But it is not so easy to make a distinction between mental labor and mental rest a very marked one. We have no accurate scale for mental labor corresponding to the foot or pound of mechanical work done, and it is very obvious that degrees of mental exertion are utterly without correspondence to the value of results obtained. The feeling of fatigue or consciousness of mental effort, is, perhaps, the only means that we possess of estimating the intellectual labor. This, it is evident, may as well result from the adding up of a most meaningless column of figures as from the composition of a sonnet. A certain admixture of bodily and mental labor is also unavoidable if anything like speaking or writing is attempted.

Dr. Edes gave the results of observations made upon

himself. The earlier ones embraced only the times of a lecture and a few hours afterward. But as it might be objected that phosphoric acid formed during the greatest period of mental activity, and only slowly finds its way into the blood and out of the excretory organs, he made a few others in which the examination was made not only for the evening but for the succeeding night. In some of these the earthy phosphates were separately estimated, with the result of giving about the ordinary proportion, showing nothing of special interest. From his experiments it was seen that phosphates were diminished rather than increased during the process of mental action, as, for instance, during a lecture. Would it be fair from these figures to infer that no phosphorus is used up in the process of cerebration? Certainly not; but they are sufficient to show that the amount of phosphates derived from the metamorphosis of brain-tissue in a condition of physiological activity is so small in comparison with that from the system generally, that it has no perceptible effect upon the total of phosphates found in the urine.

DR. JEWELL, of Chicago, being called upon, said that while he had not made investigations such as those made by Prof. Edes, he had studied the subject somewhat in the light of common sense, as the question had been very frequently asked him, and he had been unable to see why the brain, in even a tolerably protracted mental effort, should so extraordinarily increase the compounds into which phosphorus enters as to make any great change in the quantity found in the urine. It had seemed to him to be almost absurd, and he was glad to have the support of Dr. Edes' investigations.

DR. F. T. MILES, of Baltimore, suggested that phosphorus existing in nerve structures had been detected only in the white substance of Schwann, and not in the protoplasm of the ganglionic cells.

The paper was further discussed by Dr. Ott, of Easton, Pa., and the discussion was closed by Dr. Edes.

DR. S. G. WEBBER, of Boston, then read a paper in which he reported

CASES OF LOCOMOTOR ATAXIA, INTERESTING ON ACCOUNT OF UNUSUAL SYMPTOMS AND ON ACCOUNT OF MARKED REMISSION IN THEIR COURSE.

Case first was one of severe *gastric crises*, without other prominent symptoms. The patient was a man fifty years of age, and the case was interesting from the extreme violence of the gastric symptoms, to which no words could do justice. There was, however, very little vomiting. The disturbance showed itself in severe attacks of flatulence attended with pain.

Case two was of interest from the *restriction of respiration*. Dr. Webber had seen this in one other patient. The attacks recalled laryngeal spasm, but there was no cough. The sensation was probably an unusual form of the girdle sensation.

The third case was characterized by *diabetes*, and occurred in a male patient fifty years of age. The diabetic condition was associated with occipital pain, and was the combination of symptoms which attracted especial attention.

The fourth case occurred in a male fifty-three years of age. *Deafness* has been seen only a few times in locomotor ataxia. Erb reports a case, and other cases have been reported. Sometimes the deafness is unilateral, sometimes it is only partial. The following case was one in which the deafness was such that the voice could not be heard. Probably the lesion is similar to that which is found in atrophy of the optic nerve. The patient was examined by Dr. C. J. Blake, of Boston, who gave it as his opinion that the condition of the ears would not account for the patient's deafness. In the remaining cases, either the patellar reflex was not lost, or it returned. At least, temporary reappearance was obtained in some. The first five cases reported were chiefly of interest on account of the unusual individual symptoms. The last three cases, making in all eight,

were of interest as regards the prospect of improvement, whether great benefit or cure may ever be expected in locomotor ataxia.

Case six might be regarded as virtually cured, as the patient had remained free from symptoms for three or four years. It is reasonable to think that when the symptoms develop rapidly, the prognosis is more favorable than in other cases.

The paper was discussed by Dr. G. L. Walton, of Boston, who had examined over forty patients suffering from locomotor ataxia, with special reference to deafness, and in not a single instance could the deafness which was present be attributed to degeneration of the auditory nerve. In none was hearing for high tones lost, and hearing was best through bone on the side where the deafness was most marked. The cases of deafness as a symptom of locomotor ataxia, as Dr. Edes had said, were extremely rare, hence the special interest of the case reported.

DR. JEWELL, of Chicago, directed special attention to the great efficacy of *absolute rest* in bed for months, with passive exercise to keep nutrition in as good condition as possible, as being the *most important of all* measures in the treatment of locomotor ataxia. The rest must be rigidly maintained to be of value.

The paper was further discussed by Drs. Morton and W. A. Hammond, of New York, and the discussion was closed by Dr. Webber.

DR. R. W. AMIDON presented a case of

TETANOID PARAPLEGIA

occurring in a child, the tetanoid symptoms being preceded by a train of symptoms indicating subacute hydrocephalus.

He made the query whether the central trouble could not, by causing descending changes in the cord, account for the tetanoid symptoms, the etiology in most cases being obscure.

Dr. Amidon also presented two anomalous cases of

PARKINSON'S DISEASE,

the peculiarity consisting in entire absence of tremor, every other symptom of paralysis agitans being present.

DR. GIBNEY presented a patient illustrating

PROGRESSIVE MUSCULAR ATROPHY WITH MARKED FIBRILLARY TWITCHINGS.

He also presented a patient with fibrillary twitchings following a gunshot wound.

DR. MORTON then read a paper and exhibited an apparatus for the treatment of

WRITER'S CRAMP.

Among the non-fatal diseases of the nervous system there are none probably less curable or more disastrous to the patient's occupation than is writer's cramp. He had obtained better and more lasting results by the method of stretching the muscles affected by the cramps than by any form of electricity. After referring to Wolff's method of treatment, reference was made to the method of treatment devised by Nussbaum, of Munich, who utilizes the idea of bringing the extensors into play in the act of writing, and thus resting the flexors and abductors of the thumb. Dr. Morton thought that the principle could be applied in a much more simple way than by means of Nussbaum's apparatus, and had therefore devised what was practically a thimble-pen; that is to say, it is a long thimble worn on the entire index finger. To the end of this thimble is attached a stub-pointed pen. The thimble should be of very light elastic metal, split from end to end, should be made for the finger and clasp it entirely. A very slight rubber elastic band, such as is commonly used on writing-desks, slipped over the thumb and fingers, serves to steady and offer a moderate amount of resistance to extension or abduction. The patient now writes by the usual shoulder movement of free writing, holding the hand flat upon the paper and sliding it

along. The natural tendency of the finger and thumb is to extend rather than contract, as in holding the ordinary pen, and the result is that the patient, with very little experience, learns to write a good hand and without the slightest experience of cramp or spasmodic movement.

The paper was discussed by DR. PUTNAM, of Boston, who thought one objection to the theory of the apparatus existed in the fact that we cannot say that simply diverting the muscles is the essential thing. He also thought it to be questionable whether the extensors could be called upon to take this forced position without also suffering; by DR. DANA, of New York, who thought the device an ingenious one, and suggested that it could be resorted to as a prophylactic measure; by DR. WEBBER, of Boston, who thought that learning to write with the opposite hand was as practical and satisfactory as any means that had been suggested; by DR. WALTON, of Boston, and DR. MORTON.

A paper by DR. E. C. SEGUIN, of New York, entitled "The Insane of Spain and their Asylums," was read by title, after which the Association adjourned to meet Friday at 2.30 P. M.

On Thursday evening Dr. R. W. Amidon gave an elegant but informal dinner at Delmonico's to the President, Dr. R. T. Edes, the members of the Association, and numerous invited guests. Toasts were responded to by Rev. Dr. Collyer, Drs. Edes, Otis, Miles, J. C. Peters, Putnam, R. W. Taylor, Mundé, Ridlon, and others.

Dr. W. J. Morton also gave a brilliant reception at a later hour, at which there was a large attendance not only of the members of the Association, but of the medical profession of New York.

FRIDAY, JUNE 22D—THIRD DAY—AFTERNOON SESSION.

The Association was called to order by the President.

Dr. J. Leonard Corning, of New York, was nominated for membership.

The Secretary presented a large volume received from Dr. J. J. Mason, entitled "The Central Nervous System of Reptiles." It was accepted with thanks.

DR. GREME M. HAMMOND, of New York, presented a patient who had suffered from

LOCOMOTOR ATAXIA.

The patient was a man thirty-two years of age, who had been referred to him by Dr. James H. Anderson. Early in the history he suffered from the characteristic pains of locomotor ataxia, there was absolute loss of tendon reflex, and the ataxic gait was well marked. A long while ago the patient had a sore upon his penis, but no evidence of either secondary or tertiary symptoms of syphilis could be obtained. The treatment had consisted in the use of electricity, iodide of potassium, and general measures, and every symptom of the disease had disappeared, and the tendon reflex had returned very considerably.

DR. W. A. HAMMOND corroborated the diagnosis, and the case was discussed by Drs. PUTNAM, of Boston, and MILES, of Baltimore.

DR. F. T. MILES, of Baltimore, then reported a case which illustrated

NUTRITIVE ALTERATION IN THE HAND FROM PRESSURE OF THE HEAD OF A DISLOCATED HUMERUS IN THE AXILLA.

The interesting points were the great amount of deformity, with glossy skin, insensibility not only to touch but to heat and cold, the loss of power in the muscles, with great deformity of the little and ring fingers, and all developed slowly by pressure of the head of the humerus in the axillary space, with pain located entirely about the shoulder.

Dr. Miles thought, if the question was thoroughly

studied it would be found that these various forms of neuritis were capable of altering function without developing many subjective phenomena; that neuritis may progress without absolute pain, and produce alterations in tissue without giving rise to many of those symptoms which it was generally thought should be present when a nerve is inflamed.

DR. BURT G. WILDER, of Ithaca, then read a brief paper

ON THE BRAIN OF THE CAT LACKING THE CALLOSUM.

Although there have been recorded several cases of more or less nearly complete absence of the great cerebral commissure with human beings, the specimen exhibited (with photographs) seemed to be the only case of the kind among the lower mammalia, being the only case occurring in the anatomical laboratory of Cornell University among the several hundreds of cats' brains there examined. There was no trace of the callosum, nor of the fornix beyond the dorsal limits of the portæ (foramina Monroi); the præ commissure and medi commissure are larger than usual. Unfortunately nothing whatever was known of the history or habits of the cat. Now that the unique specimen had been submitted to the Association, Prof. Wilder will be more free to dissect it.

Dr. Wilder read another brief paper

ON THE ALLEGED HOMOLOGY OF THE CARNIVORAL FISURA CRUCIATA WITH THE PRIMATIAL FISSURA CENTRALIS.

Referring to the assumption of T. Lauder Brunton (*Brain*, January, 1882), "that these fissures correspond," Prof. Wilder made the following suggestions:

First.—Writers should specify whether by correspondence they mean *analogy* or *homology*, as a relation based upon the position of a fissure based its location among experimentally determined "motor areas," or a relation implying identity as determined by embryology and comparative anatomy.

Second.—The present disagreement of competent authorities respecting the homology of these two fissures should restrain both physiologists and zoölogists from assuming the correctness of any particular view; for example, the human centralis has been homologized with not only the cruciate, but the superorbitalis, the coronalis, and the ansata together with the coronalis (in connection with the last idea was shown a fetal human brain, exhibiting the somewhat rare condition of an interruption of the centralis); the cruciate has been homologized with not only the centralis, but with the first frontal, the calloso-marginalis, and the occipito-parietal; *i.e.*, the surest method of determining the true homology seems to be the one which is outlined in Wilder and Gage's "Anatomical Technology," to make careful and extended comparison between the brains, especially fetal specimens of man, monkeys, and the *lemurs* on the one hand, with those of cats, dogs, and seals on the other.

The lemurs are primates with some characters of the carnivora, while the seals, though carnivora, have the occipital lobe and the post cornu of the procellia (cornu posterius of the ventriculus lateralis).

These papers were discussed briefly by Drs. Morton, Miles, Mills, Birdsall, and Hammond.

DR. W. J. MORTON, of New York, then read a paper "On the Treatment of Migraine." [It will appear in full in a subsequent number of *THE RECORD*.] It was discussed by Drs. W. A. Hammond, J. L. Corning, J. J. Putnam, Burt G. Wilder, F. T. Miles, C. L. Dana, C. K. Mills, and the discussion was closed by Dr. Morton.

DR. W. R. BIRDSALL, of New York, presented statistics with reference to

THE RELATION BETWEEN SYPHILIS AND LOCOMOTOR ATAXIA.

He had collected 525 cases of locomotor ataxia, of which 225 patients had syphilis, or 43 per cent. The cases

were from Rosenthal, Bernhardt, Remak, Westphal, Pusinelli, Gowers, Fournier, Erb, together with 42 which had come under his own observation. It was noticed that there was a marked difference in the percentage of syphilis in the cases reported by different observers. For instance, Erb, in 100 cases, reports syphilis present in 88 per cent., while in his own cases (42) only 4 per cent. of the patients had syphilis. Probably the differences were due to accidental relations.

Dr. Birdsall also exhibited

AN ELECTRODE FOR MAKING CAREFUL ELECTRICAL TESTS, and also for therapeutical purposes. It was a hand electrode, so arranged that the current could be interrupted and reversed at the same time. The communication on syphilis was discussed by Dr. Mills, of Philadelphia.

The Convention then adjourned to meet at 8.30 P.M.

THIRD DAY—EVENING SESSION.

*A communication from Dr. H. D. Schmidt, of New Orleans, "On the Pathological Anatomy of the Cerebro-Spinal Axis in a Case of Chronic Myelitis of nineteen years' standing," accompanied by photographic illustrations, was read by title.

GALVANIZATION OF THE BRAIN AND ITS VALUE IN THE TREATMENT OF CHOREA.

DR. C. L. DANA, of New York, read a paper on the above subject, in which he said that, as regards the phenomena which result from passing a galvanic current through the healthy human brain, the effects may be classified under those of subjective or those of which the patient is conscious, and those which are objective or apparent and can be noted. Then followed a classification of the phenomena, succeeded by a classification of therapeutical results which can be obtained in the diseased brain with more or less certainty.

As a result of direct electrical irritation of the exposed brain of animals, certain phenomena are obtained not observable when the cranial bones are interposed. Then followed tables containing the results of experiments.

A question of great interest is: In what way does the galvanic current produce the phenomena which result when precutaneously applied to the brain? Dr. Dana's conclusions concerning precutaneous galvanization of the brain were:

First.—That it is one of the most easily reached and easily affected of central organs.

Second.—That in ordinary galvanization, the polar method and the polar nomenclature should be used, as it is the pole and not the direction of the current which produces specific effects.

Third.—That the anodal galvanization of the brain probably lowers cerebral irritability, contracts the pial vessels, slows the circulation and produces effects on the nutrition of the brain.

Fourth.—That its action is chiefly a direct one, but is supplemented by reflex processes.

Fifth.—That possibly more powerful or special polar effects may be produced by using widely separated electrodes.

CHOREA.

Dr. Dana, having thus given the theoretical basis for the practical use of electricity in chorea, said he believed that ordinary chorea minor is an irritative disease of some part of the voluntary motor tract. The irritation may be chiefly in the spinal cord, or chiefly in the brain, as with the ordinary chorea of children.

Chorea is not a disease which should be left to Nature. It often, indeed generally, runs a typical course, but in the beginning the physician can never say whether or not it will cling to the child for months or years; hence the best therapeutical means should be promptly applied. Dr. Dana then reviewed the reports as to the value of electri-

city in chorea, and found that they had been most conflicting. It had seemed to him, however, that the agent, so far, had been applied irrationally. By acting upon the hypothesis that anodal galvanization of the brain *ought* to prove sedative in functional spasmodic troubles of cerebral origin, he began some time ago to use this method in the treatment of chorea. It was not until recently that he learned, in Erb's work, that Berger also had been using anodal galvanization of the brain in chorea; neither of the authors, however, had given detailed reports of their cases. Dr. Dana reported eight cases. The patients all recovered. The average duration was thirty-four days; the average duration of treatment, twenty-five days. It was not upon the statistics of duration, however, that he was led to believe in the efficacy of anodal electricity. What he claimed for anodal galvanization is that it is a most valuable adjunct in the treatment of chorea; that given daily for a week or ten days with arsenic, and probably without, it will materially shorten the duration of the disease.

The method of application is as follows: A large sponge-electrode of flexible brass, 4 x 2 inches, is thoroughly moistened with salt water. The hair of the patient is also thoroughly wetted and the electrode applied over the side of the head above the ear. In hemichorea it need only be applied over the side opposite to the one affected. The other electrode is placed in the hand of the affected side. The electrode upon the scalp is made positive, and a current, three to six Stohrer's, four to eight Daniell's cells, is passed for from three to five minutes. The electricity should be applied daily for at least ten days. If after that time there is no improvement it may be discontinued.

DR. CORNING, of New York, was convinced of the efficacy of central galvanization in the treatment of chorea, with or without arsenic.

DR. MILLS, of Philadelphia, agreed largely with Dr. Dana concerning the efficacy of galvanization of the brain in chorea, but took some exceptions to the theory advanced concerning the mode of action. There were very many things which led him to believe that the effect, so far as the brain was concerned, was *indirect* or of a reflex character.

DR. WEBBER, of New York, thought the reflex action was probably the most important to consider. He had no doubt of the refreshing effects of electricity passed through the head, but had found that only a few cells of a good battery were necessary to give the desired results; three elements for children, four to six, utmost eight, for adults.

The paper was further discussed by Drs. Birdsall, Corning, and Morton, and the discussion was closed by Dr. Dana.

DR. BURT G. WILDER, of Ithaca, then read a brief paper

ON THE REMOVAL AND PRESERVATION OF THE HUMAN BRAIN.

It referred to the removal of the calvaria, which should never be done with a jerk, but by sawing through a little to one side of the great longitudinal sinus, and then removing the sides carefully after releasing the dura by means of a thin-bladed flexible knife with curved point. The brain should never be allowed to support its own weight, but should be suspended in strong brine. Several points concerning the handling of the brain were mentioned. The preservation was by means of alcohol, beginning with fifty or sixty per cent. and gradually increasing the strength until the ordinary ninety-five per cent. is reached. He also passes alcohol through the vessels of the brain in a continuous stream for some time, and, besides, irrigates the central cavities of the brain. Whether brains hardened in this manner were well preserved for microscopical examination he was unable to say.

DR. SPITZKA said that the process recommended by Dr. Wilder was absolutely worthless for the histologist

and pathologist, but was doubtless an excellent method for the comparative anatomist.

The communication was discussed somewhat by Drs. Mills, Miles, Spitzka, and Wilder.

DR. WILDER then began a paper

ON SOME POINTS IN THE ANATOMY OF THE HUMAN BRAIN, but owing to the lateness of the hour did not complete it. So far as he presented it the object was to show that we need greater accuracy in our methods of dissection than have been followed in general.

A paper by DR. E. C. SPITZKA, entitled "Lesion of the Stratum Intermedium," with remarks on the anatomy and physiology of that tract, illustrated by specimens, was read by title.

A paper was presented by DR. G. L. WALTON, of Boston, in which were reported

TWO CASES OF HYSTERIA: 1, HYSTERICAL HEMI-ANÆSTHESIA IN A MAN FOLLOWING INJURY; 2, HYSTERICAL ANÆSTHESIA OF SPECIAL SENSE ACCOMPANYING CUTANEOUS HYPERÆSTHESIA.

The first was interesting with regard to its etiology. A strong, robust man, without a trace of nervous history, who, following a fall upon his head and shoulder, had, besides other symptoms, typical hysterical hemianæsthesia.

The second case was interesting in that there was anæsthesia of the special senses, hearing, smell, taste, whereas the skin over these organs was hyperæsthetic, entirely contrary to the rule.

Both cases yielded under the use of the magnet.

The Association then adjourned to meet at the call of the Council.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 16, 1883, to June 23, 1883.

GORGAS, W. C., First Lieutenant and Assistant Surgeon. The leave of absence granted in S. O. 51, par. 5, C. S., Department of Texas, extended one month. S. O. 63, Military Division of the Missouri, June 19, 1883.

WYETH, M. C., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Maginnis, M. T. S. O. 103, par. 2, Department of Dakota, June 14, 1883.

Official List of Changes in the Medical Corps of the Navy for the week ending June 23, 1883.

DAVID KINDLEBERGER, Medical Director, and F. M. GUNNELL, Medical Director. To the Naval Retiring Board.

M. H. CRAWFORD, Past Assistant Surgeon. From Navy Yard, League Island, Pa., to the U. S. S. Pinta.

JEROME H. KIDDER, Surgeon. Resigned, to take effect June 18, 1884, and granted leave till that time.

THOMAS J. TURNER, Medical Director. Orders of June 7th modified to continue on duty as member of the National Board of Health, till June 30, 1883.

ADULTERATIONS AND CHARITY.—A Spanish magistrate, shocked and exasperated by repeated proof of the adulteration of food in his district, has issued a proclamation aflame with righteous wrath, that "all articles in the shape of wines, groceries, and provisions, which upon examination and analysis are proved to be injurious to health, will be confiscated forthwith and distributed to the different charitable institutions."

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending June 26, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.

June 26, 1883.....	0	9	16	4	18	11	0	0

HEITZMANN IN BERLIN.—Dr. Heitzmann, of this city, described his peculiar histological views before the Berlin Medical Society, at its meeting on May 2d. These views, it will be remembered, are that the body tissues are not made up of cells, but rather of a reticulated network enclosing living protoplasm. In the discussion which followed Virchow responded to the attack made upon the cellular histology. His view, in brief, was that the fact of a cellular network, even if proved, was of secondary importance, and did not affect the theory that the cell is the physiological and anatomical unit of the tissue. That cells are the individual units and not part of a great ramification, he still believed, and instanced a number of facts in support of the opinion.

Dr. Fränkel, who was the only other speaker, contended, against the opinion of Heitzmann, that even healthy rabbits may be made tuberculous by the inoculation of non-tuberculous matter.

POISONING FROM CASTOR BEANS.—Dr. M. E. Alderson, of Russellville, Ky., writes: "It is the general impression among the laity, and also with many of the medical profession, simply because they have not had occasion to carefully examine into the history of the plant, that the *Ricinus communis*, or common castor-oil plant, is non-poisonous and harmless. Very few of the writers on *Materia Medica* ascribe to it any dangerous qualities. Pareira, of the older authors, speaks of serious effects from ingestion of the bean; and Stillé, of the modern, gives a number of fatal cases of poisoning from the same. As a consequence of this careless notice, the plant has gained a prominent place among the flowers in our gardens, and as the fruit has thus become easily accessible to children, I thought that the following cases might be of interest, put some on their guard, and perhaps save little *innocent tasters* from its terrible effects. On Sunday morning, April 8th, I was called to see Mattie and Mabel W—, aged respectively seven and three years. I was told by the messenger that they had, on the previous day, in the afternoon, eaten some castor beans, and had been vomiting and purging incessantly all night. Upon my arrival, about eight o'clock, I found both the little girls completely prostrated, with cold extremities and scarcely any radial pulse, in fact, almost in fatal collapse. The symptoms were very similar to those of cholera infantum. I immediately ordered mustard to stomach and bowels, and administered, as best I could—as the efforts to vomit came on every ten or fifteen minutes—a mixture of sulphuric ether, aque camph., and mucil. acaciæ. Under this treatment they seemed to revive a little. By keeping up the stimulant treatment and combating the intense nausea and thirst with cracked ice and small doses of bismuthi subnitrat and sulph. morphicæ, I succeeded in lengthening the intervals between

the attacks of vomiting, the purging having stopped early in the morning. After the thorough evacuation of the poison, we had for five days to contend with most acute attacks of gastro-enteritis, during which the little sufferers again came near losing their lives. They, however, withstood the shock, and are now convalescent."

HOSPITAL STRETCHERS.—Dr. Morison, writing from Berlin, of the Hygienic Exhibition, says (*Maryland Medical Journal*): "The best arrangement for carrying the ill to a hospital, or anywhere, is suggested by the exhibit of covered stretchers. This exhibition is made by Vienna, where an ill person is always carried in this way. No carriage or wagon can possibly be made as comfortable, or managed with so little danger to the patient. There is no exposure, for the covering is complete, and they are made so light that two men can easily carry any patient upon them. Ambulances may carry the stretchers, but the stretchers should carry the patients. Many an agonizing pain, and perhaps many a life, would thus be saved."

TO STOP HICCOUGH.—Dr. Martin Burke, of this city, sends us the following item: "Perhaps the narrative of these two cases may prove of interest. John C—— was suddenly seized about a year ago with an attack of hiccough. The cause was unknown. All the usual remedies were tried in vain. Dr. John Burke, my father, was then called upon. Noticing the convulsive heaving of the patient's ribs, more particularly upon the left side, he firmly compressed the side between his two hands, and in a short time the hiccough ceased for the first time in days. The second case was that of Mr. C——, a young man of thirty. He also was attacked, first with vomiting and then with hiccough, most violent and convulsive. Morphine suppositories would produce sleep, but even in sleep the hiccough was distressingly severe. As his vomiting had now ceased, almost every remedy known was called to our aid, but it was not until we had again, by my father's advice, compressed his heaving ribs, that the hiccough almost instantly ceased. It returned indeed within twenty-four hours, but compression again arrested it. The patient is now convalescing, and as hiccough very often proves fatal, perhaps the record of these two cases may prove of service."

TO DISGUISE THE ODOR OF IODOFORM.—Dr. J. A. Andrews, of Staten Island, N. Y., writes: "It may interest your readers to know that cumurin will disguise the unpleasant odor of iodoform. The Tonka bean has been employed for this purpose. The bean being placed in the bottle containing iodoform. This, however, is not effectual. Cumurin, itself a derivative of the Tonka bean, is an anhydrate of cumuric acid. It disguises the odor of iodoform more effectually and permanently than do other drugs with which we are familiar, nor does it form, when incorporated with iodoform, lumps of powder which are slow to dissolve, which is a real advantage where this drug is employed in the therapeutics of purulent inflammation of the middle ear. However, it is not the object of my communication to urge the claims of iodoform in the treatment of suppurative inflammation of the external or middle ear, because I believe it is of use only in certain selected cases of this affection, often actually aggravating the condition in others. The minimum amount of cumurin which I have found sufficient to disguise the odor of iodoform, is three grains of the former to one drachm of the latter."

MERCURY AND MALARIA.—HEMORRHAGIC MALARIA.—We have received a letter from Dr. Harris Fisher, of Eastman, Ga., containing an interesting discussion of the subject of hemorrhagic malaria, and criticizing some of Dr. W. O'Daniel's views on the subject of malaria as the cause of hæmaturia. The remarks upon the popular practice of giving mercury in malaria will excite some dispute. "We have," he writes, "just passed through a most notable epidemic of benign biliary jaundice. Every practitioner in this country has seen scores of cases. Catar-

hai duodenitis, with occlusion of the bile-duct, white feces, a stupid and depressed mental state, with an abnormally slow pulse in some instances as the extreme toxic effect of the bile. With a reappearance of bile in the feces a rapid clearing up of the skin. An inevitable deepening of the jaundice by any untimely exhibition of mercury. The pathological states giving rise to this icteric hue are entirely dissimilar: but as relates to the use of mercury, very similar, i.e., it can hardly fail to do harm in any case. Our own observation and experience go far to sustain the broad assertion that the occasion for the exhibition of mercurials in malarial fevers in general is seldom present. From what we have seen and read and heard related of the behavior of hemorrhagic malarial fever, we think it should here be used with the greatest circumspection. First, at some period or other of a malarial paroxysm the liver, as a rule, acts with unwonted energy. The hasty administration of a dose of calomel only adds profusion and acidity to the secretion. Depletion and an enhanced tendency to congestion follows as a sequence. The patient who has a chill to-day and takes blue mass, and has another on the third day, will vomit and pass more bile per anum than ever before. In hemorrhagic malarial fever it is the observation of most writers that the liver seems to act profusely: and certainly the catalysis of mercury is to be avoided where the death-rate of the oxygen carriers is simply fearful to contemplate. Dr. O'Daniel says 'malarial hæmaturia is malignant bilious fever, and nothing more.' This is a very debatable point. A monument should be erected to Thomas Watson for impressing so profoundly upon the practitioner the importance of studying the mode of death and tendency to death in every disease. The application of this hint to the point in question militates strongly against Dr. O'Daniel's position. In ordinary bilious or remittent fever, when it assumes a type worthy of the term malignant, the cause of death is generally breaking down under the prolonged and unrelieved congestion of the mucous coat of the stomach and similar changes in the liver and spleen. Prolonged high temperature is an important factor in producing the same results. Day after day, running into weeks, the patient may exhibit the dry, parched, almost black tongue, and vomiting continue until the secreting structures of the stomach begin to pass away in "coffee-ground" vomit, and death supervenes; and not a drop of blood be effused into the tissues, or stomach, or bladder; on the other hand, the patient yet on foot suffers in many instances from all these things, effusions, before taking his bed. The tendency to death is, in the latter case, eminently by anemia. It is true there is, perhaps, in all cases of hemorrhagic malarial fever more or less splenic and hepatic congestion, but the cause that carries off a man or woman in two or three days after going to bed is effusion of broken down blood; and the syncopal and asphyxial symptoms that immediately precede dissolution are in striking contrast to those that close the scene in a death from remittent fever. Patients suffering from severe remittent fever are apt to have it from the first. Hemorrhagic malarial fever is almost always concurrent with chronic intermittent. Dr. O'Daniel very correctly insists that there is more in the prophylaxis than the cure. His success is above the average. Whoever has chronic chills and determines to live in daily or nightly renewal of the contamination is liable at any moment to exhibit the signs of the dreadful disease. The recently malaria-bitten need not be uneasy. The causes that bring about this sudden death of the blood operate slowly. The following observations are, we think, justified by theory and experience: A complete differentiation from any other form of malarial fever: the jaundice accompanying is hæmaturic; the tendency to death is mainly by anemia; the use of quinine now and then precipitates an attack; mercurials are but little indicated; when periodic, the rhythm must be broken; the prophylaxis or hygiene of this disease is retreat.

INDEX.

A

Abdomen, rupture of walls of, 89; surgery of, 530.
 Abdominal section, 158, 258; consecutive cases of, 293.
 Abortion, 297; antiseptics after, 692; assa-fœtida in, 332.
 Abscess, cold, of the tongue, 515; intracranial, trephining for, 322; of the liver, 105; of the neck, 599; pelvic, 351; perinephritic, 433.
 Abscission, is it a proper operation? 669.
 Abstracts, the, 354.
 Acetonuria, 10.
 Acid, boracic, local application of, 209; carbolic, subcutaneous use of, in muscular rheumatism, 208; chronic, in the treatment of nasal polypi, 577; hydriodic, in acute rheumatism, 448; hydrobromic, a substitute for the bromides, 713; lactic, in diabetes, 155; muriatic, in typhoid fever, 212; phenic, 672; in typhoid fever, 9; phosphoric, excretion of, 714; picric, as a test for albumen in the urine, 193, 404; salicylic, ergot as a preventive of poisonous effects, 571; salicylic, in night-sweats, 94; sulphurous, in phthisis, 195; uric, abnormal in various secretions, 93; uric, and renal concretions, 708.
 Acne, 151.
 Aconite, dose of, in the British Pharmacopœia, 168; the proper way to give, 56.
 Acton, Dr. Wm., notice of book by, 299.
 Addison's disease, 179; and the suprarenal capsules, 489.
 Adipocere, 493.
 Adonis vernalis, a cardiac stimulant, 160.
 Agnew, Dr. C. R., remarks made at State Medical Society on the Code of Ethics, 349; the care of the chronic insane, 138.
 Air, entrance into the pleural cavity, 301; how to purify, of the sick-room, 335.
 Air-baths, 408.
 Albumen, picric acid as a test for, in the urine, 193, 404; tests for, 307; in ascitic fluid, 93.
 Albuminuria, from contusion of the loins, 238; hygienic treatment of, 325; of epilepsy, 67; the, of fevers, 95.
 Alcohol, and stomach digestion, 308; in scarlatina, 162; mortality referable to, 201.
 Alderson, Dr. M. E., poisoning from castor-beans, 719.
 Alkaloids of decomposition, 523.
 Allen, Dr. Harrison, notice of book by, 167, 496.
 Alloplasty, 232.
 Alumni Association of College of Physicians and Surgeons, 573.
 Aluminum, in the treatment of phthisis, 683.

 Thigh, new methods of reducing dislocations of, 403.
 Thomas, Dr. Frank W., 28.
 Thompson, Sir Henry, notice of book by, 440.
 Thompson, Dr. W. G., a successful case of sponge-grafting, 567.
 Thomsen's disease, 409.
 Thoracentesis, antiseptic, 432.
 Throat, inspection without instruments, 495.
 Thrombosis of the basilar artery, 432.
 Thymus, enlarged, 442.
 Thyroid, extirpation of, 523, 699.
 Thyrotomy, 610.
 Tibia, compound fracture of, 275.
 Tidy, Dr. C. M., notice of book by, 412.
 Tissue-metamorphosis, cause of, 268.
 Tobacco, consumption of, 82.
 Tongue, cold abscess of, 515; spatula, 153; under the microscope, 308.
 Tonsillotomy, 140; without hemorrhage, 666.
 Tonsils, hypertrophied, vertigo as a reflex symptom in, 93.
 Tooth in the nose, 542.
 Toronto Medical Society, 695.
 Trachea, changes induced in, by bronchocele, 523; secretion of mucus in, 69.
 Tracheotomy, in young children, 54; sequele of, 531; report of cases, 704.
 Trance in relation to sea-sickness, 248.
 Transactions of the Medical Society of the State of Pennsylvania, notice of, 440.
 Transfusion, direct from an artery to the peritoneal cavity, 599; of an alkaline solution, 93; of pure water, 351; peritoneal, 120.
 Trephine, when shall it be used in fractures of the skull? 155.
 Trephining, double identity after, 570.
 Trial by jury with reference to lunacy, 400.
 Trichina spiralis in American pork, 267.
 Trichinosis, 39, 685.
 Trichlorophenol, 60.
 Tricuspid stenosis, 68.
 Trudeau, Dr. E. L., clinical indications for couvalleria, 251.
 Tubercle, bacillus of, 26, 397; bacillus not demonstrable by the ordinary method of staining, 645; prognostic value of the bacillus, 9.
 Tuberculosis, antisepsis of, 278; secondary to syphilis, 526; general in a child, 303; in infants, 508; intimate nature of, 246; primary of the intestines, 404; prophylaxis of, 10; the pseudo-bacillus, 298.
 Tumor, cardiac, 39; of the cerebellum, 342; gummy, 39; of the pharynx, 612; pathogenesis of secondary, 246; vascular, treated without operation, 432.
 Turpentine and iodoform, inhalations of spray of, 292.
 Tympanites, cause of hysterical, 542.
 Typhilitis, 553.
 Tyson, Dr. James, notice of book by, 299.
- U
- Ulcers, bismuth in, 599; laryngeal, and iodoform, 381; of the stomach in a child, 93; tubercular of the colon, 557; varicose, 208.
 Ulna, fracture of, 661.
 Urticaria, chronic, 152.
 Uremia, 479; temperature in, 558.
 Urea as an antiperiodic, 403.
 Ureter, 385; catheterizing the female, 444.
 Urethra, stricture of, 500, 512, 662, 679.
 Urethral calculi, 132.
 Urine, albumen in picric acid, test for, 193; bacillus tuberculosis in, 321; cystine in, 321; effect upon the flow of by ether narcosis, 386.
 Uterus, ante-flexion of, 469; acute ante-flexion of, 38; ante-partum hour-glass constriction, 278; carcinoma of the fundus, 77; cancer of the neck of, 191; chronic catarrh of, 674, 691; constitutional treatment of chronic disease of, 489; disease of, in the insane, 280; displacement of, 233; displacement of, pathology and treatment of, 11; erosion of the cervix, 141; fibro-cystic tumor of, 38; gravel, puncture of during ovariectomy, 124; hemorrhage from chronic hyperæmia, 144; impregnation of a prolapsed, 701; laceration of the cervix, 143; movements of, 266; injection of, 273; osteo-fibroma, 499; prolonged menstrual flow from pinhole external os, 144; super involution of, 162; tolerance of traumatic and septic influences, 9; unicornis, 499.
- V
- Van Buren, William Holme, M.D., LL.D., obituary, 361.
 Van Santvoord, Dr. R., the danger attending the use of ether as an anæsthetic in cases of Bright's disease, 201.
 Vander Poel, Dr. John, a case of wandering needles, 587.
 Vaccina and syphilis, 323.
 Vaccination, 396, 616, 660, 677; among immigrant babies, 625; and small-pox in Hayti, 56; death from, 568; paralysis of the arm following, 569.

Vaccine, reliable virus, 656; wearing out of the protection of, 520.
 Vagus neurosis, convallaria in, 133; results of section of the, in sheep, 418.
 Vaporizer and insufflator, 361.
 Varicocele, 634.
 Variola, 337, 365, 394.
 Vein, jugular, capacity for distention, 525; umbilical, thrombosis of, 527.
 Veins, negative pulse of, 170; pulsation of, diagnostic significance of, 517.
 Venereal warts, 276.
 Venereal, protection of college students from, 211, 277.
 Venesection, to prevent premature birth, 323.
 Veratria, antagonism between, and potassium salts, 180.
 Vertebrae, removal of carious portions of, 488.
 Vertigo, laryngeal, 576; symptom in enlarged tonsils, 93.

THE FIXATIVE POWER OF TRACTION IN THE TREATMENT OF HIP DISEASE.

By A. B. JUDSON, M.D.,

ORTHOPEDIC SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

THAT traction possesses to a certain degree the power of fixing the joints of the extremities is not a new idea in surgery. It was entertained in the last century by Desault, whose apparatus for fracture of the femur is described as follows: "This consists, to speak in general terms, in taking the points of extension above, on the tuberosity of the os ischium of the diseased side, and below, on the malleoli; in securing the straps or rollers, destined for making extension, on the two ends of a strong splint, placed along the outside of the limb; and in converting, so to speak, the pelvis, the thigh, the leg, and the foot, into one entire and solid piece."¹ In 1835 Lesauvage wrote that one of the objects of continued extension in the treatment of hip disease is to prevent motion.² Mr. Liston, seeking to disparage the use of the weight and pulley in the treatment of hip disease, said: "All this may amuse the patient's mind, perhaps, but I do not think any good can come of it further than preventing motion."³ M. Philipeaux writes, "that in the absence of retentive splints, traction may be employed to secure immobility of the limb."⁴ Dr. C. Fayette Taylor refers to "the quiet fixation of the joint, which the splint has been a convenient means of accomplishing."⁵ Dr. Louis Bauer says: "Whatever benefit I have derived from it (extension) is unquestionably due to its collateral effect upon fixing the affected articulation."⁶ Mr. Thomas, referring to extension, writes: "In its application it involves, unavoidably, a fractional degree of fixation."⁷ Dr. L. M. Yale writes: "When the muscular spasm is urgent, fixation cannot be secured, save by the use of a force as constantly acting as that which is to be overcome, and the agent best adapted to this purpose is traction."⁸ Dr. J. A. Wyeth writes: "Extension is made by means of the screw-key, until there is freedom from pain and a comfortable fixation of the limb."⁹ Dr. N. M. Shaffer writes: "When traction exists the patient has the advantage of that peculiar and perfect immobility which the extension of the long hip splint affords."¹⁰

The fixation of the hip-joint is one of the most difficult problems in mechanical surgery.¹¹ In the first place, this articulation is a ball and socket. Aside from this

the difficulty is due, in a great measure, to the fact that the hip-joint is situated near the centre of the body. In order to understand the subject clearly, it may be well to take an elementary view of the relation of the muscles to the joints, as follows: The muscular apparatus of a joint has a twofold function. It can at will either move or fix the joint. If the joint be remote from the centre, the muscles will be more effective in their control either for motion or fixation, because of the disproportion in size and weight between the part above and that below the point of motion. There is philosophy as well as humor in Dundreary's witticism: "Why does a dog waggle his tail?" Answer. "Because the tail can't waggle the dog."¹² As the wagging of a dog's tail is not only motion alternately right and left, but also arrest of motion right and left, it is clear that motion and fixation, as effects of muscular action, are correlative, and if the part below the point of motion is more easily moved on account of its comparative lightness, it will also be more easily fixed, and if more easily fixed, disease attacking the joint will be less serious and more easily curable. In this lies a partial explanation of the fact that joint diseases of the lower extremity become less serious as we pass from the hip toward the phalanges. Aside from the fact that the hip-joint has a peculiarly wide range of movement, if the entire limb were no larger and heavier than the foot, hip disease would not be more serious than ankle disease. A striking illustration of this point is the case related by Mr. Hilton,¹³ in which the patient had disease of the left knee and the left hip. Amputation, which was performed above the knee, promoted recovery at the hip by facilitating the control of the latter joint by muscular action. To quote Mr. Hilton's words: "In fact, I may say the hip-joint was cured by cutting off the leg."

Furthermore, a joint which is situated near the centre of the body is peculiarly liable to be disturbed by the movements of other members. The distal phalangeal joint is not appreciably affected by movements made elsewhere, but the hip-joint is inevitably disturbed by the movements of other parts of the body. In the words of Sir Charles Bell: "There is no rest to it; every motion of the body may be said to be accompanied with a movement of the head of the femur within its socket; even if the arm be raised, there is a change in the centre of gravity of the body, and the trunk must be poised anew upon the hip, as the centre of all our motions. It is remarkable how the slightest degree of movement in another part of the body is, as it were, necessarily accompanied with a motion of the surfaces of those bones which compose the hip-joint. If ever you should see a patient suffering with acute inflammation of the hip, you will see the proof of this; for every motion of the body gives extreme pain, and proves an additional source of excitement and inflammation. It is this consideration which leads us to understand the difficulty of curing the disease."¹⁴

Another most serious obstacle to the successful fixation of the hip-joint is found in the fact that a retentive splint acts here at a great mechanical disadvantage. If the distance from the acetabulum to the crest of the ilium were equal to that from the head of

¹⁰ Archives of Medicine, p. 108. October, 1880. The opinion has been expressed by the present writer that "traction, however applied, is unavoidably accompanied by fixation," that "the advantages derived from the traction exerted by the hip splint are due solely to the fact that it secures fixation," and that "fixation is undoubtedly one of the principal functions of the long hip splint." New York Medical Journal, p. 17. July, 1882. St. Louis Courier of Medicine, p. 370. May, 1881.

¹¹ THE MEDICAL RECORD, p. 738. June 26, 1880.

¹² In 1828 Sir Charles Bell said: "No instrument has ever been effectual in keeping the thigh and trunk fixed." London Medical Gazette, p. 139. January 12, 1828.

¹⁵ Loc. cit., p. 138.

the femur to the condyles, or if, in imagination, we were to convert the pelvis and the vertebrae into a single bone, a retentive splint would doubtless be as effective in securing fixation as it is when used at the knee, or when applied to a fracture in the middle of the shaft of a long bone.¹

In view of these difficulties, can we reasonably hope to secure fixation of this joint by so simple a method as traction? That this expectation is not entirely unreasonable, is indicated by the fact that the most remarkable result of the application of purely fixative apparatus, viz., the relief of pain, is also the result of the application of apparatus that is purely tractive. The following observations prove the anodyne quality of the simple retentive apparatus. Dr. Coates, referring to the use of Dr. Physick's hollow carved wooden splint, which extended from the external malleolus to the middle of the thorax and embraced nearly one-half of the trunk, wrote: "The patient frequently stated that he had obtained, in the night following its application, sounder sleep than for many weeks or even months previously."² M. Bonnet, referring to *le grand appareil*, which embraced two-thirds of the circumference of the lower limbs and the lower part of the trunk, wrote: "I have seen the pain and inflammation disappear as soon as the limb was brought into position and held immovable." Relating a case, he wrote: "From the moment of application the pains diminished."³ M. Philipeaux, referring to a case in which Bonnet's apparatus was applied, wrote: "The next morning I learned that the patient, who had moaned incessantly the night preceding the application, had slept calmly for four hours."⁴ Mr. E. J. Chance's splint embraces the thigh and a large part of the trunk, and Mr. E. Noble Smith speaks of "the almost immediate relief from pain which the patient experiences when the splint is applied."⁵

On the other hand, the anodyne effect of simple traction is equally remarkable. It was observed by M. Blandin that on the application of extension and traction the acute pains of hip disease "disappear as if by enchantment."⁶ Gustav Ross said that when the weight and pulley were used in the hip disease of children, "the pain lessens astonishingly."⁷ Dr. John Watson, describing his treatment of a patient in the acute stage of hip disease, said: "I had hardly put on the counter-extension before the girl was entirely free from pain. It operated beautifully and instantly."⁸ Dr. E. S. Cooper, referring to his ingenious device for traction and counter-traction, writes: "Often have patients slept better the first night after its application than they had for many months previously."⁹

When we find, as above, that pain is controlled equally by direct fixation and by traction, can we escape the suggestion that perhaps traction is in itself an effective method of securing fixation? It has been stated as an objection to this view, that the relief which follows traction is too instantaneous to be considered as the result of fixation. It is thought to occur before immobilization could have produced any effect. In reply it may be said that the pain of hip disease is composed, to a certain degree, of extreme apprehension and mental and muscular fatigue, produced by prolonged efforts to prevent motion, with sudden sharp accessions when motion is inadvertently made, or when the patient starts in the act of falling to sleep. Such pain as this is capable of

instant relief or abatement by fixation. In certain cases there is a severe pain not controlled by mechanical treatment, the occurrence of which, sometimes at least, accompanies the development of an abscess.

We have seen above that fixation has, by a number of writers, been recognized as an accompaniment of traction applied to the hip-joint. We have also seen that clinical observation renders it not improbable that traction acts as a fixative power, because its first effect is identical with that of apparatus which is purely fixative. The important question arises whether it is demonstrable that traction secures fixation. This question may be answered affirmatively. Take two rods of iron or soft steel, of sufficient length, and form an eye in the end of each by bending its extremity into a small circle. When the rods are joined by these eyes they will together resemble two links detached from a surveyor's chain, and there will be wide and free mobility at the joint. Then tie the free end of one link to a staple and apply moderate traction, by means of a weight and pulley, to the free end of the other. It is seen at once that the mobility which existed at the joint between the links is absent so long as the traction continues.¹⁰ Although the immobility thus produced is liable to be overcome by a competent disturbing force, it is nevertheless quite sufficient to relieve the pain of hip disease and to promote union in fracture of the long bones. But in the treatment of hip disease fixation by the weight and pulley is open to the objection that it necessitates prolonged recumbency, and is liable to wilful disturbance. Discarding for these reasons the weight and pulley, let us subject the two links of surveyor's chain to traction in a hip splint, tying the free end of one to the perineal straps and that of the other to the leather strap which leads to the foot-piece. The result of applying moderate traction by the rack and pinion when the parts are thus arranged is fixation of a remarkably stable and indestructible kind.

It is worthy of note, furthermore, that when the hip splint is applied to a patient traction is made in such a manner that fixation is rendered more complete by a part of the apparatus which acts as a brake. The hip splint is so well known that it does not require a description here. It is sufficient to say that the apparatus here referred to has a less flexible upright and pelvic band than have been found in some forms of the apparatus, and also a bolt and nut connecting the two parts, by the use of which they can be firmly fixed at any angle desired by the surgeon. It is provided with suspending straps passing over the shoulders, by which the adhesive plasters and the affected limb are relieved from the weight of the splint when raised in walking. It also has a U-shaped attachment¹¹ at the level of the lower part of the thigh, by which motion is more fully arrested than by a flexible strap.¹² The parts which act as a brake are the perineal straps. A brake is described as follows: "An apparatus used for retarding the motion of a wheel by friction on its periphery." As applied to a patient, the hip splint, when traction is exerted, makes friction on the tuberosities of the ischia and the rami of the ischia and pubes, these parts representing the periphery of a wheel revolving at the upper end of the femur

¹ One of the difficulties in the treatment of Colles's fracture of the radius arises from the shortness of the lower fragment. If this fragment, the caput, the metacarpus, and the phalanges, were one piece the management of the accident would be greatly simplified.

⁹ *San Francisco Medical Press*, p. 145. July 15, 1861. Dr. James A. Post has

noted the remarkable relief afforded by the weight and pulley in cases of hip disease in an adult (*Philadelphia Medical News*, p. 527, November 11, 1882).

¹⁰ In this way we arrive at a competent explanation of the efficacy of traction by the weight and pulley in the treatment of fractures, a method the antiquity of which has been traced by Mr. J. H. James (*Address in Surgery*, Transactions of the Provincial Medical and Surgical Association, vol. viii., pp. 213-216, 1846) and A. S. Golner (*Nouvel appareil pour le traitement des fractures du col du fémur*, p. 30. Paris, 1835). The explanation which depends on the supposition that traction places the muscles on the stretch and thus makes them retentive splints is open to the objection that traction is powerless to stretch the muscles to a degree even approaching the normal lengthening to which they are accustomed in the ordinary movements of the limb. If a muscle is in extreme normal contraction, its opponents are of course relaxed and lengthened, and when the parts are at rest this potential elongation is so great that traction would be incompetent to stretch the muscles enclosing a long bone in any degree, still less to give them enough tension to qualify them for the functions of a retentive apparatus. For the same reason the efficacy of traction (continuous extension) in the treatment of fractures can hardly be said to depend on its ability to tire out the muscles whose contraction produces displacement of the fragments.

¹¹ Described in *The Medical Record*, p. 738, June 26, 1880.

¹² Some practical points in the management of this apparatus have been considered in the *Medical Gazette*, pp. 413-415, December 10, 1881.

through a considerable arc in the plane of flexion and extension. If friction can be made on the periphery of this wheel by a process or offshoot of the femur, motion of the pelvis on the femur (or of the femur on the pelvis) will be retarded or prevented. The perineal straps are a process of the femur inasmuch as they are carried by the pelvic band, which is immovably attached to the upright, and this latter is practically of one piece with the femur, especially if the femur is held parallel with the upright by the U-shaped piece attached at the level of the lower part of the thigh. In the accompanying figure let the circle represent the pelvis, A the acetabulum, A B the femur and the upright, and C D the perineal straps, practically of one piece with A B and applied to the ischiatic tuberosities. When traction is made by the rack and pinion, it is clear that motion at A will be retarded or prevented. In practice it is found that when traction is made, in the case of a patient to whom the hip splint is applied, motion in flexion and extension is prevented, although it may not as yet have been arrested by the disease.

Motion in adduction and abduction is also arrested to a certain degree by this apparatus—adduction by the circumstance that, as the perineal straps are both situated on the inner side of the joint, traction is abductive or in a direction away from the median line; while motion in abduction is opposed by the action of the apparatus as a retentive splint (although its action as such is feeble), applied to the outer side of the limb and pelvis, the retentive force being directed from within outward at the upper part of the thigh, and from without inward at the pelvis and the lower part of the limb.

The question here arises, whether an apparatus so well contrived for the arrest of motion in the hip-joint could not be used with advantage in appropriate cases in the treatment of fracture of the femur, a question worthy of attention because the hip splint not only secures fixation but also permits the patient to walk, a point of importance in the management of ununited fracture. It may also prove to be useful after osteotomy for deformity of the hip.

The idea that hip disease requires the same treatment as fracture of the femur is not new in medical literature.¹ M. Bonnet presented *le grand appareil* for the treatment of hip disease in 1845, although he had described it in all its details in 1839, as an apparatus for the treatment of fractured femur.²

In the same manner, but with a longer intervening lapse of time, the complicated apparatus of M. Martin was prescribed by him in 1850 for fracture of the femur, and in 1865 for hip disease.³ Mr. Ford compared hip disease without an external opening to a simple fracture of the bone,⁴ and Sir Benjamin Brodie carried the comparison further, saying: "If it (the cartilage) be extensively destroyed without suppuration, the case may be compared to one of simple fracture; and if there be suppuration, it may be compared to one of compound fracture;" a statement which drew from Dr. Alden March this apt inquiry: "If there be some analogy between the condition of the hip-joint in morbus coxarius, and fracture

of the neck of the bone, why should there not be some similarity in the mode of treatment?"⁵

If we recall the morbid anatomy of this disease, in which the integrity of the central portion of the bone is invariably assailed, we can better understand the comparison of hip disease to a fracture of the bone, and the more readily recognize the propriety of treating it by fixation. If hip disease were synovitis, invading, under the pressure of reflex muscular contraction, first the cartilage and then the bony tissue, it would be right to try to diminish this pressure by traction, or any other method believed to be practicable.⁷ We might even attempt the difficult combination of traction with mobility, in the hope that motion without friction would perhaps assist the process of repair and secure a recovery without impairment of mobility. But the disease is not synovitis. It is osteitis, beginning in the cancellous tissue, or at the epiphysal junction, excavating the bone, undermining its strength, progressing from within outward, and involving in time all the structures of the joint. In this view it is clear that the proper local treatment is protection from the pressure and concussion incident to walking, and the prevention of motion in the joint. As in a fracture, so in hip disease, the part should be placed in a favorable position for the action of the natural reparative processes which, aided by appropriate general treatment, are, as a rule, able to limit this morbid process when it occurs in parts which, like the ankle, are more easily protected from disturbance and violence by the voluntary efforts of the patient.⁸

It may be said, in criticism of this precept, that the intention in treating a fracture is to abolish mobility, which, in a case of hip disease, it is our desire to retain or recall. In reply, it may be well to state that the cases of real hip disease which recover with perfect motion in the joint itself are rare, no matter what form of treatment or expectancy be pursued. There are, indeed, many cases in which the friends of the patient erroneously believe that motion of the joint has been preserved, basing their opinion on the evident facility with which the patient walks. It is a common idea among non-medical observers that the limb cannot assist in locomotion if there is absence of motion at the hip-joint, while the truth is, that with a perfectly motionless hip-joint walking may be very well performed, and even with considerable grace, by reason of the acquired mobility of the lumbar region of the spinal column, and by the patient's unconsciously taking advantage of the motion of the unaffected hip.⁹

It is not unreasonable, however, to suppose that central osteitis occurring so near the joint as to produce all the symptoms of incipient hip disease, may, in favorable conditions and with treatment commenced sufficiently early, be resolved with perfect motion in the joint. Such cases have been observed. Patients have even been observed to recover from the third stage, with considerable useful motion in the joint. In every case, therefore, whether the disease be recent or in the third stage, the surgeon should try to secure recovery with motion, and it is important to observe that the treatment herein described not only prevents ankylosis, if it can be pre-

⁶ Transactions of the American Medical Association, p. 503, 1853.

⁷ The pathological objections to this view have been presented in the New York Medical Journal, pp. 1-17, July, 1882; the mechanical objections in THE MEDICAL RECORD, pp. 509-512, May 12, 1883.

⁸ Remarkable results from expectant treatment in disease of the ankle have been obtained by Dr. James Knight, at the Hospital for the Ruptured and Crippled. Thirty cases have been reported by Dr. T. E. Satterthwaite (Report of the Surgical Committee of the Therapeutical Society, MEDICAL RECORD, pp. 197-202, August 21, 1880) and Dr. V. P. Gibney (Cases of the Ankle in Children, American Journal of Obstetrics, pp. 434-457, April, 1880). These results have not met the appreciation which they deserve. Dr. Gibney writes (op. cit., p. 451) that in ankle disease excision "is rarely ever justifiable." He adds: "The expectant plan of treatment, fully carried out, assures us of more results that are perfect, and more limbs that are useful without the aid of support, than does any other plan known to the profession." These words give appropriate expression to a conservatism closely allied to that which crowns with honor the memory of Fergusson.

⁹ Mr. Hilton describes one of his patients, who recovered with a firmly ankylosed hip-joint, as follows: "She is an excellent dancer, frequently dancing for a whole evening, and but few persons know, when she sits down, that the right knee-joint is bent at right angles with the thigh and body, and tucked under the chair to meet the inconvenience of her fixed hip-joint." John Hilton: Rest and Pain, p. 373. London, 1863. American Edition, p. 221, 1879.

¹ In 1779 David de Rouen, referring to diseases of the joints, wrote that notable cures are to be effected "by allowing the parts to remain undisturbed in splints, as in the treatment of fractures." R. Philipeaux: De la Coxalgie, p. 381. Paris, 1867.

² Mémoire sur les fractures du fémur, Gazette Méd. de Paris, pp. 570, 580, September 14, 1839. Traité des maladies des articulations, vol. I., pp. 322-324. Lyon, 1845.

vented, by subduing inflammation, but also, if ankylosis be inevitable, provides for the best position of the limb.

The fixation which this apparatus secures is of a peculiar quality. It may be compared to the condition found in some forms of paralysis, when a joint is said to resemble a leaden pipe, which may be bent with suitable force, but retains with sufficient firmness whatever position it may be placed in. This "fractional degree of fixation" is attended with sufficient arrest of motion to allay inflammation, encourage the reparative process, and afford relief from pain; and yet it is not so inflexible as to prevent the gradual correction of the deformity in obedience to the unconscious efforts of the patient to place the limb in its most useful position, which is that of slight flexion with neither adduction nor abduction. This position permits both walking and sitting with considerable facility, although the joint be motionless.

The deportment of the limb under this treatment is observed to advantage in a case that has progressed so far that the patient is confined to his bed while the thigh is in excessive flexion and adduction, and yet not so far that the structurally shortened muscles are an impediment to the reduction of deformity. Almost immediately the adduction is visibly lessened, and is succeeded in a few days by abduction, which in its turn becomes excessive, because the direction of the traction is abductive or away from the median line. But when the patient has gathered strength from the relief of pain and the ability to sleep, which are secured by fixation, and begins to walk with the assistance of the ischiatic crutch¹ furnished by the perineal straps, and with the aid of a high sole on the shoe of the unaffected side, it is seen that the abduction is, in its turn, gradually diminishing; and as the patient resumes active locomotion, still wearing the splint, the limb assumes a position neither adducted nor abducted, in which it is most favorably situated for walking.² And while the limb has been making these changes laterally, it will at the same time be reduced from a position of extreme to one of moderate flexion, in which it is most favorably situated for both walking and sitting. The favorable position thus acquired is retained without difficulty until recovery is assured.

TWO CASES OF INCOMPLETE FRACTURE OF THE FOREARM.

By GUY HINSDALE, M.D.,

HOUSE SURGEON IN THE EPISCOPAL HOSPITAL, PHILADELPHIA, PA.

DURING a service of four months in the surgical dispensary of the Episcopal Hospital, nearly fifteen hundred new cases presented themselves. Among these were five incomplete or "green-stick" fractures of both bones of the forearm, one of the radius alone, and one of the clavicle. The patients were all children from one to six years old, excepting two, whose history I will give.

CASE I.—Frank B. T., aged thirteen, came to the dispensary July 8, 1882. While standing upon a wooden

stool about eighteen inches high, the legs of which were loose, he fell upon a hard cellar floor. He had been reaching high up, holding his left arm in full extension. In his fall his forearm fell across one of the legs of the overturned stool, striking upon its posterior surface and producing the deformity as figured. Although partly

stunned by the fall, he noticed his arm resting on the leg of the stool.

Upon presenting himself at the dispensary within half an hour after the accident he did not exhibit great suffering. The bones were bent backward at their lower fifth; the hand and wrist were not greatly swollen, and motion at the wrist-joint was good. The deformity was so marked that before reduction was attempted I obtained the contour of the limb by means of lead ribbon and took the following measurements, the forearm being flexed at a right angle with the arm and pronated: External condyle of humerus to styloid process of ulna, $8\frac{1}{2}$ inches; external condyle of humerus to styloid process of radius, $8\frac{3}{4}$ inches.

Mobility and crepitus could not be obtained and the diagnosis of incomplete fracture was made. By means of extension and counter-extension and manipulation the bones were at once restored to their original form. As they became straight snapping of fibres of bone was distinctly heard and felt, but complete fracture did not take place. The forearm was then enveloped in lint soaked in lead-water and laudanum, and straight splints were applied to its anterior and posterior surfaces. The wet dressing was continued a few days until the pain and swelling, which was slight, had subsided.

At the end of the third week the splints were removed and a piece of binders' board was moulded to the anterior surface of the arm. There was still some tenderness at the ulnar side of the seat of injury. The measurements made in the same manner as before were now 9 inches and $9\frac{1}{4}$ inches. The patient was discharged at the end of the fifth week. Two months later a similar accident befel him, occasioning almost precisely the same condition as described above, and requiring the same treatment.

CASE II.—Esther S., aged sixteen, a weaver, applied on June 9, 1882. While standing in the mill near her loom, for an instant she rested the elbow of her right arm against the wall, her hand being fully extended. She was instantly struck a sharp, hard blow upon the ball of the hand by the flying shuttle-box, which forced the hand and arm backward toward the wall. The patient was seen about an hour after the accident and found to be suffering greatly. Both bones at the lower fifth were bent backward; the hand was flexed and both it and the wrist were somewhat swollen and of rather a dusky hue. The gentlest touch gave rise to such pain that at the patient's request I asked an assistant to administer ether.

The forearm being flexed at 90° and pronated, the distance from the external condyle of the humerus to the styloid process of the ulna was found to be $8\frac{1}{2}$ inches. Grasping the forearm near the elbow I then made traction from the wrist. Both bones were firm, neither crepitus nor mobility could be obtained. The deformity was then reduced by grasping the forearm with the left hand, the wrist with the right, and making pressure with the thumbs upon the posterior surface of the arm over the seat of injury. As the bones assumed their proper shape the snapping of their fibres could be distinctly felt and heard. With a great deal of force and firm and gradual pressure, and by placing the arm upon a plane surface and pressing forcibly over the seat of injury, the bones were restored to a straight line. It was quite easy to feel the bony fibres give way, although complete fracture did not take place. The arm was then dressed with lead-water and laudanum and placed on a straight, broad palmar splint, reaching from the olecranon to the finger-tips; after applying compresses at the seat of injury, upon the ulnar and dorsal surfaces, a bandage was applied. Wet dressings were discontinued after a few days and a shorter splint substituted. This was laid aside in about four weeks from the time of accident, and the patient ordered to rub the arm well with soap liniment.

Five weeks after the accident the arm looked and felt almost precisely like its fellow, but by passing the hand along the ulna at about the lower fifth a small ridge of callus could be felt. Measurement was again made in

¹ The question of axillary or ischiatic support has been considered in THE MEDICAL RECORD, pp. 1-3, July 2, 1881.

² Cases treated in this manner, in the third stage, have been reported in the Illustrated Quarterly of Medicine and Surgery, pp. 47-52, April, 1882.

the same manner as before and found to be $9\frac{1}{4}$ inches. No tenderness over the seat of injury. The accompanying cut illustrates the deformity:

In most of the works on surgery very little is said upon the subject of bent and incomplete fractures. The works of Gross¹ and Hamilton,² and an article by John Rhea Barton,³ contain the most satisfactory references.

In young children it is possible for bending of bones to take place without perceptible rupture of the bony fibres; the outline is curved, while incomplete fracture in older children usually presents an angular deformity. These curving bones yield more easily to pressure and even of themselves show a tendency to resume their proper shape; incomplete fractures, however, are usually restored with difficulty. As for impacted fractures in the forearm, they usually occur in adults, and by an examination of the bones the rough line of the fragments can almost always be recognized. Efforts to elicit crepitus are, in all these cases, unsuccessful.

As for the treatment in very young children spontaneous recovery may occur. It is, however, better to secure the proper outline by firm, gradual pressure, and the application of splints. Complete fracture may occur in the effort to reduce the deformity and need not excite alarm. The case is then transformed to one of simple fracture. But as this accident destroys the continuity of the bone, and is apt to be followed by a certain deformity, it should, if possible, be avoided.

In regard to the cause of incomplete fracture the prevailing impression has been that it is due to differences in the proportion of the organic to inorganic elements of bone at the different periods of life. Gray¹ quotes Schreger and Rees, who state that the proportion of the earthy element increases with age, and Stark¹ and Von Bibra, who state that the proportion is constant. The later analyses of Mr. R. Tuson,² Demonstrator of Chemistry at St. Bartholomew's Hospital, confirm this statement. The analysis was made of equal weights of long bones of different ages, viz.:

	At birth.	10 years.	36 years.	71 years.
Organic matter.....	35.37	32.62	32.04	32.94
Inorganic matter.....	64.63	67.38	67.96	67.06
	100.00	100.00	100.00	100.00

The predisposition of young bones to incomplete fracture must therefore be sought for in physical rather than in chemical differences. Young bones have a more spongy texture. The proportion of the compact to the cancellous element is smaller in the young than in the old. The specific gravity is also less. To determine this I took two radii. One was from a child about ten years of age, and was itself a fine illustration of incomplete fracture. Its specific gravity was 1.358; the second was from a man forty-five years of age, and its specific gravity was 1.429; while a section taken from the middle of an adult femur gave 1.600.

There is also a difference in the size and structure of the Haversian canals. As the bone grows, the lamellæ increase in number from the periphery inward until as many as fifteen rings may be counted. The calibre of

the canals is therefore larger in young subjects than it is in the aged. It is proper also to state that in growing bones the Haversian interspaces are more abundant.

It is, I believe, owing to these facts, taken collectively, that young bones are permitted to bend when an older and a denser bone would snap.

THE RELATIONSHIP BETWEEN DIPHTHERIA AND SCARLATINA.

By GEORGE T. WELCH, M.D.,

KEYPORT, N. J.

MOST medical authors are at particular pains to controvert the opinion that scarlatina may be complicated with diphtheria, and strenuously oppose the clinical experience of independent observers with an array of arguments, which might become invincible if nature could be held in bonds by any charm of words. But not even the anatomist can map so accurately that some anomaly may not arise; while the pathologist constantly discovers the confusions attending upon the invasion of one disease into the territory of another. Medicine would become an easy art indeed, and every man would be his own doctor, if but one morbid ill could dispute with life at a time; but as Mary Magdalen was possessed of seven devils, so a crew of noisy complications in some diseases puts the wits to wrangle, and disturbs the judgment. It is certainly the duty of the teachers to simplify the study of morbid processes, to lop away the traditions, thin the redundancies, and let in all the daylight possible upon our science. But to contend that one disease alone hunts in an epidemic is manifestly absurd. And the gentlemen who deny the existence of diphtheria as a complication or sequela of scarlatina, or *vice versa*, readily admit that the former complicates measles, or that it deepens the malignancy of typhoid. Where is the consistency? What is more reasonable than that diphtheria should be awakened when the system is profoundly poisoned with scarlatina, especially since the latter insidiously ravages the same membranes? How seldom does a complication arise in any malignant disease until the invasion of certain vital structures invites the disease that usually preys upon that organ?

All the older writers acknowledged a relationship between the two diseases. In fact, while diphtheria has had an authentic history of two thousand years, scarlatina was never separated from it until within these last three centuries, nor given a name until Sydenham stood sponsor in 1676. We refine upon the ancients, but disease is a gross Caliban that constantly escapes his boundaries.

Let us see how some of the best authorities differ. Says Da Costa, "Diphtheria and scarlatina are certainly allied but not identical; for the poison of one leads to a cutaneous rash, and leaves a protective influence against a second attack; but often also deafness, suppuration of the glands of the neck, and dropsy—phenomena which are not encountered in the other. Moreover the exudation is not exactly similar in the two diseases. In scarlatina it is pultaceous and not coherent, and has no tendency to spread to the respiratory passages."

It is the observation of Squire, in "Reynolds's System of Medicine," that in diphtheria, while there is no diffused redness of the skin, sometimes little isolated red spots are discovered in different parts of the surface, and that the recurrence of the disease in the same individual, if it has been once fully formed, is by no means settled conclusively in the affirmative. Further he states that the albuminuria of diphtheria occasionally results in anasarca.

Mercatus mentions a rash in some of the Spanish epidemics of diphtheria, with redness of the whole face and neck. Fothergill describes a rash in the first edition of his treatise on the disease. Aitken, treating of anginose scarlet fever, declares the sore throat may be of a diphtheritic character.

⁶ Dr. Stark: Edin. Med. & Surg. Journal, 1845.

⁷ Human Osteology, p. 3. London: Luther Holden, 1878.

Hartshorne tells us that occasionally paralysis is a sequela of scarlatina, and that the paraplegia may exist for several weeks or months. It is the opinion of Flint that in some severe cases of scarlatina anginosa the pharynx offers all the characters of diphtheritic inflammation. He observed, in consultation with Dr. Biady, of Brooklyn, a boy who had recently had diphtheria, now suffering with complete hemiplegia and general dropsy. After his convalescence his sister was attacked with scarlatina.

Professor Clark, in his lectures on Diphtheria, has given the details of a case in which that disease was held in abeyance during scarlatina and measles, these diseases following each other rapidly, when the diphtheria again appeared, and proved fatal.

Henoch, in his "Diseases of Children," vehemently denies the complication of diphtheria with scarlatina, but like an honorable observer, a page further on, records the autopsies of seven cases of scarlatina in which fibrinous infiltration of the pharynx descended to the larynx; and of two cases which showed upon post-mortem examination diphtheria of the pharynx, and in one, of the oesophagus also.

Dr. L. A. Smith presented to the Pathological Society of New York the pharynx of a child covered with true diphtheritic membrane, the little patient in life presenting characteristic symptoms of scarlatina.

To these latter I desire to add my own observations. April 30, 1882, I was called to see Frank T—, a lad of ten years of age, who had had scarlet fever in a light form two years before. He had soreness and stiffness of the throat, enlarged cervical glands, inflamed tonsils which filled the throat almost to suffocation, and with the pharynx and half-arches presented a glistening appearance as though coated with varnish. May 1st, the right tonsil had at the centre a yellowish white spot which increased gradually in size, the next day appearing on the left tonsil, and subsequently upon the uvula, velum, base of the tongue and roof of the mouth, and into the nasal passages, accompanied by symptoms of suffocation and impending dissolution dreadful to behold. May 6th, the exudation began to be detached, and by the 8th the whole of the affected portions of the throat were cleared of the diphtheritic membrane, and, despite relapses, the patient finally made a good recovery. So tenacious was this membrane that sometimes, being dislodged from the throat, it would adhere to the roof of the mouth with such persistency that the boy would find difficulty in scraping it off with his fingers. Albuminuria occurred during the progress of the disease. There were no sequelæ.

May 2d.—Joseph L—, an infant of sixteen months, in this family, was attacked with scarlet fever, the efflorescence being diffused generally over the whole surface. May 3th, the eruption subsided, when diphtheria supervened, the tonsils being rapidly covered with the tenacious exudation, which extended both upward and downward, the larynx becoming involved, and the patient dying on the 8th.

On May 6th and 7th, two other children in this family were attacked with severe scarlet fever, without special throat symptoms.

For some months subsequently isolated cases of scarlet fever would appear in families a distance from each other, and in December two cases of diphtheria occurred in a family three miles from Keyport. A child of this family, convalescing from a light attack, conveyed the disease to a little girl of three years in a neighboring family. Five persons were attacked in this family, an infant of twelve months dying from the disease. Paralysis was a sequela in two of the cases. Other attacks of diphtheria appeared in this neighborhood, and scarlatina occurred at the same time in town.

On January 22, 1883, I was called to see a son of Z— C—, aged twelve, who passed through all the stages of a mild attack of scarlet fever. On the 28th,

his two little sisters, Sarah and Grace, two and four years of age, were attacked with the fever. February 5th, Grace was prostrated with virulent symptoms of diphtheria, which extended into the nasal passages, the thin, acrid discharge from which excoriated the upper lip, and acting as a centre of infection, the whole face became involved in a revolting eczematous eruption, which was with great difficulty subdued. Complete paraplegia resulted during convalescence, the child toppling over whenever raised upon her feet, and finally dragging herself by her hands and arms in a sitting posture about the floor. She recovered completely by the end of April.

On February 5th, another sister, Annie, aged ten, was prostrated with severe scarlatina, which began to subside on the fifth day. February 12th she was attacked with diphtheria. On the 16th, false membrane of considerable density was expectorated. Regurgitation of liquids and nasal tone of voice were persistent for some time afterward. In the third week rheumatism of all the large joints occurred, and desquamation, which had been deferred, now began.

On February 11th, I visited Geo. A. F—, ten and one half years of age, who had been ill since the day before. I was struck with the intolerable fetor of his breath as soon as I entered the room. His skin was glowing with the characteristic eruption of scarlet fever. On the succeeding day the brain expended itself in a fury of active delirium. The body roasted at a dull heat. The stiffened jaws would scarcely permit an examination within, but an ash-colored, parchment-like exudation was plainly discovered. February 13th, nasal passages occluded, voice hoarse and inarticulate. February 15th, membrane began to loosen, the edges looking like the frayed finger of a leathern glove. Large pieces, still tough, having the mould of the glottis, were drawn from the throat on a sponge probang. These adhered to the skin like collodion. Upper lip excoriated. Virulent sores were grouped about the alæ of the nose. The conjunctivæ became granulated and covered with an ash-colored deposit. In the meantime the rash had not faded from the body. Death occurred on the seventh day of the disease.

February 15th.—Frank F—, aged nine, was attacked with scarlet fever, and made a good recovery, without any notable departure in the type. C—, an infant of seven months, in this family, was attacked on February 27th with diphtheria of the most malignant form, speedily investing the larynx and causing death on the fifth day. A small ulcer on the face was covered with diphtheritic deposit. The mother had a mild attack of this disease about the same time.

February 15th.—I was called to see Mrs. S. D. C—, a stout, florid lady of forty, who was almost in a state of suffocation. Voice indistinct; liquids regurgitated through the nose. An ash-colored diphtheritic membrane invaded all parts of the throat that could be seen, even extending to the base of the tongue, and upward into the nares, the neck brawny, the pulse swift, the temperature exalted. There was no hopeful presage among all the symptoms. Ice was used in abundance within and without the throat; large doses of perchloride of iron frequently exhibited in milk, though swallowed with increasing difficulty; rectal alimentation, wine, lime-water sprayed in the throat; the room filled with an atmosphere of steam. On the third day there was an evident tendency to softening of the membrane, its edges loosening and having the appearance of old wash-leather, but the patient was alarmingly near death, too. A solution of perchloride of iron was used with an atomizer in the throat, and then twisting about in the latter a sponge probang dipped in the perchloride in glycerine. To my great relief a large piece of membrane was detached. It now broke down rapidly under the use of the atomizer, and enough more was withdrawn to afford sensible relief from impending death. The patient was making a fitful and tardy recovery, when, on the tenth day my attention was called by the nurse to a

scarlet efflorescence which, by the afternoon, covered the face, neck, shoulders, arms and chest, and to a milder degree, other portions of the trunk and limbs. Desquamation occurred a few days later. There was incomplete paraplegia in the third week, which caused great stiffness in locomotion for some time after. Extensive sloughing of the uvula, with severe ulceration of the pharynx followed the loosening and disappearance of the diphtheritic membrane.

At the same time that I visited Mrs. C—, I found her eldest daughter, Lida, aged fourteen, prostrated in another room with severe scarlatina, and one week later, Annie, aged three, was attacked with the same disease.

March 14th, Nellie V—, an infant aged eighteen months, was prostrated with severe scarlatina. On the 20th the efflorescence had disappeared at my morning call, but being hastily summoned in the evening, I found alarming symptoms of diphtheria had suddenly developed. On the 21st the inflamed tonsils had nearly closed all aperture between, and a glistening membrane invaded all the parts to be seen. Successive layers of this appeared in the throat. March 25th, after a series of dark days that lengthened despair to the family, the membrane began to decay. The upper portion broke short off under the use of the probang, like a fracture of macaroni, showing three successive layers of membrane. A most fetid air arose from the mouth. Membrane was expelled from the nostrils; the excoriation of the lip was very severe. A piece of membrane, moulded to the circumference of the throat, was loosened by coughing and removed with the probang. Dr. Arrowsmith, who kindly visited the patient in the afternoon and the succeeding three days, during a short illness I had, reported that at his first visit he distinctly observed the succession of layers of membrane in the throat, and brought away moderately large pieces on the probang, the child being too exhausted to assist in relieving itself. April 4th the skin began to exfoliate. An abscess of large size developed over the larynx. Paraplegia occurred later, with seeming anaesthesia of the skin, and inability to pass urine at will. The anaesthesia was inferred from the great coolness of the skin, and the child's evident desire to be warmly wrapped and held near the fire. Though previously active in walking and running, it was not able to stand alone until May 4th. During the progress of the diseases named, I met in other families scarlatina, and in others diphtheria, which did not present any of the remarkable symptoms detailed.

These cases go far to prove a relationship between diphtheria and scarlatina, even if they do not show that there is but one disease here, preying upon life under dual names, like a villain of many aliases.

Might it not be the same disease we call scarlatina when the symptoms are mild and the efflorescence well developed? scarlatina anginosa when the eruption is obscure and the throat direfully inflamed, with pultaceous deposits on tonsils and pharynx? diphtheria when the deposit is organized and extending above and below with frightful impetuosity?

There is a tribe of Kurds in Caucasus who dare not call the devil by his right name, and so the diagnosticians labor to prove a distinction whenever a difficulty arises. But your writer of pure diagnosis, I take it, is like the lexicographer who compiles from all known sources and makes an average of opinions and judgment, and like him, is forever changing his standard where the ground is disputed, for opinions vary with their sources and judgment is not infallible.

Truly the lists are not closed here, and no man should trust to the books when nature opens to him a dreadful page which he may read as well as another.

It is to this end I have offered the foregoing clinical notes as a contribution to the further study of the identity of diphtheria and scarlatina, for I am impressed with the futility of setting up fast boundaries to these morbid processes. The action of the morbid principle

in the two diseases (if they be two diseases) is so very variable in different epidemics, and in different individuals in the same epidemic, that no reliable average can be gathered from the experience of one generation, but, like the philosophy of many other scientific problems, it must be left to some wiser future.

THE TREATMENT OF SPORADIC CHOLERA.

By J. M. FRENCH, M.D.,

MILFORD, MASS.

My note-book contains the analysis of twenty-five cases of cholera morbus, occurring during the past three years, in which three different modes of treatment were employed. The cases were of various degrees of severity, some mild and some extremely severe, but all characterized by vomiting and purging, with more or less prostration.

The first plan of treatment consisted in the administration of pepsine, bismuth, alkalies, opiates, and stimulants, by the mouth, with which was frequently combined the application of sinapisms and hot fomentations externally.

The second plan was by means of the rectal injection of starch and laudanum, thirty drops of laudanum being a medium dose; and with this were combined any measures of the first class which might seem desirable.

The third plan consisted in the hypodermic injection of the sulphate of morphia, one-fourth of a grain being the ordinary dose. It was usually unaccompanied by any other treatment.

The results can best be seen by a brief review of the cases:

CASE I.—Mrs. H. S—; September, 1880; very severe; oral and external measures entirely without avail; great prostration; fatal result feared; the rectal injection of starch and laudanum proved promptly successful, and needed but one repetition.

CASE II.—Mr. W. K—; July, 1881; moderately severe; oral remedies successful.

CASE III.—Mrs. H—; August, 1881; moderately severe; oral remedies successful.

CASE IV.—Miss A. M—; August, 1881; mild; oral remedies successful.

CASE V.—Mrs. L. R—; September, 1881; quite severe; rectal injections promptly successful.

CASE VI.—Mrs. C—; September, 1881; very severe; oral remedies ineffectual; rectal injections speedily successful.

CASE VII.—Mr. M. K—; September, 1881; moderately severe; rectal injections successful.

CASE VIII.—Mr. McC—; October, 1881; moderately severe; rectal injection retained but a short time, and required supplementing by oral and external measures, administered by the nurse, owing to my absence.

CASE IX.—Mr. A. W—; August, 1882; moderately severe; oral measures slowly successful.

CASE X.—Mrs. A. W—; August, 1882; moderately severe; oral remedies slowly successful.

CASE XI.—Mrs. O. W—; August, 1882; moderately severe; oral remedies slowly successful.

CASE XII.—Miss E. G—; August, 1882; mild; oral and external remedies successful.

CASE XIII.—Miss M. P—; August, 1882; mild; oral measures successful.

CASE XIV.—Mr. T. F—; August, 1882; very severe; rectal injection promptly successful, and no repetition needed.

CASE XV.—Mr. C. M—; August, 1882; very severe; a strong man; not seen until he was greatly prostrated—the disease not checked; hypodermic injection of one-fourth grain morphia promptly successful, and no repetition needed.

CASE XVI.—Mr. J. S—; August, 1882; moderately severe; rectal injection administered, and repeated; slowly successful; combined with oral measures.

CASE XVII.—Mr. C. C.—; August, 1882; very severe and greatly prostrated; hypodermic injection promptly successful.

CASE XVIII.—Mrs. K.—; August, 1882; severe; rectal injection rejected, repeated, and fully successful.

CASE XIX.—Mr. C. B. S.—; August, 1882; moderately severe; hypodermic injection successful.

CASE XX.—Mr. P. C.—; August, 1882; mild, because seen early; hypodermic injection promptly successful.

CASE XXI.—Mrs. C.—; August, 1882; moderate; oral measures slowly successful.

CASE XXII.—Mr. P. O'N.—; August, 1882; sudden and severe attack, with great prostration: being close at hand, I gave a hypodermic injection, and prescribed strict quiet, as in other cases; promptly successful, no other treatment needed.

CASE XXIII.—Mrs. G. F.—; September, 1882; moderate oral measures failed; hypodermic injections promptly successful.

CASE XXIV.—Mr. G. V.—; September, 1882; quite severe; hypodermic injection promptly successful.

CASE XXV.—Mrs. F.—; October, 1882; severe and exhausting, requiring constant care; hypodermic measures and all opiates refrained from, on account of previous ill effects of morphia; oral and external measures slowly successful.

Summary.—Mild cases, 4; moderately severe, 12; very severe, 9. Cases treated by oral and external measures only, 10; by rectal injections, 8; by hypodermic injections, 7.

Conclusions.—The first plan of treatment is only adapted to mild and moderate cases, or those which have safely passed the acute stage, as in severe cases no medicine can be retained on the stomach. At best, this plan requires constant watching, and failures are frequent.

The second plan is much more effective, but is liable to need several repetitions on account of inability to retain the injection until absorbed. If not promptly successful patients are apt to lose faith in it, and often object to its repetition. Hence, it is not fully satisfactory.

The third plan is speedy, certain, satisfactory. Except in those cases where all opiates are dangerous, it is also perfectly safe if properly administered. Very seldom does it need repetition. If taken early, it is the only treatment needed. On the whole, I consider the hypodermic injection of morphia as nearly a specific for cholera morbus as anything in medicine.

PUERPERAL ECLAMPSIA.—Dr. Burton, in the *Medical Press and Circular*, May 30, 1883, says: 1. That puerperal eclampsia is a motor neurosis associated with loss of consciousness. 2. That it stands in intimate relationship to the convulsions of childhood and to epilepsy. 3. That only one factor in its production is constant, viz., a peculiar condition of the nervous system that may be designated as one of "unstable equilibrium," and that this factor is common also to the convulsions of childhood and to epilepsy. 4. That retention of urinary constituents when present vastly increases the tendency to convulsions in pregnancy, but that outside the conditions of pregnancy and childhood such retention is but rarely the cause of convulsions. 5. That nerve-irritation—shock, emotion, violent pain, uræmic or other morbid condition of blood, etc.—is capable of setting up sudden vasomotor spasm of cerebral blood-vessels. 6. That this spasm of blood-vessels, causing sudden anemia of the brain, is the cause of the convulsions and of the consequent coma. This view of the etiology of puerperal convulsions leads naturally to the treatment, and in fact furnishes an explanation of the success that has attended the employment of chloroform, ether, chloral, bromide of potassium, subcutaneous injection of morphia, and blood-letting.

Reports of Hospitals.

ST. LUKE'S HOSPITAL, NEW YORK.

(Reported by HENRY MOFFAT, M.D., House Physician.)

A CASE OF DIABETIC COMA WITH ACETONÆMIA.

So much has been written of late in the various medical periodicals upon the pathology and clinical history of this somewhat unusual condition, and so little can be found in explanation of it in the standard works on practice that I have been led to think that a case as typical as the following will not be without interest to the profession at large.

As condensed from my notes the case is as follows: George A. C.—, aged nine years, admitted September 9, 1882. Family history negative. Patient was perfectly well till January, 1882, when it was first noticed that he had nocturnal incontinence of urine. At the same time the daily quantity of urine passed began to increase. This increase became gradually more and more marked, his appetite became ravenous, thirst unquenchable, and he soon developed all the well-marked constitutional symptoms of diabetes mellitus.

On admission he was anæmic and emaciated. Upon his forehead was the cicatrix of a wound received when about two years of age. (No history of any cerebral symptoms following this wound.) He was passing one hundred and eighty ounces of urine daily. Examination showed specific gravity 1.044, acid. No albumen and no casts. Sugar, thirty-two grains to the ounce.

Patient was put upon diabetic diet, and treated with strychnia sulph. gr. $\frac{1}{100}$, and later with the bromides. Under the latter treatment he seemed to be gradually improving, and by January 28, 1883, was passing only sixty ounces of urine, with seventeen grains of sugar to the ounce.

February 11th.—Without any known cause patient began to complain of pain in abdomen, and soon became drowsy and sleepy, and when seen at 6.30 A.M. his respiration was rapid but deep; pulse rapid and somewhat feeble. He could be roused, and spoke continually of his abdominal pain. 9.30 A.M.: Pulse, 146; respiration, 36; temperature, 99°. Surface warm and dry; pupils normal and react to light; no cyanosis; patient completely comatose; the respiration was very deep and full, the whole chest expanding well.

Examination of urine passed at this time—specific gravity 1.034; acid; trace of albumen; sugar, 3.45 grains to the ounce. With ferric chloride it gave the dark wine-colored reaction supposed to be due to the presence of "acetone." At 11 A.M. patient was seen by the attending physician, Dr. G. G. Wheelock, and the diagnosis of acetonæmia confirmed.

Patient remained in this condition for twenty-six hours, when he died. There were no distinct convulsions, but just before death a slight twitching of the hands and face.

At the autopsy, performed by Dr. F. Ferguson, nothing abnormal could be detected by the naked eye either in the brain, spinal cord, or any of the viscera.

Since then, however, the doctor has very kindly furnished me with the following microscopical report:

"The kidneys are slightly anæmic—the epithelium lining the tubules in the cortex is cloudy, fatty in places. There are a large number of fatty emboli in the vessels of the kidney extending into the capillaries of some of the Malpighian tufts. There are numerous fatty emboli in the vessels of the lungs. The lungs in other respects are normal. There is a very small amount of fat in the liver, evenly diffused throughout the organ and pigment of the hepatic cells around the central vessels. The heart-fibre contains considerable pigment—the organ in other respects normal."

Upon reviewing the case there are a few points I would wish to emphasize.

1. The coma occurred in a case which was *not* acute, but seemingly improving in every way. In this it differs from the case observed by Drs. Foster and Sandby,¹ who conclude that this condition is more apt to occur in acute cases.

2. There was a marked diminution in the amount of sugar in the urine during the coma.

3. The discovery by Dr. Furguson of fat emboli in the vessels of the kidney and lungs is of interest as bearing upon the mooted question of the lipæmic origin of the coma. There was, however, no evidence of marked pulmonary obstruction, nor any congestion of the meninges or substance of the brain. (See *Edinburgh Medical Journal*, September, 1882.)

4. We cannot close without referring to the peculiarity of the respiration. When once seen it can never be mistaken. It was rapid but very deep; the whole chest being fully expanded, but seemingly no relief to the dyspnoea.

Progress of Medical Science.

A CASE OF MOVABLE KIDNEY FIXED BY OPERATION.—The patient, a married woman, aged twenty-seven, had for three years suffered much from pain and sensation of weight and dragging in the right hypochondriac and iliac regions, increased by walking and exertion, gastric catarrh, and habitual constipation. A movable tumor was found, and clearly made out to be the kidney. As no kind of treatment or support afforded any relief, an operation was determined on. Anæsthesia was produced by bichloride of methylene, and all antiseptic precautions were followed. The patient placed on the left side, an incision, about sixteen or eighteen centimetres long, was made in the right lumbar region along the external border of the sacro-lumbar muscular mass, extending from the last intercostal space to the crest of the ilium. On cutting carefully through the parietes, the circumrenal fatty connective tissue was reached. The kidney was not *in situ*, but could be felt through the abdominal wall in the iliac fossa. An assistant pushed it up with his hand and kept it in position, while the operator, breaking through the fatty connective tissue, easily discovered the convex border and the greater part of the posterior surface. The first suture was put in the convex border: the needle traversed the fibrous capsule of the kidney. The circumrenal fatty connective tissue was raised and drawn into the wound, through the tissues of the wound directly under the lower edge of the last rib, and again through the circumrenal connective tissue. A second suture was applied on the posterior surface of the kidney, and in the deep tissues of the posterior lip of the wound. A third suture was placed in the same way in the anterior surface of the kidney, at the convex border and the deep structures of the anterior margin of the wound. With these three sutures the kidney was held in position. For greater security, the circumrenal fatty connective tissue of the lower half of the kidney was united by four sutures to the tissues of the wound. Catgut sutures were used. A large drainage-tube was applied deeply, and a small one superficially, and the wound was sewed up with seven points of deep sutures and twelve superficial. The patient bore the operation well, and her subsequent course was satisfactory. There was no fever, and the urine remained normal. The wound was dressed on the fourth day, and the drainage-tubes were removed. On the ninth day it was dressed for the second time. Cicatrization was complete; the superficial sutures were removed. On the twentieth day the patient was discharged cured. She has lost all her former pains, is perfectly well, and the kidney can be felt in its normal situation.—*London Medical Record*, May 15, 1883.

DERANGEMENT OF THE MUSCULAR SENSE IN CEREBRAL DISEASE.—In a recent lecture (*Wiener Medizin. Blätter*, March 1, 1883) Professor Nothnagel made some general remarks on the derangement of the muscular sense in cerebral disease. The muscular sense is disordered in the following circumstances: 1. When patients cannot distinguish between weights. 2. When they have no idea of the position of their limbs, and are unable to imitate with one limb a movement which has been made passively with the other. 3. When ataxic symptoms are present, *i.e.*, when the gait is staggering, or when the patient cannot use the upper extremities for such movements as putting in a button. The symptoms point to morbid processes in the cerebellum, corpora quadrigemina, pons varolii, thalamus opticus, centrum ovale, or cortical substance. In the cerebellum the affection is not of the hemispheres, but of the vermis, and Nothnagel is inclined to think only the deeper part of the vermis; but more exact knowledge on this point is wanted. Sideward inclination comes on when the crus cerebelli is injured. In the corpora quadrigemina, the seat of lesion seems to be the posterior pair; in the pons, we know that the injury must be near the centre, but the exact spot has not been discovered. Our experience as regards the optic thalamus is very slight; one case has been observed by Hughlings Jackson where weights could not be distinguished, and Flourens believes from his experiments that the position of the limbs is not known. There is not much to say of the centrum ovale, and in the cortical substance the central evolution is now supposed to be the seat of injury, instead of the parietal, as formerly; and the more superficial the injury is, the more will the muscular sense, and not the motility, be disturbed. Clinically, both extremities are affected when the lesion is in the pons varolii or cerebellum, whilst in affections of the cortical substance the muscular sense is disturbed only on one side. Staggering gait seems to occur in connection with dizziness. In cortical lesions weights cannot be distinguished, but the ataxic gait is seldom seen. In some cases of injury to the pons co-ordination only was disturbed; in others the muscular sense also.

ENCHONDROMA OF BOTH LUNGS WITH SECONDARY GROWTH IN BRAIN.—Dr. Churton, in the *Lancet*, March, 1883, gives notes of the case of a girl, aged eighteen, who came under his observation for shortness of breath and severe cough. The left leg had been amputated four years previously, but the exact nature of the disease was not ascertained. There had been wasting for sixteen months before she came under Dr. Churton. On examination, there were the usual signs of effusion on the right side of the chest, and subsequently several ounces of blood-stained fluid were removed by the aspirator. After two or three weeks of frequent headache and vomiting, twitchings of the left arm and hand were noticed; and after this patient had fits at intervals, remaining unconscious for an hour or more. The patient gradually became worse, and died about two months after her admission. The post-mortem examination showed a hard, bony growth of the lower part of the right lung, with scattered nodules through the anterior part, and also in the left lung. In the substance of the right cerebrum was a growth weighing nine drachms, which on examination proved to be ordinary osteo-enchondroma.

THE PICRIC ACID TEST FOR ALBUMEN.—Dr. Johnson, *British Medical Journal*, May 7, 1883, gives the following additional details concerning this test:

It should always be borne in mind that, in testing for albumen, the picric acid must be in excess. A few drops of a saturated solution of picric acid in a highly albuminous specimen will form a coagulum, which is quickly redissolved. When urine contains much albumen it should be mixed with its own volume of the picric acid solution; and in testing a fresh specimen, it is better to begin by adding an equal volume of the test liquid.

¹ Birmingham Medical Review, January, 1883.

One difference between picric acid and nitric acid as tests for albumen is, that whereas an excess of nitric acid, especially when the urine is heated, will entirely redissolve the previously precipitated albumen, no excess of picric acid will redissolve the precipitate which it has once found in an albuminous solution. Picric acid solution on the surface of the urine is applicable only for the detection of a minute trace of albumen. For this purpose he advises that a column of urine four inches in height should be poured into a six-inch test-tube, and upon this one inch of the picric acid solution. The result is that the upper layer of the urine is mixed with about its own volume of the test liquid; and if albumen is present, the stained portion of the urine is instantly rendered more or less opalescent, and thus contrasts with the unstained and transparent urine below. If the picric acid solution were allowed to flow so gently on to the surface of the urine as merely to come in contact and not to become mixed with its upper portion, the albumen, if present, would not be detected, or it would be indicated only after an interval of some minutes, when the two liquids had become mixed by slow diffusion. There must be an actual mixture in about equal proportions, and not merely contact of the two liquids, to ensure the action of the test.

The slight opalescence caused by the picric acid solution in a sample of urine which contains a mere trace of albumen is always increased by the application of heat. So that if the flame of a spirit-lamp be applied to the upper part of the opalescent column, this will become more opaque than the lower part, which had not been exposed to heat. He now invariably applies heat to a specimen of urine, which has been rendered opaque, or more or less coagulated, by picric acid. His chief reason for this practice is to ascertain if peptones ever appear in the urine. In a paper published in the *Journal*, March 31st, he has shown that, whereas the albuminous precipitate with picric acid is rendered more opaque and coherent by heat, the precipitate which picric acid gives with peptones is entirely redissolved by heat considerably below the boiling-point.

The microscope alone would serve to distinguish the precipitate caused by picric acid with peptones, with urates, and with albumen respectively. The precipitate recently thrown down with artificially prepared peptones appears under the microscope quite homogeneous, and free from solid particles; but when the precipitate having been dissolved by heat, reforms on cooling, it seems to consist of numerous very minute, apparently globular particles, in which the so-called "Brunonian movement" is very active. The microscopic appearances of uric acid and urates are so well known as to need no description.

The precipitate produced by picric acid with albumen presents irregular clusters of granular material, which appear much larger and more opaque after the application of heat. According to his experience, a deposit of uric acid and urates is about as rare a result of adding picric acid to urine as a similar deposit caused by nitric acid; and hitherto he has met with no specimen of urine in which the presence of peptones has been indicated. A deposit thrown down by picric acid and redissolved by heat, may pretty safely be assumed to consist of urates, but in any case of doubt the addition of Fehling's solution and the microscopic appearances will at once serve to distinguish between precipitated peptones and urates.

DYSENTERY AND LIVER ABSCESS.—In a paper on the relation of hepatic abscess to dysentery, Sir J. Fayer (*Lancet*, May 19, 1883) summarizes his opinions as follows: 1. The so-called abscesses which originate in local deaths of parenchyma (pyæmia, embolic deposits, or infarcts) are cavities varying in size from a mere speck to an orange, containing debris, sanies, puriform matter, leucocytes, and, finally, pus. They are seen in various stages of development, and are not necessarily confined to the liver, but occur in other viscera or regions of the

body. These are truly pyæmic. 2. There is a form of liver abscess co-existent with, and perhaps due to, dysentery, which is the result of direct absorption and transference of pus or septic matter from the bowel to the liver through the mesenteric veins. Such may be solitary, double, or triple. This is also a very dangerous form of the disease, though not necessarily fatal, as it is feared must always be the case in the former variety.

3. Dysentery, malarial fever, and hepatitis may co-exist, or supervene on each other as effects of common climatic cause; it seems natural to ascribe the liver abscess in such cases to the dysentery, but it is probable that they are rather coincidences than consequences of each other, and that the cause which affects the glandular structures of the large intestine may determine the mischief in the liver in certain climates and localities; such are obviously very different from those previously mentioned. 4. The ordinary large and most frequently single tropical abscess is quite independent of dysentery, though it may co-exist with or follow it. Each or all of these forms may, in England, be the result of disease originally contracted in certain climates.

THE NITROUS COMPOUNDS IN ANGINA PECTORIS.—Dr. Hay has instituted a series of experimental observations touching the value of nitric, nitrous, and nitro-compounds in angina pectoris (*The Practitioner*, May, 1883). He concludes therefrom that nitrous acid in any combination, whether as an ether or a metallic salt, is useful in the treatment of angina pectoris; and that, in the case of the nitrite of amyl, the action of the acid is aided by that of the base. On the other hand, all compounds of nitric acid, whether ethereal or metallic, are without effect, unless it so happen that the constitution of the nitrate is such that it decomposes in the body with the liberation of nitrous acid. Further, nitro-substitution compounds have likewise no remedial effect. So far as at present known, the nitrogen-containing remedies for angina pectoris may be divided into two classes, the one consisting of combinations of nitrous acid with metallic oxides or alcoholic radicals, the other comprising a peculiar class of nitric ethers, obtained from the higher alcohols, whose decomposition within the body results in the production of nitrous acid. In both classes the action of the compound is ultimately dependent on the nitrous acid present. Typical examples of the first class are nitrite of sodium and nitrite of ethyl, and, of the second class, nitro-glycerine. To these classes might be added another containing such substances as compounds of amyl, whose action is similar to that of nitrites. But, limited as this group at present is to compounds of amyl, it is not one to be chosen in the treatment of angina pectoris. The dose required is large, and the action is not rapidly produced, and disagreeable after-effects are apt to occur; and altogether I am very doubtful of its always acting so well as it did in the case of my patient.

CHANGES IN THE CARDIAC NERVES IN HEART DISEASE.—From a number of examinations of hypertrophied hearts with valvular lesions, Dr. Putjatn (*Virchow's Archiv.*) concludes that: 1. In chronic affections the nerve-ganglia are affected by an encroachment of the inflammatory process. 2. In cases of early and relatively slight disease the changes are restricted to hyperæmia and granular degeneration. In chronic and extensive affection of the heart there are evidences of interstitial inflammation with the production of fine connective tissue, while the ganglion cells themselves present appearances of fatty and pigmentary degeneration. In one case there was entire destruction of the ganglion cells, with calcification of the tissue between them. 3. Aside from local trouble in the heart and aorta, changes in the ganglia may be called forth by chronic constitutional disease. 4. The above described lesions cannot be without influence on the physiological activity of the heart. In this way many of the functional disturbances

and even paralysis of the heart, when fatty degeneration is not present, can be explained. Possibly, also, some forms of angina are referable to the same cause.

Uskow has also studied the nerves of the heart, in cases of hypertrophy combined with chronic interstitial nephritis (*Virchow's Archiv*). He has found that with the growth of muscular tissue the medullary sheath of the nerves is lost, and a process of nuclear proliferation commences. Should an acute disease supervene, then the changes in the affected nerves assume the character of an acute parenchymatous inflammation. In the nerve-cells lying in the course of the fibres, as well as those in the ganglia of the septum atriorum, the changes were confined to thickening of the capsule and increase of nuclei. The protoplasm itself was unaffected.

THE RAPIDITY OF CEREBRAL ACTS.—Dr. René has made a series of experiments on the rapidity of transmission of impulses through nerves, and the rapidity with which cerebral acts are performed. He finds (*Gaillard's Journal*) that the intensity of the stimulus has a direct influence on the rapidity of nervous transmission. The stronger the stimulus the more rapid the transmission. The rate of transmission cannot, therefore, be stated in exact terms, since it is relative, as has been not unfrequently noted for other kinds of cellular activity. He has also confirmed the fact, now very generally admitted, that it is impossible to measure the rapidity of transmission in sensory nerves by stimulating different points of their length, for the rapidity of the response is not proportionate to the length of the nerve traversed. Thus the response to a stimulus applied to the finger is often made with a shorter interval of time than a stimulus applied to the elbow or to the shoulder, though the length of nerve called into play is much greater in one case than in the other. In a word, it is impossible to compare the results obtained from different regions. The most exact method of measuring nervous transmission appears to be that of response to an auditory stimulus. The rapidity with which nervous impulses are here conducted he estimates at twenty-eight metres per second, which is a little lower than the number obtained by other physiologists. For the rapidity of transmission of motor impulses René gives twenty metres per second, which is below that of other experimenters. The duration of a cerebral act he estimates at $\frac{3}{100}$ second. In young infants the duration is more considerable, amounting to 0.090 second. The duration of a reflex act—that is to say, the time occupied by the entire reflex arc, sensation, transmission to the cord, including motor impulse and muscular movement—is 0.15 second.

CEREBRAL VACUOLATION.—At a recent meeting of the London Pathological Society (*British Medical Journal*, May 17, 1883) Dr. White read a paper, written conjointly by Dr. Savage and himself, on vacuolation of the cerebral substance. It was shown that there were nine causes for holes in the brain: 1. Small processes of sclerosed meninges, in cases of general paralysis, dipped into and excavated minute portions of cerebral tissue. 2. In the same disease the sclerosed neuroglia, by its contraction, might give rise to small cavities. 3. There might be multiple hydatids in the brain. These three conditions were very rare, the authors having no knowledge of the second, while the third was almost confined to animals suffering from staggers. Several references to continental authors were given, while the relation of the muslin appearance to the second of the above was pointed out. 4. The fourth cause was the dilatation of cerebral vessels giving rise to the "*état criblé*." It was particularly emphasized that this was, in the majority of cases, of no pathological significance. 5. Shrinking of the cerebral convolutions in some cases gave rise to holes in the subjacent cerebral substance; a very good example of this condition was exhibited. 6. Miliary aneurisms, as Charcot had pointed out, might give rise to holes in the brain-substance; some very

marked specimens showing this were exhibited. 7. In the condition known in Germany as *die Porencephalie*, a large gap existed in the brain-substance; this might communicate either with the exterior or the interior of the brain, or both. 8. The Gruyère cheese condition. This, it was pointed out, was quite different from the "*état criblé*," for it was due to a dilatation of the perivascular lymphatic space of His. Of the causes of this dilatation nothing was known; probably they were local, and the dilatation was saccular. The authors showed an example of this condition in which the whole of the brain, except the lower part of the medulla, was riddled with cavities exactly like those found in cheese, and microscopic specimens exhibited showed that these holes were produced by this perivascular dilatation. The shape and direction of the cavities also corresponded with that of the vessels. Very few examples of this condition had been carefully described; in England only one, by Lockhart Clarke, who referred it to the same cause. 9. The authors showed specimens from two remarkable cases, in which the kidneys, lungs, liver, heart, and brain all contained holes; in the kidney, these cysts were due to the dilatation of either the tubules or Malpighian capsules; in the liver they were due to the vacuolation of the hepatic cells; in the lungs and brain it was impossible to come to any definite conclusion as to their origin, but in both these viscera the cavities contained a peculiar material, staining deeply with logwood; both the subjects were lunatics. Cases in which there were found only a few holes, such as patches of softening hemorrhage, were not considered to come within the scope of the paper. Dr. Savage said that, in the cases of the two lunatics last referred to, the changes were certainly not due to changes produced by preservative fluids after death, as the vacuolation was noticed at the necropsy. Both the patients were general paralytics, but in one the disease was chronic (three or four years), in the other acute (three or four months). He was convinced that the vacuolation occurred under various conditions.

THE LOCAL ORIGIN OF MALIGNANT GROWTHS.—Mr. Jonathan Hutchinson, in the *British Medical Journal*, March, 1883, contributes a paper on the nature and scope of the local influences which induce malignant action. "The more we investigate, the more clearly will we see that all inflammations are really infective, and that inflammatory processes may pass by almost insensible gradations into those of malignancy." It is not so much senility of the entire organism as local senility (an old age of the tissues concerned, which is premature, and does not correspond with that of the body as a whole) that is almost always necessary to the production of cancer, exceptions occurring, however, in cases due to the influence of inheritance. Tissues and organs which are just passing out of use are those most prone to develop cancer. As to the inheritance of cancer, it has been urged that a disease which is capable of inheritance must be a constitutional one. This is true to some extent; but Mr. Hutchinson says that a peculiarity of cell-structure generally is inherited, not germs, not a blood-malady, but a special type of cell-organization, permitting with greater ease than in other persons the injurious influences of local causes. The rodent ulcer of the face is looked upon by the author as a form of morbid action which stands half way between common inflammation and cancer. There is also a distinct proneness possessed by parts formerly affected by syphilitic inflammation to become affected by some malignant growth. In conclusion, Mr. Hutchinson urges the adoption of his doctrine of a pre-cancerous stage, where surgical interference is necessary and ought to be insisted on, before the growth takes on any definite form except that resembling ordinary inflammation, and before the neighboring lymphatics are affected. Without this, he sees no hope of any improvement in the reduction of the mortality of cancer.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 7, 1883.

THE INSANITY OF EPILEPSY.

IN the study of epileptic insanity we find much to justify the view of the pathogeny of the falling sickness propounded by Hughlings Jackson, namely, that the epilepsies are dependent on excessive paroxysmal discharge of some part of the cerebral cortex.¹ Not to dwell on the fact that the initial symptom of the "grand mal" may properly be designated as a paroxysmal affection of consciousness, and that light seizures of the "petit mal" are constituted by abrupt temporary suspension of the conscious mental life; that epileptic attacks often begin with some strong mental emotion as fear, or anger, exhibitions of irascibility or peevishness of hours' or days' duration, forcing upon us the irresistible inference that, if the fit begins in the intellectual sphere, and consequently in the gray matter of the hemispheres, the succeeding physical processes must begin in the supreme cortical motor centres, between which and the psychical centres there is both contiguity and histological solidarity. The truth has often been pointed out that the sensory, intellectual, and motor phenomena of epilepsy are interchangeable, and that an attack of mania may take the place of the ordinary convulsive paroxysm, the derangements displaying themselves in convulsions, not of the muscles but of mind, to use Maudsley's expression.

"The physical process, in a fit beginning by loss of consciousness, is a discharge beginning in some of the nervous arrangements in the highest centres of the brain" (Hughlings Jackson). This view, which is generally accepted by those who believe in the modern doctrine of localizations, explains all the phenomena of the fit and their order of occurrence much better than the older theory, which finds the point of departure of the paroxysm in excitation of the medulla oblongata.

A remarkable example of the *furor epilepticus* taking the place of the customary convulsive seizure, constituting what is known as *masked epilepsy*, is given by Jules Falret in the *Archives Gén. de Médecine*. "François L—, shoemaker, was for many years subject to epileptic fits. The attacks, which at first were followed by but slight alteration of the reason, became more serious and were accompanied by furious mania. Sometimes the fit was replaced by homicidal delirium, as in the following instance: When he was through with his military service (he had been a soldier) he returned home and decided to marry.

The ceremony was fixed for October 26, 1841. The 24th an intense headache came on and seemed to him to betoken an impending attack. He called a physician who had formerly treated him for the disease, and demanded to be bled, an operation which had always given him relief. The physician refused to gratify his request. The 26th, some hours before the wedding, he was bled by another physician, but without any diminution of the pain. During the marriage ceremony François was dejected and taciturn; he said nothing but the one word *yes*. On quitting the church he was seized with a most atrocious pain in the head, and when he arrived at the house of his father-in-law he was obliged to take his bed. The bed-chamber was adjoining the dining-room where the wedding feast was being prepared. Then he was seized with an attack of epileptic madness, and while the persons who were with him were hunting for cords to tie him, he precipitated himself naked into the dining-room, with a shovel, of which he had obtained possession, pursued a woman who fled before him, threw her down and inflicted heavy blows on her head. His father-in-law interposed, when he flew at him and drove him from the house. He cast himself on the ground before the door, biting the threshold with his teeth; then he rose with a shoe-knife in his hand, opened the door with force, crying out that he would kill them. The first person he met was his father-in-law, whom he instantly killed. This attack lasted three days. On the 28th instant his reason returned, but he remembered only the event of his marriage, and nothing of that which came after. He supposed that he had slept all that time. He was at once removed to the asylum of Clermont, where he still remains.

Lesegue relates similar instances where the fits were preceded or replaced by the "delirium of impulse." In one remarkable case, that of the assassin Thouviot, light was shed on the extraordinary motiveless murder of a young girl, by the subsequent occurrence, while the homicide was in jail, of two epileptic fits.¹

The epileptic paroxysm is often preceded by grave intellectual troubles. Bellod relates an observation in which the convulsive crisis was always ushered in by a state of melancholia, and succeeded by a state of mania. A remarkable case is recorded by Ball² of an ecclesiastic who had been epileptic for twenty years. Every month occurred a period marked by two or three complete convulsive attacks. Each of these periods was preceded, for eight or ten days, by a melancholic delirium, characterized by ideas of persecution and by hallucinations of hearing, in which he would hear the most shocking blasphemies. After the convulsive paroxysms, and several days of hebetude which followed, he entered on a phase of *bien-être* and satisfaction inexpressible, in which he spoke incessantly of his restoration; his hallucinations of hearing had left him, and he was enabled to devote himself to his usual religious exercises. This period of *bien-être* would last a fortnight, to be succeeded by a state of melancholia and another convulsion.

In the event of a crime being committed by an epileptic, the criminal should always have the benefit of the doubt as to whether he were sane at the time. The deed

¹ Lectures on Epilepsy, by Jackson, in London Lancet, 1879. Maudsley on Responsibility in Mental Diseases, page 41 et seq.]

¹ Maudsley in his works gives many similar instances.

² Leçons sur les Maladies Mentales. Article, "Folie Epileptique."

of violence may, as Ball remarks, be but the first symptom of developing lunacy, or the result of that impulsive, brutal, badly equilibrated character which in an epileptic unquestionably diminishes the moral freedom.¹

It is true that some epileptics have been characterized by extraordinary mental activity and brilliancy of genius, and Mahomet, Swedenborg, Napoleon, have been cited as examples of epileptics, whose malady did not impair, possibly may have increased their intellectual power. It is, moreover, very probable that much which has passed current among mankind as *revelation* and as *divine*, like Mahomet's visions, was the fruit of genius under the direction of the *furor epilepticus*. Maudsley sarcastically intimates that the invention of the modern sensational novel, with its murders, bigamies, and other crimes, was an achievement of the epileptic imagination. If epilepsy be the result of morbid excitation of the supreme cortical cells, it is easy enough to trace a kinship, and often a causal connection, between this disease and any perversion whatever of imagination and genius.

That the general tendency of the epileptic neurosis is toward mental degradation, amnesia, and dementia, is proved by multitudes of facts in the experience of alienists everywhere.

It is an interesting circumstance in connection with this study, that epilepsy in the parent may engender the insane neurosis in the child, and insanity in the parent may be transmitted as epilepsy to the child. The fact that insanity is essentially a disease of the ganglia of the hemispheres, gives great probability to the theory that epilepsy, which bears such an intimate correlation to it, is itself due to abnormal modifications ("discharging lesions") of the supreme cortical cells. Moreover, the epileptic aura is a sensory disturbance, evidently emanating from some perceptive centre in close relation to the motor area of a member, and epileptic vertigo—attacks of which often precede for months the convulsive motor manifestations of the disease—is a phenomenon affecting the domain of consciousness. It is easier to understand these phenomena on the supposition that they are primarily cerebral than that they are primarily spinal.

In conclusion it should be stated that, in not a few instances, autopsies of epileptics have revealed grave, sometimes gross, lesions of the cerebral hemispheres.²

THE END OF THE STATE MEDICAL SOCIETIES.

SINCE February last we have furnished to our readers records of the meetings of twenty-six State Medical Societies, of three national organizations of specialists, and of the American Medical Association. This certainly shows that there is much activity among American physicians. Whether this activity has correspondingly enriched the science of medicine we will not undertake to say. It is to be borne in mind that although each of the States in the Union has its own Medical Society, many of these organizations have hardly more than a nominal existence, so far as real medical work is concerned. We have received several complaints to the effect that the reports

of these societies are not interesting nor instructive reading. The charge is in a measure true, yet it will be found that few State Societies meet without doing something worthy of note. We trust that we shall not be accused of sectarian jealousy if we intimate that decidedly the best work has been done in the New England and Middle States.

Having watched for some twenty years the growth of State Societies, we are glad to be able to say that in the last few years they have been steadily improving. The meetings are better attended, more papers are read, and more interest is shown. It must be admitted also that more dinners are eaten and more excursions are made.

State Medical Societies are very useful agents in the promotion of mutual acquaintance and good feeling, as well as in maintaining that *esprit de corps* which is so valuable to the profession. A cordial shake of the hand, a dinner at the same table, will do more than any by-laws to secure the proper relations between physicians. We urge upon physicians, therefore, an increased interest in their State Societies. The majority of them have still their potency for good in a very crude and undeveloped condition.

A HOUSE DIVIDED.

IT seems that all the defenders of the American Code of Medical Ethics are not satisfied with the election of Dr. Austin Flint to the Presidency of the American Medical Association. The objection (which is made by a correspondent of the *New York Medical Journal*) is not that Dr. Flint did not deserve it on personal grounds, but that he does not stand by the old Code in its entirety. The writer referred to says:

"It is scarcely more than a month since Dr. Flint, through the columns of your own journal, labored to break down the force of the restrictive clause in the Code, and concluded by saying: It is to be hoped that the American Medical Association will adopt such modifications in the phraseology of this section as will place restrictions in consultation, not on the ground of doctrines or forms of belief, but on separation from and avowed antagonism to the medical profession. Now, when it is remembered that, on the ground of doctrines and forms of belief, we thrust the homeopaths neck and heels out of the profession, and ourselves created the 'separation' and 'antagonism,' I submit that Dr. Flint does not leave us a visible leg to stand upon. Heaven save us from our friends!

"But I am glad to see that Dr. Flint has so far reconsidered his views as to be able to sign the required pledge to sustain the Code as it is. I hope there is in this case none of that mental reservation referred to by Dr. Flint, Jr., at the Academy, and so ably exposed by Dr. Squibb in the article to which I called attention last week, and that we shall not be mortified next year by any movement toward a change. I am the more solicitous about this as I am informed that a great many joined the movement for re-enacting the old Code in this State in the belief that our leaders would initiate some action in the association this year looking to revision."

There exists much confusion in the minds of many as to the real significance of the "restrictive clause" in the old Code. Some think that it is right as it is, others,

¹ "It were as unreasonable to hang a man for not stopping by an act of will a convulsion of which he was conscious."—Maudsley: *Body and Mind*, p. 66.

² Vide recent papers by Seguin and Jackson.

like Dr. Flint, think that it ought to be changed; and still others think that as it stands, the clause does not really forbid consultations with educated and liberal homœopaths. There has been a great deal of mutual congratulation over the fact that no discussion or dissension regarding the Code took place at Cleveland. But after all would it not have been better and manlier to have faced the matter courageously, and shown some consideration toward the strong feeling, shared, if not initiated by Dr. Flint, that some change is needed.

So far as the position of the profession before the world is concerned, we can only repeat that every week brings new expressions of condemnation and contempt for the unwise and timorous policy of the Association.

LOCATING YOUNG PHYSICIANS.

THE General Association of French Physicians, which met in Paris not long ago, has undertaken a project which is certainly unique and which promises to be very useful. It proposes to organize a bureau for the purpose of securing information regarding the most desirable places in which recently graduated physicians may locate. At present, we are told, many young men leave college with no definite idea as to where they had best go. In consequence they often choose a location without fully understanding what the prospects will be for them, and have to wait a long time before a respectable practice is secured, or perhaps have to abandon the field finally and go elsewhere.

It is proposed to obtain, by correspondence and otherwise, a kind of topographical chart showing where physicians are most needed and where the best prospects for new comers are to be found. The association will also act as agents for those physicians who wish to retire or sell out, or leave their practice for a time.

The plan is highly commended by the French medical journals, and we presume that it can be made to work successfully in France. In this country the difficulty would be in finding any place where a new doctor is wanted. With the young American graduate the question generally is, not where is there an opening, but where is the field least occupied. The advice very frequently given, therefore, is to go to the place which one likes best, and there stick till practice comes. Old Dr. Crosby, of Hanover, used to say for the comfort of his young pupils: "Whereas once I was young, and now I am old; yet have I never seen the intelligent physician forsaken or his seed begging bread."

THE APPEARANCE OF ASIATIC CHOLERA.

Two months ago some cases of Asiatic cholera appeared in Bombay. But little attention was paid to them, and the English Government, whose general policy is not unfavorable to quarantine, is charged with neglecting to take proper precautions against the disease which thus developed. About a fortnight ago a few cases appeared in Damietta, a town of about thirty thousand inhabitants, lying on the east branch of the Nile, between Port Said and Alexandria. In a few days the disease had spread with an appalling rapidity, and in the seven days ending July 4th, over seven hundred deaths were reported.

Cases have also appeared in Port Said, at Rosetta, and as we write, a telegram reports a first case at Alexandria.

This rapid development of cholera in a very malignant form, has materially excited some alarm. The disease having developed on the direct route of Indo-European travel, the likelihood of its transportation is, of course, considerable. At the same time, there is less to fear than was the case seventeen years ago, when cholera last invaded European and American ports. Since that time sanitary organization has become perfected, and the profession has learnt that by quarantine, isolation, disinfection, and cleanliness, the disease can be either kept away or greatly limited in its activity.

News of the Week.

THE RHODE ISLAND MEDICAL SOCIETY held its seventy-second annual meeting at Providence, on June 21, 1883. Dr. Job Kenyon, President, in the Chair. About one hundred members were present. The Trustees of the Fisk Fund stated that no prize had been awarded for 1883. Essays were invited on the following subjects for the year 1884: 1. "The Origin and Progress of the Malarial Fever now prevalent in New England." 2. "Original Investigations in Household Hygiene." For the best dissertation on either of these subjects worthy of a premium, they offer a prize of \$300 on the usual conditions. The Library Committee reported that four hundred and nine volumes had been added during the past year. The following officers were elected for the ensuing year: *President*—Dr. Job Kenyon; *Vice-Presidents*—Drs. O. C. Wiggin and H. G. Miller; *Secretary*—Dr. Geo. D. Hersey; *Treasurer*—Dr. Chas. H. Leonard. A Board of Censors was also elected, and a Publishing Committee. The president presented a communication from the Newport Medical Society, accompanied by the draft of a law pertaining to the abolition of the coroner system in this State, and the substitution therefor of a system of medical examiners, similar to the system which has worked so well during the past six or seven years in Massachusetts. This draft of an act was presented to the General Assembly at the May Session, referred to the Judiciary Committee, and lies over until the next meeting of the Legislature. The profession in Newport, who initiated the movement, ask the State Society to co-operate in securing the enactment of this much-needed law. The Society adjourned to meet in three months at Newport.

THE NEW YORK POLYCLINIC has organized a medical society of its own, composed of members of the faculty and graduates of the institution.

THE PRICE OF HIS BLOOD.—Edward Banks, a colored man, has begun suit in the Sixth District Court, before Justice Kelly, against Dr. Henry J. Garrigues and Charles J. V. Okerberg, for \$250, as the value of eight ounces of blood taken from Banks and injected into the veins of Mr. Okerberg. It appears that on February 7th last this gentleman went to bed in a small, close room, blowing out the gas. In the morning he was found insensible. Dr. Garrigues and Dr. Frederick E. Valentine treated him, and at the suggestion of the former the operation

of transfusion was performed. The patient recovered, and now Banks, who furnished the material for the operation, claims what he considers a fair compensation.

MEDICAL DEPARTMENT OF YALE COLLEGE.—At the meeting of the President and Fellows of Yale College, held June 27th, Dr. Thomas H. Russell, of New Haven, was appointed a professor in the Medical Department of Yale College. He will occupy, by vote of his colleagues, the chair of *Materia Medica* and Therapeutics, which is made vacant by the transfer of Professor C. A. Lindsley to the Chair of Theory and Practice. The latter chair was made vacant by the death of Professor Wilcox.

BUST OF DR. BIGELOW.—The sculptor, Launt Thompson, is at work upon a bust of Dr. Bigelow, which is to be placed in the new building of the Harvard Medical School.

PANIC IN THE AIR.—We recently suggested that there was just now an "epidemic constitution," favorable to the development of panics. This was illustrated last week by a panic which occurred upon a Fulton Ferry boat, and which was caused simply by a sudden shower of rain. Fortunately no harm was done.

CONTAGIOUS PLEURO-PNEUMONIA ON STATEN ISLAND.—The ravages of pleuro-pneumonia among the cattle on Staten Island have been increasing, and the Boards of Health in Middletown, Westfield, Castleton, Smithfield, and Northfield, are busy with the subject. In two cases the carcasses of the diseased animals, which had been hastily sold to the butcher by the owners as soon as the sickness was noticed, without inquiring into the cause, were found in the meat markets about to be offered for sale. Upward of forty head have died already in one town. Stringent efforts will be made to quarantine the animals.

HATS AND SUNSTROKE.—Scientific hatters, says a contemporary, are beginning to discover that the liability to sunstroke when the head is covered with a low-crowned straw hat is as 100 to 1 compared with a high-top beaver. The true summer hat has not yet been invented. When it does appear it will be a cone-shaped affair, light, and lined with sponge, and surrounded by a broad brim.

We very much doubt the important relation above described, between hats and sunstroke. High temperature, exposure, over-exertion, indiscretions in food and drink, bring on sunstroke without much reference to high or low crowns, or the popular cabbage-leaf.

SMALL-POX AMONG THE INDIANS.—A despatch from Dr. Warren Day, of the Mohave Indian Agency, Arizona, states that there is a general outbreak of small-pox among the Arizona Indians. Supplies of fresh vaccine virus are urgently requested.

THE FIRST VESSELS OF THE SEASON WITH YELLOW FEVER on board arrived at Ship Island June 28th and 29th. They were at once quarantined and disinfected.

THE STATE BOARD OF HEALTH held a special meeting at the Capitol on June 29th. The sanitary committee submitted detailed statements of its work under the laws to prevent the adulteration of food and drugs and to prevent the sale and use of dangerous illuminating

fluids, especial reference being made to an injunction placed upon the sale of what is called "lie tea."

Mr. Erastus Brooks presented the subject of the alarming increase of pleuro-pneumonia in milch cows on Staten Island, and asked what aid the Board could give in helping to suppress the plague and to punish those responsible for it. The Board passed a resolution calling the attention of the National Commission on Cattle Plagues to the cases. The Board will meet at Ogdensburg on August 9th.

RESTRAINED FROM ISSUING DIPLOMAS.—The College of Physicians and Surgeons, of Buffalo, known also as the Mohawk College and the College of Rational Medicine, which tried to get a charter from the Legislature last winter and failed, its true character being shown up, has recently become involved in a legal complication. It has prepared about twenty young men for graduation, but at last an injunction was secured from Judge Haight forbidding the college to issue certificates or diplomas as a legally incorporated college of medicine and surgery. The college claims legal incorporation under the laws of 1882, and the question whether this claim is well-founded will be argued in court, probably in September. Until that time no further action will be taken.

It will be remembered that this college stands on about the same footing as the U. S. Medical College of this city.

UNFORTUNATE COUNTER-PRESCRIBING.—A Second Avenue druggist in this city who attempted counter-prescribing has, along with his patient, come to grief. It appears that he advised a woman who inquired of him for a physician to take his own counsel for her sick husband, and prescribed for the patient, whom he had not seen, a medicine which the patient took and shortly after died, in spite of the efforts of some physicians, who declared that he died of poisoning by opium. Everybody will wish, if this story turns out to be true, that Leman may receive the extreme penalty of the law for his quackery.

THE TAX UPON PATENT MEDICINE ceased on July 1st. Most of what did go into the hands of the Government, will now enrich the owners of patent cure-alls. We trust that they will be able to pay their religious weekly supporters with increased liberality.

THE NUMBER OF PHYSICIANS IN NEW YORK CITY.—Some special inquiries having been made of us regarding this, we would say that the total number of physicians and surgeons in New York State in 1880, according to the United States Census, was 9,272. This number has now undoubtedly swollen to 10,000.

In what, for distinction's sake, may be called the Physician's Medical Register for 1883-84, a list of only 2,684 names is given, which number represents the regularly educated physicians in affiliation with regular medical societies. The remainder are composed of homeopaths, of whom there are probably 500 or 600 in the State, eclectics, and nondescripts.

SYPHILIS IN THE NINTH CENTURY.—The Chinese are first in everything; the Japanese press them hard, and in the matter of syphilis, seem to have precedence. Between the years A.D. 806 and 810, says the *British*

Medical Journal, an emperor of Japan commanded his court physicians, Abemans and Idzumo Kirotsada, to collect in one volume all extant records of native medicine and surgery. A manuscript copy of this work, for centuries forgotten, although the facts of its origin were recorded in Japanese history, was found in 1827 by a priest, in a provincial Buddhist temple. Dr. Scheube, of Leipzig, has recently examined this work, and, in an article published in a recent number of *Virchow's Archiv*, has shown its undoubted authenticity and its high value from a purely scientific point of view. It was written long before Chinese ideas had penetrated into Japan and influenced native practitioners. The most interesting passages are descriptions of local and general affections, which clearly prove that syphilis, and several allied disorders, were well known to the ancient Japanese. Chancroid and phagedenic chancre are clearly described, as well as a "swelling on the penis, of the size of a millet-seed," followed by eruptions, feverishness, pains in the bones and head, blindness, swelling of the testicles, and other very familiar symptoms. These were observed to continue for many years. The passages of this work, called the "Daidorui Thiu-ho," which relate to the treatment of these symptoms, have not yet been translated into English. Herbs alone appear to have been used, and without much success; mercurial treatment was introduced at a comparatively recent date, from Europe. The ancient Japanese surgeons do not appear to have recognized the venereal origin of the disease which they describe, although the "Daidorui" distinctly traces all the secondary symptoms to "the poison from the affected organ."

DAMAGES FOR THE DESTRUCTION OF EXAMINATION PAPERS.—A recent decision in a Cincinnati Justice Court will perhaps alarm some of our medical teachers who think too lightly of the intellectual efforts of medical students. A young lady medical student, the plaintiff, was a graduate of Pulte Medical College for the year 1883. The examinations at the close of the term were conducted in writing, and under test conditions. Dr. Hartshorn, the Professor of Surgery, conducted the examination on that subject by writing a list of twenty-three questions on the black-board, and requiring the students, in his presence, to write the answers. The plaintiff wrote about seventeen pages of manuscript in answering the questions, and handed the same to her Professor. Afterward, having determined to have the several results of her examinations published in pamphlet form, as an aid to her in starting in her profession, she called upon the members of the College Faculty and requested a return of the papers, or copies thereof. All of the professors so requested returned the papers, except Dr. Hartshorn, who, instead of giving her the papers, or a copy, threw them in the fire and burnt them up. The strange conduct of the Professor could not be explained satisfactorily, and upon the facts and testimony relative to the value of the papers, the court assessed the damages for the destruction of the same at \$300.

A RARE CASE INDEED.—The *Australasian Medical Gazette* publishes the following account taken from a New Zealand paper of February 23d: "A most extraordinary and painful phenomenon has lately occurred in Warsaw. A lady died under somewhat peculiar circum-

stances, which gave rise to a report that her death had been caused by her husband's ill-treatment. Hence, several weeks after the interment, her body was exhumed for post-mortem examination, when it was found that in the grave a perfectly healthy child had been born. This gives a startling new meaning to the word 'posthumous.'"

Upon the above the editor of the *Gazette* comments as follows: "This case, though extraordinary, is possibly true, two similar cases being recorded, one in the *Medical Gazette*, vol. xlv., p. 713, the other in *Casper's Vierteljahrsschrift*, 1861, p. 186. It is more probable, however, that the woman was buried in a state of suspended animation, and that the birth took place during her life. If it took place after life had departed, it is certain it occurred almost immediately after death, and before the muscular contractility of the uterus had ceased, the body having been confined very quickly, and the child remaining unnoticed prior to burial."

LISTER ON LISTERISM.—Professor Lister has written the following letter to Mr. Henry Gray Croly, in response to an inquiry whether he had given up the spray in operations:

DEAR MR. CROLY: I have not given up the use of the spray, although I certainly regard it as the least important part of our antiseptic arrangements. Whatever other good it may do, it is a very mild form of antiseptic irrigation, and tends to keep the *entourage* of the wound, including the surgeon's hands and instruments, pure. But if I had not a spray-producer at hand, I should not on that account omit other elements of antiseptic treatment. I still use the spray in changing dressings, so long as the wound is not merely superficial. But far more important than using the spray is it to make a point of covering the wound with some pure antiseptic material before beginning to wash the parts which were covered with the edge of the dressing only, and were therefore impure. In other words, I believe one of the commonest causes of failure is dabbing alternately the impure surrounding parts and the pure wound with the same piece of rag, which, though moistened with carbolic lotion, cannot work miracles.

Believe me, yours very truly,

JOSEPH LISTER.

Obituary.

BEVERLY LIVINGSTON, M.D.,

NEW YORK.

It is most sad to have to record the death of one who, after years of hard work and careful preparation, had just begun to enter a brilliant professional career. Dr. Beverly Livingston, who died most suddenly and unexpectedly of diphtheria, on June 30th, was born in 1852. He graduated at the Sheffield Scientific School, at Yale, and took his medical degree at the College of Physicians and Surgeons of this city in 1877. He entered Bellevue Hospital as an *interne*, and was there for two years. He then went to Europe, and studied several years in Paris and in Germany. Returning to this city, he began his practice here under the most promising circumstances. He was attending physician to the Nursery and Child's Hospital, member of the Academy of Medicine and of the Pathological Society. He had already shown unusual attainments as a pathologist, as well as practical skill as a physician. Personally Dr. Livingston was a general favorite, and few young men had a wider circle of friends. In his death the profession has sustained a loss which all who knew him will keenly appreciate. For ourselves with our sorrow we can but feel a bitterness at the fate which so ruthlessly cut down in an hour the labor and promise of years.

Reports of Societies.

MAINE MEDICAL ASSOCIATION.

*Thirty-first Annual Meeting, held in Portland, Me.,
June 12, 13, and 14, 1883.*

GEORGE E. BRICKETT, M.D., OF AUGUSTA, PRESIDENT,
IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

FIRST DAY—JUNE 12TH.

A BIOGRAPHICAL sketch of Dr. Alexander Ramsay—who was a very prominent medical teacher in this State seventy years ago—written by Dr. Geo. P. Bradley, U. S. N., was presented, and referred to the Publication Committee.

DR. S. P. WARREN, of Portland, reported a case of absence of uterus in a married woman, and a case of cyst in the vesico-vaginal wall.

A committee was appointed to consider the question of providing a banquet, and, on its recommendation, a committee, with Dr. J. M. Bates, of Yarmouth, as chairman, was chosen to report on the subject next year.

THE PRESIDENT, in his inaugural address, paid a fitting tribute to his predecessors, sixteen of whom are still alive. He recommended efforts to secure

THE ESTABLISHMENT OF A STATE BOARD OF HEALTH, AND
A BOARD OF REGISTRATION.

Stress was laid upon the value of investigations into the properties of new remedies. The medical schools at Portland and Brunswick, and the Maine General Hospital were commended, and loyalty to the Code of Ethics of the American Association enjoined.

Certain proposed amendments to the constitution, introduced by Dr. E. F. Sanger, of Bangor, were acted upon. Those relating to discipline, and which, if adopted, would bring into the meetings differences between members which are now disposed of by the censors, were rejected by a unanimous vote; and a similar fate attended those which related to officers and membership. As their author was not present, there was no voice to support them.

DR. O. ST. C. O'BRIEN, of Bristol, visitor to the Portland School for Medical Instruction, reported that the institution was in excellent condition, and that it presented unusual facilities for obtaining an education.

DR. J. G. PIERCE, of Freeport, read a paper on

SYNOVITIS,

emphasizing the advantages of treatment with the aspirator and elastic bandages.

DR. A. K. P. MESERVE, of Portland, presented an essay

ON ACUTE INFLAMMATION OF THE MIDDLE EAR.

A very large proportion of these cases comes to the general practitioner for treatment, and it is, therefore, important that the profession generally should be familiar with their management. The paper was eminently practical.

DR. H. N. SMALL, of Portland, read an elaborate paper on

EXTRA-UTERINE FETATION,

illustrating the subject by a description of a fatal case in his practice. In the discussion which followed, a number of members reported cases which they had seen. One was mentioned in which the fetus became calcified, and remained in the abdomen many years—the woman, meantime, bearing a number of children.

DR. S. H. WEEKS, of Portland, made some extended remarks on fractures of the elbow-joint. An animated discussion ensued, some members advocating the rectangular position of the joint in the treatment of most cases, while others favored the straight position, in ac-

cordance with the theory of Dr. Allis. A marked difference of opinion obtained also with reference to the time of beginning passive motion.

SECOND DAY—JUNE 13TH.

DR. O. A. HORR, of Lewiston, visitor to the Medical School of Maine, reported that the institution maintains its high standard in all respects. The examinations are strict and searching, and a diploma is granted to no one who does not reach seven on a scale of ten. The new anatomy law has operated to the advantage of the school.

DR. E. E. HOLT, of Portland, read a paper on diseases of the mastoid.

The Committee on Revision of the By-Laws, appointed last year, was discharged from further service, and its work was assigned to the Publication Committee.

DR. A. H. BUREBANK, of Yarmouth, read a paper on

THE INDUCTION OF PREMATURE LABOR,

in cases where contraction of the pelvis forbids the birth of a living child at term. He believed this procedure should be instituted much more frequently than it is, and recommended gradual dilatation of the os with the digit.

DR. J. T. DANA, of Portland, introduced

THE SUBJECT OF BRIGHT'S DISEASE,

detailing the symptoms of various forms, and illustrating his points with accounts of several typical cases. We are justified in a more hopeful prognosis in many cases than formerly, when the pathology of the disease was less perfectly understood.

DR. J. A. SPALDING, of Portland, read a paper giving an account of the testimony in a trial for alleged malpractice, where he was called as an expert.

The necessity of the early removal of an eye which is the subject of traumatic inflammation was carefully discussed and illustrated.

The officers for the ensuing year were then elected.

The annual oration was pronounced by DR. M. C. WEDGWOOD, of Lewiston, whose subject was

RATIONAL MEDICINE AND QUACKERY.

He spoke of various forms of charlatanry which have adopted particular names, but dwelt particularly upon quackery as it is often met with in the regular profession, displayed by men who prate about their allegiance to codes, and yet undermine and traduce their fellows. Rational medicine will achieve its greatest triumphs only when education of mind and heart and hand are insisted upon in all its disciples. All exclusive dogmas—allopathy as well as homeopathy—are based upon error, while rational medicine embraces every truth from whatever source.

DR. B. F. STURGIS, of Auburn, reported a case of chronic abscess of the tibia.

DR. S. C. GORDON, of Portland, the Committee on Necrology, presented biographical sketches of the following deceased members: A. Crosby, Waterville; W. H. Brown, Bangor; R. Curtis, Richmond; J. P. Grant, Saco; W. W. Greene, Portland; W. Sweat, Hollis; R. E. Paine, Camden; D. M. Telford, Portland; and D. F. Ellis, Brunswick.

DR. F. H. GERRISH, of Portland, reported

A CASE IN WHICH THE BLADDER WAS DIVIDED BY A SEPTUM,

so that a lithotrite could not be so introduced as to reach a free calculus, which was easily touched with a catheter. Lateral lithotomy was performed, and the patient, though seventy-five years old, did not have an unfavorable symptom afterward.

DR. GORDON read a paper on the treatment of some accidents occurring during parturition, devoting especial attention to lacerations of the cervix, ruptures of the perineum, and cystocele. The essay displayed great familiarity with the subject, and abounded in illustrations drawn from practice.

THIRD DAY—JUNE 14TH.

The Board of Censors made their report in substance as follows :

It was recommended that the next annual meeting be held in Portland, on the second Tuesday in June, 1884.

Orator—Dr. A. L. Hersey, Oxford. *Delegates to other medical societies*: New Hampshire—Drs. T. A. Foster, Portland, and D. L. Lamson, Fryeburg; Vermont—Drs. W. C. Mason, and R. K. Jones, Bangor; Massachusetts—E. H. Hill, Lewiston, and A. M. Peables, Auburn; Rhode Island—C. T. Moulton, Cumberland, and J. L. Horr, Cumberland Mills; Connecticut—O. St. C. O'Brien, Bristol, and A. J. Billings, Freedom.

Visitors to Portland School for Medical Instruction—C. A. Packard, Bath, and J. A. Richards, Farmington. *Visitor to Medical School of Maine*—S. Laughton, Bangor.

It was recommended that Dr. W. H. Simmons' request, to be allowed to withdraw from the Association, be granted. It was reported that Dr. C. Seavey, of Bangor, had been tried on charges preferred by Drs. Sanger and Mayo, and that the charges were not proven.

A large number of applicants for membership were recommended, and were at once admitted by vote of the Association.

DR. WEEKS reported a case of immense sarcoma of the head, which illustrated the importance of early removal of morbid growths. He mentioned some of the principal features of a case of oöphorectomy which he had recently treated, and promised a full report of results at the next meeting.

The following committees to secure legislation were appointed in accordance with the recommendations of the President in his address: On State Board of Health—Drs. Dana of Portland; Bates, of Yarmouth, and Weeks, of Portland. On registration of practitioners—Drs. O. A. Horr, of Lewistown; Webster, of Augusta; O'Brien, of Bristol; Walker, of Thomastown, and Smith of Whitefield.

The customary votes of thanks were passed to the city for the use of the rooms, and to various officers; and the Association adjourned at noon on Thursday, after a very pleasant, harmonious, and profitable meeting.

NEW HAMPSHIRE MEDICAL SOCIETY.

Ninety-third Annual Meeting, held in Concord, June 19 and 20, 1883.

(Special Report to THE MEDICAL RECORD.)

THE Society was called to order at 11 o'clock A.M. The President, DR. A. H. CROSBY, of Concord, in the Chair.

Prayer was offered by the REV. F. D. AYER, and the usual committees were appointed for the session by the Chair.

Delegates being present from Vermont, Rhode Island, and Massachusetts, they were introduced to the Society and made welcome guests of the association.

After some routine business had been transacted the proceedings of the Council were read by the Secretary, from which it appeared they had recommended twenty-five physicians for new members; that only four deaths had occurred during the past year; one new district society had been chartered; matters of ethics had been duly disposed of, and all matters of new business had been attended to with due regard to the interests of the Society.

It appeared that they had taken into consideration the condition of the collections in the Surgeon-General's office at Washington, D. C., and offered pertinent resolutions looking toward the perpetuation of these valuable collections, in urging upon their Congressmen the necessity of the Government making an appropriation sufficient to construct a suitable building, with all the appointments necessary to preserve and protect these contributions to medical science from a hard-worked and self-sacrificing profession.

The proceedings of the Council were duly accepted. At twelve o'clock THE PRESIDENT read his annual address, taking for a subject

THE COUNTRY DOCTOR.

He alluded to the toil and hardships to which their professional life led in fitting terms, and comparing their resources in medicine and surgery with those of their more favored brethren, who, living near or in the great centres of population, where every known drug or surgical appliance could be found, and professional assistance could be had at a moment's notice, he said that their judicious selection of a few standard drugs, and the mechanical ingenuity they displayed in improvising surgical appliances to meet the wants of an individual case was a surprise to many a city surgeon, while the results obtained would fairly rival that attained in the large hospitals.

His address was listened to with attention, and was referred to a committee for publication.

Orations by Dr. G. C. Blaisdell, of Contoocook, and Dr. George W. Hatch, of Wilton, treated upon professional labor in general terms, while

AN ESSAY ON COLDS,

by DR. W. T. SMITH, of Hanover, was an interesting paper upon a familiar subject, but entitled to consideration, as being one to which our attention is so often called.

The speaker gave a *résumé* of the effects of cold upon the surface of the body, the shock to the system, and how its injurious influence was transmitted to the nerve-centres, and reacted upon organs and tissues at a distance from the part exposed.

He alluded to the epidemics of influenza that have passed into history, and while freely admitting that the unsanitary surroundings of the people must have had its influence in preparing the system for the easy introduction of disease, yet the atmospheric influence upon the skin and air-passages, must have been the exciting cause of their development.

DR. PRAY, of Dover, presented a long paper upon variola, of which no brief abstract would do justice, and DR. J. A. WATSON, of Concord, gave a paper

ON WATER POLLUTION.

He gave some interesting facts that had been developed in the State by the Board of Health, and the statistics of several wells that had been examined and condemned. He also appealed to all present to investigate into the condition of the water supply in all cases of a doubtful character or what appeared to be of mysterious origin, assuring the members that the Board would be glad to respond to the assistance of any one who had cases of this character to investigate.

Several other papers were read, and discussions followed until late in the evening, the anniversary dinner having been served at 2 P.M., at the Eagle Hotel.

The Society met at 8 A.M. Wednesday morning, and was called to order by the President, when the Secretaries of the District Societies made their annual reports, from which it appeared that they were in a flourishing condition.

The Treasurer made his report, showing the Society to be in sound financial condition, having about sixteen hundred dollars in the bank and current funds.

The election of officers followed, and Dr. John W. Parsons, of Portsmouth, was elected President; Dr. John Wheeler, Pittsfield, Vice-President; Dr. D. S. Adams, Manchester, Treasurer; Dr. G. P. Conn, Concord, Secretary; Dr. A. P. Richardson, Walpole, Anniversary Chairman; Drs. A. H. Crosby, C. R. Walker, Concord, and Dr. G. D. Towne, of Manchester, Executive Committee.

A board of ten Censors and twenty Councillors was elected, and a programme for reports and papers was an-

nounced for the session of 1884. Dr. J. S. Billings, U. S. A., Washington, D. C., and Dr. J. H. Mackie, of New Bedford, Mass., were elected honorary members of the Society.

This was followed with discussions and the report of cases until afternoon, when the Society adjourned to meet again in this city on the third Tuesday of June, 1884.

OREGON STATE MEDICAL SOCIETY.

Tenth Annual Meeting, held at Portland, Oregon, June 13, 14, and 15, 1883.

(Special Report to THE MEDICAL RECORD.)

ADDRESS OF WELCOME—PREVALENCE OF CRIMINAL ABORTION IN OREGON—THE QUESTION OF OPERATION IN MORBUS COXARIUS—OCULAR AFFECTIONS IN CONSTITUTIONAL DISEASES—ELECTION OF OFFICERS—SUBNITRATE OF BISMUTH AS AN ANTISEPTIC—DENTITION AND AFFECTIONS RESULTING THEREFROM—GUNSHOT WOUND OF STOMACH—SPONGE-GRAFTING.

THE Society was called to order at two o'clock, President DR. C. C. STRONG, in the chair.

THE REV. DR. F. R. MARVIN being present was invited to the platform and opened the meeting with prayer.

DR. C. H. WHEELER then welcomed the Society to Portland in a very appropriate address.

DR. S. E. JOSEPHI, of the Oregon Hospital for the Insane, extended to the Society a cordial invitation to visit that institution during the session.

The Executive Board having reported favorably, Drs. Jas. F. McCormac, Marshfield; Hannibal Blair, Albina; J. C. Whiteaker, Portland; John S. Stott, Hillsboro; Otto S. Binswanger, Portland; J. A. Fulton, Astoria; Chas. E. Bebee, Goldendale; G. Cooke Lane, Portland; D. Raffety, East Portland; A. G. Avery, Portland, were elected active members of the Society. Rev. F. R. Marvin, M.D., was elected an honorary member.

DR. G. M. WELLS then called the attention of the Society to a case of parametric abscess from which he had taken that morning a large amount of pus. The doctor stated that his principal object in speaking of the case was the fact that it was one of many similar cases which came under his observation as the result of criminal abortion, which was practised in this city to an alarming extent, and hoped the Society might take some steps in the direction of suppressing the practice.

DR. B. A. OWENS then presented a case of hip-joint disease for examination, and asked the Society to recommend a course of treatment. The disease was in the beginning of the second stage, and from the examination of pus aspirated from an accumulation just below the great trochanter, it was evident that the bone was diseased and that the process of exfoliation was established. The question of treatment elicited an interesting discussion, Drs. Wells, Saylor, Blaney, Tyler-Smith, and Owens recommended excision of the bone, while Drs. Givens, McKenzie, Dodson, Lane, McKenzie, and Fraser advised rest with extension and counter-extension of the limb, etc.

Meeting called to order at 10 A.M. June 14th by C. C. STRONG, M.D., in the chair.

DR. F. B. EATON read a paper entitled "Diagnostic Importance of Ocular Affections in Constitutional Diseases." The paper was discussed by Drs. McKenzie, Givens, and Lane.

The time fixed for the election of officers having arrived, the Society took up that order of business, the election resulting as follows: *President*—Dr. W. H. Saylor; *Vice-President*—Dr. J. W. Norris; *Secretary*—E. P. Fraser; *Member of the Executive Board*—Dr. C. M. Wells.

DR. SAYLOR then presented a case showing the favorable result of an operation of excision in hip-joint disease.

DR. HOLT C. WILSON read a paper on "Antiseptic

and Aseptic Surgery," in which he called special attention to the use of subnitrate of bismuth as an antiseptic. The paper was discussed by Drs. Watkins, Givens, Eaton, Fulton, and J. R. Smith.

DR. JOSEPHI presented a paper entitled "The Present Condition of Insanity throughout the World," giving very valuable statistics on the subject.

DR. B. A. OWENS read a paper entitled "Dentition and Affections Resulting therefrom."

The Society then selected the following subjects for special consideration at its next annual meeting: Diseases of Joints; Headaches; Tuberculosis; Pathology of Pregnancy; Uses of Bismuth; Typho-Malarial Fever.

Meeting called to order at 10 A.M. June 15th, President C. C. STRONG, M.D., in the chair.

A paper was then read to the Society by DR. J. F. McCORMAC, describing a case of "Gun-shot Wound of the Stomach with Recovery."

DR. SAYLOR then read the report of some cases of sponge-grafting in chronic ulcers with marked success.

DR. C. C. STRONG, President, then read his address on retiring from the chair.

DR. W. H. SAYLOR, President-elect, was conducted to the chair and read a short inaugural address.

On motion, a committee was appointed to draft resolutions in regard to deceased members.

Portland was selected as the place of the next annual meeting.

There being no further business the Society adjourned *sine die*.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE NEW OUT-PATIENT DEPARTMENT AT ST. MARY'S HOSPITAL—THE NEW LAW COURTS—DR. OLIVER'S TEST-PAPERS AT THE CLINICAL SOCIETY—THE ARMY MEDICAL INQUIRY.

LONDON, June 13, 1883.

THE new out-patient department of St. Mary's Hospital has been opened. It is a decided improvement on the old rooms, which occupied the basement and were mainly lighted by skylights. The new rooms are lofty, well lighted, and fairly well ventilated. For the latter purpose Tobin's tubes are placed in every room, and a large extraction shaft surmounts the central hall. The outer walls have, here and there, bricks perforated with conical holes—the large end innermost—the object being to bring air in without draft. All the passages have their walls covered with glazed bricks, which will conduce greatly to cleanliness. Close stoves are at present employed for warming the rooms. It seems a pity hot water or warm air was not employed. Greater uniformity in the temperature would have been thereby attained. The department is connected with the main building by a short flight of steps, which is roofed in, but not closed in at the sides. This seems a pity, and cannot but prove unpleasant in winter. It is also a pity that the new building has not been so arranged as to enter on the level from the main corridor of the hospital. As it is, on entering the hospital you *ascend* a short flight of steps to the main corridor, pass along it, then *descend* half-a-dozen steps to the new out-patient department, and then *ascend* a flight of steps to the consulting-rooms. The patients go *down* steps from the street, then *up* a flight to see the doctors, then *down* again to the dispensary, and finally *up* a few steps into the street.

Architects never seem to consider stairs a disadvantage. At the new Law Courts, the judges—most of whom are old men—have to ascend about forty steps to their rooms. No lifts have been provided. The Courts are also said to be damp, and cases of illness are stated to have occurred among the officials.

At the last meeting of the Clinical Society Dr. George Oliver, of Harrogate, demonstrated his method of detecting sugar in the urine by means of test-papers charged with carmine of indigo and carbonate of soda. One of these papers placed in a test tube with a little water and heated gives a blue solution. If a drop of saccharine urine be added first a play of colors ensues on heating—purple, red and straw, successively. On shaking, the colors reappeared in the reverse order. Heating again brought them out again. A confirmatory test was applied by dropping in a paper charged with corrosive sublimate while the indigo solution was still hot, which immediately gave rise to a blackish green precipitate. Non-saccharine urine merely gave a transparent green solution with the mercuric paper. Dr. Oliver claims that his method will detect sugar in any proportion in the presence of albumen, peptone, pus, blood or bile; that it gives no play of colors with uric acid; and that it is cleanly and portable. Dr. Oliver has not obtained the characteristic play of colors with the indigo test-paper with any other substance but glucose.

The army medical inquiry has excited considerable interest. The report is not yet published, but proof-sheets have been communicated to *The Times* and an article on the subject has already appeared in that paper. A memorandum on the subject by Sir W. MacCormac, which is to be published as an appendix to the report, also appears in the current number of the *British Medical Journal*. Some of the charges against the medical department will probably fail to be sustained, whilst others refer more properly to the commissariat and military departments. The medical department will, though, doubtless be made the scape-goat.

As an illustration of the repute in which the profession is held by the Government, it may be remembered that, when votes of thanks were passed by both Houses of Parliament to the officers engaged in the Egyptian campaign, the name of the chief medical officer was not included. The medical profession has always been treated badly in the public services. The army, naval, Indian, and convict medical services have each in turn been the scenes of shabby treatment to medical men, so history is but repeating itself now. Lord Wolseley's evidence seems particularly unsatisfactory and at variance with his statements in public despatches at the time of the alleged shortcomings. Lord Wolseley stated that he actually went into the hospital at Ismailia and grumbled at the medical officer because the patients were not supplied with better bread. This gentleman replied that he had complained to the commissariat, but his lordship seemed to think that it was the duty of the medical officers to go out into the bazars and buy bread themselves.

The Parkes Museum of Hygiene was reopened on Saturday morning, May 26th, at its new premises in Margaret Street. Speeches were delivered by Sir Charles Dilke, the Duke of Albany, and others. In the new museum many of the exhibits have the great advantage of being shown in action; for instance, the different varieties of water-closets have had a water supply laid on, and have been connected with the drains, so the way in which the flushing action takes place can be observed.

THE LILY OF THE VALLEY IN HOMŒOPATHY.—Some Western homœopaths have got hold of convallaria, and having read all that scientific medicine has to say about it, are quietly appropriating the drug themselves. Dr. Hall recently read a paper on the subject before the Western Academy of Homœopathy (the feebleness the association the more high-sounding the name), at Madison, Wis. Without giving credit to any one but Dr. d'Ary, he tells all about the drug, recommending it in small and large doses. In palpitations and irritable heart he gives one-thousandth to one-tenth of a drop with great success.

OUR PARIS LETTER.

THE ALLEGED WONDERFUL PROPERTIES OF COPPER.—
SO-CALLED SYPHILITIC TEETH NOT PECULIAR TO
SYPHILIS.

PARIS, June 12, 1883.

THERE are two men in Paris who have the same hobby, though they do not ride it in the same direction. That hobby is copper, and they are both known to your readers. Dr. Burq has for many years maintained that copper was a specific for cholera, for which it should be prescribed, not only for the cure of the affection, but it should be used continually as a prophylactic. Dr. Burq founded his theory on the fact that those employed in the manufacture of copper articles enjoyed a remarkable immunity from the disease. Arguing from this standpoint, Dr. Burq was inspired with the idea that copper would have a similar beneficial effect on typhoid fever. He made particular inquiries, and ascertained that during the recent epidemic of typhoid fever in Paris there were only two deaths among the manufacturers of copper articles. Moreover, he learned that in a copper manufactory in which there were from three hundred to four hundred workmen, only one death occurred during the last sixty years from infectious disease, and that death was from small-pox. From this Dr. Burq formulated the following conclusions, which he submitted recently at a meeting of the Biological Society: First, there exists an incompatibility between the salts of copper and the microbes of infectious diseases; second, in anticipation of the preventive inoculations of infectious diseases as proposed by M. Pasteur, one could be protected by the administration of large doses of the salts of copper, the innocuousness of which has been shown by M. M. Ducor and Galippe. Dr. Galippe, it will be remembered, has for some time endeavored to prove the innocuousness of copper, but people both in and out of the profession are rather sceptical about this, and remain under the old impression that copper is a powerful poison. Dr. Galippe lately submitted a paper at the Academy of Sciences in which he asserted that copper was found in large proportion in the nuts of the cocoa tree, from which chocolate is manufactured. It is therefore erroneous to suppose that the copper found in the latter substance is added to it for fraudulent purposes.

Another hobby is that of Professor Parrot, who sees syphilis everywhere, particularly in children in whom, according to him, rickets is one of the manifestations of hereditary syphilis, and he has even discovered syphilis in prehistoric skulls. Professor Parrot is the great champion of France of Hutchinson's interpretation of the lesions of the teeth, which the latter author described as being characteristic of syphilis, but at a recent meeting of the "Société de Chirurgie," where the subject was fully discussed, Hutchinson's theory about syphilitic teeth and Parrot's notions respecting the relation that exists between syphilis and rickets did not meet with much favor. Dr. Magitot, a well-known dentist, as principal speaker on the occasion, declared that from his experience the lesions known as Hutchinson's were not at all peculiar to syphilis, as they are found in children who are not syphilitic, but who are the subjects of other pathological conditions.

The same lesions may also be seen even in animals. He also referred to several cases in which adults bearing these lesions have contracted syphilis, which would have been impossible if they had been already syphilitic. According to Dr. Magitot the following are the real characters of syphilitic teeth: They are small, deformed, irregular, and slow in making their appearance, but he rather startled his hearers when he declared that the dental lesions known as Hutchinson's were due to infantile convulsions. Among other speakers, all of whom rebutted the idea, Dr. Desprès asserted that he had seen several children bearing the dental lesions referred to, but who have never had neither syphilis nor convulsions. Dr. Desprès added

that he had met with one case in a child, whose mother had just recovered from typhoid fever when she became pregnant, and another who was fed artificially bore these lesions. These two cases would seem to suggest that the malady or state of health of the parents would have a certain influence on the regularity of the evolution of the teeth in their offspring.

"MEDICAL EDUCATION IN CANADA AND CHURCH INFLUENCES".

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Having read an editorial, published in your journal of April 28th, on "Medical Education in Canada and Church Influences," permit me to say that the writer is under a complete misconception as to facts. With the sole object of placing you right on the question at issue, I take the liberty of addressing you.

To begin, you say that the number of students attending Laval University, of Quebec, "became fewer and fewer each year." Now, a reference to the annual announcements issued by the University prove the exact opposite; consequently, the reason advanced by you for the establishment of the Laval Branch in Montreal is not the right one.

Laval University was founded in the city of Quebec at the request of all the bishops of this province, and with the understanding that *there should be no other Catholic University established in opposition to her*. Later on Monseigneur Bourget, then Bishop of Montreal, supported by the professors of the Montreal School of Medicine, in affiliation with Victoria University, of Coburg, applied to Rome asking for a Catholic University in Montreal, giving as a reason that the absence of a university forced the school into an affiliation with Victoria, and that this affiliation with a Protestant university was scarcely in accordance with Catholic precedent, and was absolutely dangerous from a Catholic standpoint. Rome having long ago decided that one Catholic university in the Province of Quebec was sufficient, and knowing that Laval had been founded on this understanding, in response to this application of the bishop and professors, issued the now famous decree of February, 1876, and it was in obedience to this decree that the authorities of Laval established their branch in the city of Montreal. In the year following faculties of theology, law, and medicine were formally organized, and all the professors of the School of Medicine, affiliated with Victoria University, received appointments in the new medical faculty of the Montreal Branch of Laval University.

Shortly afterward, owing to a dispute as to details, a majority of these same professors separated from Laval to continue their school of medicine under its old auspices. So much for the origin of Laval University in Quebec and its branch in Montreal.

I now come to your remarks on the legal aspect of the question.

No action was ever taken by the Montreal School of Medicine to the Privy Council in England. An action taken before the Superior Court in Montreal against the University of Laval, some three years ago, may be considered as discontinued, and as a matter of fact was never brought up in open court at all. The School of Medicine did, however, take the legal opinion of Sir Farrar Herschel in London, and that is all.

The University of Laval, on the contrary, in order to set aside all doubts as to the legality of her position in Montreal, appealed to the Parliament, and in spite of every opposition on the part of the School, a bill was passed by the Legislature of the Province of Quebec to set aside all doubts on the subject. This bill received the sanction of the Lieutenant-Governor, and notwithstanding a further factious opposition by the School, the bill was maintained in Ottawa by the Governor-General.

Therefore, the Montreal branch of Laval University is not, as you erroneously infer, an illegal body. On the

contrary, its diplomas are strictly legal. The "College of Physicians and Surgeons" of this Province has consequently never had the slightest reason for withholding his license from bearers of the Laval diploma.

Furthermore, Rome, seeing that they who had made representation in the first place that the affiliation with a Protestant university was dangerous to the faith of their Catholic students still continued the said affiliation, and in addition did all in their power to injure the branch of Laval opened in Montreal, issued another decree, that of February, 1883, requiring the immediate and complete fulfilment of the previous decree of 1876, and in addition, ordering that all efforts to injure the University of Laval and its Branch, should forthwith cease, and that all good Catholics should aid in every way possible.

In order to conform to this decree, acknowledged by all Catholics as obligatory, the Bishop of Montreal has issued his mandate to the Sisters of the Hôtel-Dieu, to receive the Laval professors and students into their hospital, in place of those of the School of Medicine in affiliation with Victoria.

The Sisters do not refuse to obey their Bishop, as you assert, on the contrary they have transmitted his order to the professors of the School, declaring at the same time their intention of abiding by his mandate.

The School again in its turn appealed to all the Bishops of the Province in Council assembled. The Archbishop of Quebec, the Bishop of St. Hyacinthe, and the Bishop of Pembroke were charged by the Council with the execution of the Papal decree, and are at the present moment in Montreal, in furtherance of this object.

Hoping you will, by the publication of this letter, correct the many errors into which you have doubtless quite unintentionally fallen, I beg to subscribe myself, Mr. Editor,

Your obedient servant,

E. P. LACHAPPELLE, M.D.,

Secretary Med. Fac. Univ. Laval, Montreal, and Treasurer of Coll. Phys. and Surg., Prov. of Quebec.

MONTREAL, May 29, 1883.

[We have considered all the points in the above letter of Dr. Lachapelle, and must say that he has not convinced us of any material incorrectness in our editorial of April 28th on the above question. It is useless for Laval to assume any other reason for coming to Montreal than that of extreme poverty in Quebec. It is an accepted truth that for good prospects in teaching facilities we require an increasing commerce and population, which bring with them hospital material and wealth to maintain it: and Quebec, unfortunately, has been losing ground in both of these respects instead of increasing. This is an acknowledged fact throughout the whole province. It is quite true Laval obtained the passage of a bill through the Quebec Legislature to give the established branch of its university in Montreal the semblance of legality, but it must not be forgotten that the local government of Quebec has not the power to set aside the enactments of the imperial government, and upon this point rests the illegality of Laval's position. We also understand that the passage of such a bill in Quebec could not have been a very difficult matter, as the will of the Archbishop of Quebec is law in such matters, and the government is simply his mouthpiece. The acceptance of Laval's degree by the College of Physicians and Surgeons as a legal document may be accounted for by the majority of its members being also under the influence of His Grace.—Ed.]

SIR HENRY THOMPSON ON CIGARETTE SMOKING.—In a letter to *The Lancet*, Sir Henry Thompson states that if cigarettes are smoked in a holder with a bit of cotton-wool interposed they are less injurious than cigars or pipes. Smoked in the ordinary way, held between the teeth and smoked nearly to the end, they may be most hurtful.

MIDDLE GROUND ON THE CODE QUESTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I think that the following editorial from the *New York Herald* of June 25th, one very similar, which recently appeared in the *New York Times*, and others, which have appeared in various papers of influence in different parts of the country, cannot be seen by too many of those of our profession who are keeping up this, to most people, senseless quarrel about a "code":

"A report comes from a town in Wisconsin that a little girl was thrown from a carriage and had her skull fractured. An allopathic doctor was called in and treated the case until the arrival of the family physician, who was a homœopath. Soon afterward the young patient grew worse and serious symptoms were developed, which required special surgical treatment. As the homœopath made no profession of surgical skill the allopath was recalled; but, on finding the former in attendance, obstinately refused to have anything further to do with the case, on the ground that he could not 'consult with a homœopath.' Notwithstanding the earnest entreaties of the anxious parents and the proffered withdrawal of the family physician, the allopath deliberately abandoned the child in its critical condition and, so far as he was concerned, left it to die. He was 'a regular,' he said, and 'must observe our Code.' Nothing was then left to be done but to telegraph to Chicago for a surgeon, who fortunately arrived in time to save the young life.

"For the sake of common decency it is to be hoped that this barbarous illustration of the operation of 'the Code' is an exceedingly rare one. Yet it is but a logical effect of the practical working of a theory which subordinates the instincts of humanity to inhuman notions of medical ethics, and holds the saving of human life of less consequence than the heartless subserviency to a petty system of professional red tape. If the medical profession itself does not soon reform its ridiculous and unmanly 'Code,' then it may be well to inquire whether the law cannot prescribe a proper penalty for such offenders as the Wisconsin 'regular.' In case of the death of a patient under such circumstances trial of the offending doctor for manslaughter might have a salutary effect."

This discussion is rapidly losing us the respect and friendship of the press and of thinking people outside the profession, and transferring it, to a certain extent, to the homœopaths, who have not rendered themselves liable to the same obloquy. Our enemies could not have devised anything more injurious than this. It is useless for us to attempt to explain to what will soon, I fear, be considered an outraged public, the *status* of the question from our standpoint. They cannot and will not understand our position or our explanations. There are fools in all professions, and the "Code" is more apt to develop such instances as the above, among *them*, to the damage of the profession, than to prevent harm by its stringent regulations.

The "Code" refers to a good many points, but the discussion, with unanimous consent, seems to have narrowed itself down to one point—consultation with homœopaths. Well, consultation with homœopaths thirty years ago, was an absurdity, and no respectable physician thought of it. But the homœopathy of the present day is quite a different affair, and consultation with a well-educated homœopath may be as pleasant to the physician and as profitable to the patient as with one of the regular school. Dr. Flint, the honored exponent of the old Code, would have us believe that one who consults with a homœopath connives at fraud. He says, in substance, let him drop his special designation and call himself simply physician, and one may consult with him. Well, how many signs do we now see in New York with the designation homœopathic on them? Very few; they are rapidly disappearing. The better class of homœopathic physicians are repudiating the designation, so far as it indi-

cates exclusive belief, in a particular dogma, or reliance on any exclusive system of practice, either *similia similibus curantur*, or the employment of infinitesimal doses. They seem to be ambitious to be called simply physicians, while we, on the other hand, for some time past, at least, have been gradually admitting that the practice of homœopathy is not *all* fraud or humbug; and that in some cases medicines do act on the homœopathic principle, and also that very minute (if not infinitesimal) doses of many of our drugs when thoroughly triturated in the machinery of the homœopathic pharmacists, act in many cases far more pleasantly and satisfactorily than in their crude form. Witness Kinger's works, now so popular, and the frequent articles in our journals on minute doses, from the pens of some of our ablest practitioners. The absurdities, and worse, the falsehoods of many of the earlier homœopaths, claiming impossible successes, so disgusted us that we naturally scouted the whole matter as fraud and trickery, and did not until of late years give, if we have yet given, the system a fair clinical test. Our codes, in all the societies with which I have had any acquaintance, have been a failure. Let us sweep away all codes as the easiest solution of this very serious disagreement in the profession. If a physician should so far forget his self-respect and the dignity of his profession as to consort and consult with irregulars and disreputable individuals, made M.D.s perhaps by the legislature, he would soon find that he had seriously compromised his standing with his colleagues, and could be summoned before the bar of his medical society on the charge of conduct unbecoming a physician and gentleman, and punished just as effectually as if the Code were in existence—indeed, I think more so.

Our younger and rising men, if they would not lose the esteem and confidence of their friends outside of the profession, must stir themselves, and with the aid of their elders who are not too old to learn new things, abolish codes as so much rubbish of a by-gone age. Let the New Code men abandon their position, and the Old Code men theirs, and meet on a common platform on which all gentlemen belonging to the great profession of *medicine*, not homœopathy or allopathy, ought to be able to stand together.

HARMONY.

THE NEW YORK POST-GRADUATE SCHOOL AND THE ABUSE OF MEDICAL CHARITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In a letter signed "Itis," and published in a recent number of your journal, under the heading "Polyclinics, Post-Graduate Schools, etc., and their Relation to the Medical Profession," the writer descants upon "the perversion of charity and the development of pauperism among patients who are amply able to pay," and protests "against any institutions whereby *his* (our) means of gaining a livelihood are materially and even seriously compromised."

As the well-defined charges and statements of the letter may create some misapprehension in medical circles, it may be proper to state that the New York Post-Graduate Medical School has from the beginning of its career, persistently advocated, and rigidly adhered to a high standard in the dispensation of its charities, to which, doubtless, is largely due the material support it has secured from the physicians of this city and its environs. But the relations of the patients to the school can best be shown by its printed rules, which are to be found on the cover of each prescription-book of the Institution.

Rule No. XI. says: "Any person applying for medical or surgical relief, who, in the opinion of the Secretary, is able to pay a reasonable sum for advice and medicines, shall be so informed, and (unless it be a case of emergency) referred to private sources for them. No person who is able to pay a reasonable amount for both

advice and medicines shall be entitled to the benefits of this institution. The physicians generally shall have power to reject unworthy applicants." Nor is this all. Each patient is expected to pay for such medicine as is ordered by the physician, and the average price that has been paid for each prescription dispensed at the pharmacy of the School (based on the first one thousand prescriptions, and including those dispensed *gratis* to the absolutely impecunious) has been more than sixteen cents, an average price that would prove remunerative to many of our ordinary city druggists.

Individual opinions may differ as to whether the New York Polyclinic or the New York Post-Graduate School are necessary or "unnecessary," but it is a matter of fact, that medical men from far and from near in our country have seen fit to patronize them, and in sufficient numbers to place their finances on a satisfactory basis.

I am, respectfully yours,

THOMAS E. SATTERTHWAITE, M.D.,
Secretary of the Faculty.

213-215 EAST TWENTY-THIRD STREET.

"CHLOROFORM NARCOSIS DURING SLEEP."

THE article with the above title recently contributed to our columns by Dr. J. H. Girdner has called forth considerable comment. As a continuance of a discussion of the subject we group the following communications:

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Having read with interest the paper by Dr. Girdner on the above subject, I beg leave to take issue with the gentleman, having myself, in a number of instances, produced chloroform narcosis in children, administering the same while they were asleep and making my examination or operating without the child ever having been aware of the handling it had received. In one case I particularly call to mind, a child, six years of age, having hæmaturia in which a polypus was suspected, the child was anæsthetized upon six or seven distinct occasions for examination and operation, and after each sitting was left sound asleep, not knowing what had taken place when she again recovered consciousness. I have also had occasion to employ the anæsthetic during sleep in a number of cases while house-physician in the Mount Sinai Hospital in New York.

I am, yours, etc.,

L. E. BORCHEIM, M.D.

ATLANTA, GA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Before the evidence is all in, and the case submitted to the jury, I would offer the following as a fragment of "evidence" in favor of the possibility of bringing a sleeping person profoundly under the effects of chloroform without his first being aroused to consciousness. In 1856 I was requested by my then partner, Dr. I. S. Dolson, of Bath, N. Y., to see with him a case in which a bright boy, of about four years of age, in his play had fallen and received quite a severe wound of the face. To avoid an unsightly scar it seemed very desirable to carefully stitch the wound. Voluntary submission on the part of the child was found impracticable, and the mother was equally averse to the child's opposition being overcome by force.

At my suggestion it was decided to try the use of chloroform while the child would be asleep, to aid us in our work. Accordingly, late the same evening, we again visited the patient, and found him in the condition desired.

Without delay I stole quietly into his room, the lights being well turned down, and by gradual approaches I brought a napkin saturated with the anæsthetic to the child's face without exciting cough or the contraction of a muscle. In a few moments the patient was fully under its influence, and the little operation satisfactorily performed by Dr. D. The child slept quietly through the

night, and wondered the next morning how he came by the big plaster on his face.

This was the first and last attempt of the kind I ever made; and had no other thought than that it would be practicable in all cases, until the late prominent discussion of the subject in THE RECORD. Success in this direction is only attained by the most careful and deliberate manipulation on the part of experienced physicians, and even then it seems that some fail, and I have little confidence in the sensational newspaper reports of burglaries committed after the inmates of dwellings had first been "chloroformed" by the robbers.

Can any one give us a well-authenticated case of this kind?

H. C. MAY, M.D.

CORNING, N. Y.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Observing in your issue of May 26th, Dr. S. Murill's report of a case of "Chloroform Narcosis During Sleep," stimulates me to write of a similar case which occurred in my own practice.

April 30, 1871, I was attending Walter McF—, aged four years, for morbus coxæ. An abscess having formed, and the little fellow having been under treatment for some time, very naturally had become exceedingly sensitive and irritable. In order to open the abscess, I finally concluded to try to transfer him quietly from a natural sleep to a chloroform sleep, and requested the assistance of Dr. M. A. Halsted. We were quite successful in the first attempt, but, another abscess having formed, we were not so successful in a subsequent attempt.

We hear much more about "chloroform narcosis during sleep" through the lay press than we do through the medical journals; but it is evident that Dr. Murill's case and mine, and probably many others not reported, prove that such a thing is not impossible.

W. F. MORGAN, M.D.

LEAVENWORTH, KANSAS.

CONCERNING MEDICAL DEGREES IN GREAT BRITAIN.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: If your London correspondent will refer to *The Lancet*, May 19, 1883, page 870 (and throughout that journal, *passim*), he will see a critique on a translation of a German work on practical anatomy, by Donald Macallister, M.B., who, in this article, is always spoken of as *Mr. Macallister*. What then becomes of his statement that I am incorrect in saying that an M.B. is not *entitled* to be called Doctor? I maintain that he is not. He is sometimes called Doctor in *pure courtesy*, and nothing more, as licentiates of colleges of physicians are likewise.

I do not *at all* forget that the word physician is used in a different sense in England from what it is in America. Your correspondent seems to think that no one is a physician but a consultant. But any one licensed to practise medicine is a physician, according to common sense and the ordinary meaning of the word. He says the possession of L.R.C.P. does not make the holder of it a physician. Then there is no meaning in language. You will see from the following extracts from the register of the King's and Queen's College of Physicians in Ireland how far his remarks apply to the licentiates of that body:

"Every candidate before admission as a licentiate solemnly declares . . . that he will not engage in any trade . . . nor compound nor dispense medicine for sale. If he be an apothecary he must, previous to examination, *surrender the apothecary's certificate*. . . By ancient usage in this country, analogous to 'Rev.' in the case of a clergyman and 'Esq.' in the case of a barrister, the title of 'Dr.' has been applied to a *physician* as distinguished from that of 'Mr.' to a surgeon."

In the above extract the term physician is obviously used to denote one who holds the license of the college.

and when he receives it the college causes to be put in the newspapers an advertisement to the effect that ———, having been duly examined, has been admitted a licentiate and received authority to practise as a *physician*.

I did not say that "gentlemen who are only M.B. are addressed as Mr." What I said was "the M.B. *can* only call himself Mr."—a very different thing. Your correspondent should quote more carefully. If those M.B.s who, according to him, modestly *assume* the title of doctor continue to do so after the new bill becomes law, they will render themselves liable to a penalty of £20 (*vide Lancet*, May 12, 1883, p. 849).

Apologizing for trespassing so much on your space, especially as the whole subject is *vox et præterea nihil*,

I am, sir, yours faithfully.

N. V. D. PARKS, B.A. Dub., L.K.Q.C.P.I., etc.

ASHTON, R. I.

THE LEGAL STATUS OF THE PROSPECTIVE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: There is a vital point, it seems to me, on which the Board of Trustees of the American Medical Association, to which is entrusted the publication of its journal, failed to give information. If the journal is to assume the place claimed for it, its publication, with all that appertains, involves a very large financial enterprise, such as can only rest securely upon a solid legal basis. So far, if that body is an incorporated one, I have not been able to learn when or where it became such. If it is not, it seems to me the so-called Board of Trustees, consisting of a member from each State, and appointed to start and conduct the journal, has no legal existence whatever; that they utterly lack the power to make the association or its members financially and legally responsible for its acts; and that as such trustees they can neither sue nor be sued.

I write for the purpose of calling attention to this matter, fearing we may get into a muddle. Very likely, before the enterprise is on its feet, it will be found best to have the association incorporated, or to form a joint-stock company, under the statutes of the State in which the business is to be transacted. In such a case it will probably be found that the trustees must live in the county or State where the business is executed, and that a board with a member from each State is not practical. It may be that I am alone as to my ignorance in this matter, but I suspect there are many others who would like information on the subject.

J. W. HAMILTON.

COLUMBUS, O., June 12, 1883.

A PERFECTLY DEVELOPED MALE CHILD WITHOUT A PLACENTA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Thinking that a short history of this case may be of interest to many of your readers, and desiring to learn from them if any similar case has occurred in their practice (having searched the text-books in vain), I take the liberty of requesting space in your valuable journal for its insertion.

November 14, 1882, I was summoned to Mrs. C——, a well-formed and healthy woman, aged thirty-eight, a primipara.

Found the patient suffering from labor pain; pulse, 120; some vomiting; respiration rapid, and considerable cedema of the lower extremities. Vaginal examination revealed slight dilatation of the os, the vertex presenting. A specimen of urine was obtained and examined for albumen with negative results. Previous history of patient very good, having menstruated at the age of fourteen, and continued to do so regularly without pain until fecundation occurred nine months previously.

The pains being unsatisfactory, I left the patient, say-

ing I would return soon. At 11.30 A.M., about one hour after I left the sick-room, I was called in great haste to the patient, messenger saying she had a fit. Arriving at the bed-side found her in a very violent convulsion, which I learned was the second in half an hour.

Inhalations of chloroform were resorted to, which had the effect of modifying the severity of the spasm, for the time at least; full doses of bromide of potassium and chloral were administered, but without effect; the convulsions returning about every twenty minutes. Repeated efforts to dilate the os uteri failed, Barnes' dilators and the douche being frequently applied in vain, the uterus being anteverted, and the os extremely rigid. At 2 P.M. a hypodermic injection of sulphate of morphine combined with atropine sulphas was administered, the bowels having been previously moved.

A marked diminution of the spasms immediately followed the injection, the convulsions not returning up to 4 P.M., but the patient remained unconscious from the first convulsion. At 4.30 P.M. had her thirteenth convulsion. Morphine was again administered hypodermically, but as cedema of the lungs set in and the respirations reduced to 14 per minute, the morphine was suspended and the convulsions returned, the patient slowly sinking. At 5 P.M. a consultation was held, when the case was deemed hopeless. All efforts to dilate the os had to be abandoned. Distinct movements of the fetus being observed up to 5 o'clock P.M., a request was made to remove the child by Cæsarean section, but was refused. At 6.30 P.M., pulse 100 and feeble; respiration, 17; temperature in the axilla, 99.8°; patient rapidly sinking until 7.15 P.M., when she died after her twenty-second convulsion.

In about one hour after the death of the patient I was requested to take the child from its mother, some scruples on the part of friends demanding the separation of the child before interment. I accordingly commenced the operation by abdominal section. On reaching the uterus careful section of that organ was made, when a fetus was observed partly immersed in an inky-black liquid. An effort was now made to remove the child, but as something seemed to hold the fetus firmly, I inserted my hand into the cavity of the uterus, when I found the cord very rigid and unyielding. Having severed this obstacle, a perfectly formed male child, weighing about twelve pounds, was removed. Search was now made for the placenta, but without success. There was *no placenta*. The umbilical cord was found attached to the fundus of the uterus, and the length of the cord did not exceed four inches.

Permission to remove the uterus for examination was refused, and as every movement in connection with the operation was most earnestly and critically watched, I found it impossible to gain possession even of that portion to which the cord was attached. I did succeed, however, in dividing *this* particular part, but failed to observe any marked difference between it and that portion of the organ previously divided.

The amniotic fluid, which was excessive, measuring, I should say, over three pints, was exceedingly black, but in other respects normal.

VALENTINE BROWNE, M.D.

YONKERS, N. Y.

THE WAY OUT OF THE MUDDLE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In THE MEDICAL RECORD of May 19th is one of the most remarkable articles it has ever been my privilege to read, although accustomed to peruse and digest medical literature for more than twenty-five years.

It is head-lined "Inebriety from Obscure Physical Causes," by T. D. Crothers, M.D., Hartford, Conn. He states that he had previously written an article on the same subject. If the doctor had been familiar with drunkenness in its different degrees, and had seen its

every-day manifestations, he certainly would never have given expression to thoughts so widely at variance with the true inwardness of the matter. True, he claims to have discovered something new, if understood aright, and presents an array of cases, without names or places, to be used in an argument which proposes to remove the subject from the low plane of drunkenness, with all its horrible concomitants, to a level much more elevated and respectable, when the inebriate will be no longer known, as heretofore, but transformed, if not into a lovable, at least into a most unfortunate disease-afflicted person. No doubt this phase of inebriety would be quite acceptable to all excessive drinkers, who still have one spark of manhood dwelling in their bosoms.

It is the very thing every one of them would be pleased to have other people believe; and hence, every one, without a solitary exception, perhaps, would give some cause outside of the true one—a love of liquor—to account for their fallen, degraded condition. This is a part of human nature, and with the fallen ones of mankind it seems to be intensified. Who ever heard of an evil-doer, in any of the ways of transgression in this life, that did not have an excuse to offer for his waywardness—somebody or something to blame for the first false step? It has been ever thus since the day when father Adam so far forgot his manhood as to charge the responsibility to his helpless help-mate, and it doubtless will be to the end of time.

Now comes an excuse for the drunkard, more satisfactory to him than imagination could ever have pictured in his wildest flights of fancy.

Judging from the responses reported to have been received from A, B, and C, the doctor's former communication must have been a real godsend, enabling them to happily find their way out of what had heretofore been considered an inexplicable difficulty.

Were these views endorsed by the medical profession, it would give increased charms to the licentious indulgence of strong drink, and would afford all the protection and encouragement that the most ardent toper could desire. If they are unsound and without any foundation in truth, then they cannot be otherwise than detrimental to the best interests of every community, and should not be promulgated broadcast without a challenge from medical men, who view the subject from a standpoint as different as day is from night. Besides, it must be patent to every one that some unscrupulous doctor may take hold of this new discovery and ply it to his own selfish advantage in manufacturing a reputation and coining money, under the pretence of being a step in advance of his medical co-laborers?

Now every medical man is deeply interested in the truthful solution of this question; for, if the views set forth by the doctor are correct, then the profession was never so befogged and benighted on any subject since it had a beginning. This is a progressive age in all departments of learning. And in this race after something better and more perfect, medical science, in the past few years, has far eclipsed all others.

Still it must be admitted that only the threshold of medical research has been attained, and before the *Ultima Thule* of medical knowledge shall have been reached there can be no doubt that many things now held to be settled in accordance with truth will be set aside as unworthy, under a stronger and more searching light. With thoughts altogether impartial every new thing in medicine should have a fair consideration, and be weighed in the balance. Actuated by such motives, the attention of THE RECORD readers is invited to a careful study of the article in question.

Being reared, and having lived all his life in communities where drunkenness was no uncommon thing, the writer has had a most favorable opportunity for studying it under many different circumstances, and in all its phases, not theoretically, but practically and clinically. The caption, and many expressions throughout the doctor's article, to

say nothing of the main drift, sound very strangely indeed to one thus educated.

He says, for instance, there were "a number of cases in whom the causes of inebriety were unknown to the attending physician." How strange, when it cannot possibly be assigned to but one cause, the firm hold of the liquor habit. Further, that "the inebriate is not an enemy to society or civilization, but the victim of physical conditions;" "that inebriety is not a vice but a disease to be cured by treatment." Eight reported cases are given in the article published, to prove this proposition, and to place the subject "above the levels of the theories of reformers and clergymen."

With an eye single to the development of truth, and the general welfare of humanity, these cases have been thoroughly studied and analyzed several times, to see if there was really anything whatever in them; and a strict regard for what appears to be right and proper in the matter compels me to declare, unequivocally, that there is no difference between these reported cases and the thousands of others that have come under my own immediate notice, and about which information has been received from other sources. In other words, these cases portray a faithful picture of drunkenness, through all ages, from Noah's fall down to the present. Either all cases of drunkenness come from "obscure physical causes," or else these reported cases, like all the rest, must be attributed to the true cause, liquor, at first taken for its pleasurable effects, growing into a confirmed habit by repetition, and finally, getting away with them morally, mentally, physically, financially, and in every other way of which it is possible to conceive. No wonder the doctor's cases were changed from good, intelligent, moral, trusty persons, to characters directly the opposite. Such has been the history of intoxicants, where they have held sway, in all bygone time. When a person loses self-control, and gives way to strong drink, his character undergoes a complete change; and he is left an absolute wreck of former manhood, as every one must know who has much contact with drunkenness.

It was intended in the beginning to give an analysis of these reported cases, but time and space forbid. Neither is it necessary, since those who may see fit to read this article can refer to the number of THE RECORD indicated and judge for themselves. If they shall do so, the object of this article will have been accomplished.

It is said, "a whole volume could be filled with such cases," and this is not doubted in the least; for sixty thousand drunkards, including laborers, farmers, mechanics, merchants, lawyers, doctors, preachers, take their exit to the unseen world every year. And the question is asked: What shall be done to stay this terrible evil? What the means and remedies? The answer is given: Abstain from intoxicants of every description, as this is an infallible cure and the only one that has stood the test of time. To one who has lost self-control this is not an easy thing to do, by any means; indeed, there are many cases so entirely wrecked that it would be next to impossible for them to emancipate themselves, unaided, from this terrible habit, which holds with a force more vice-like than any other known.

This unfortunate class need help from their sober-minded brethren. They need treatment, it is true, but not to rid them of disease produced from "obscure physical causes." There is no sense in hunting for "obscure causes" when *liquor* is seen to be wrecking every one, on every hand, who dares to contest its strength.

The treatment they need, and the only kind that will meet the case, is to remove them beyond the influence of this mighty destroyer. How to do this, then, is the practical question, and one that comes home to every lover of his race. Many good people are now engaged in trying to solve this problem.

One way to meet the case, and it appears quite practicable, is for the general Government to establish one or more inebriate asylums in every State, or enough, at any

rate, to satisfy the demand. Let these asylums be regulated on the same plan as insane and other asylums, and receive their patients under the same rules as adopted by those institutions. Once within the asylum walls the toper would be free from his besetting vice, and under a little judicious toning up, in most cases, would soon realize the true state of the case—a thing not appreciated by him for weeks, may be for months and years before.

This treatment is in accordance with the doctrine, remove the cause and the effect will cease, and it certainly is a very sound, common-sense principle. Should other expedients be found necessary in connection with this place, the double-chloride-of-gold treatment—whatever that may be—could be tried. Not having had any personal experience with that particular medication, of course it is not herein endorsed, but it may be said, however, that reformed inebriates who were subjected to the treatment speak in the highest terms of its success. Very likely it acts on the principle of breaking a dog from sucking eggs by giving him, along with them, some tartar-emetic.

Another plan that will mitigate the evils of intemperance is to raise the liquor license so high as to practically strangle the traffic, and let it die a slow but tolerably sure death. Failing in these, the more radical plan of prohibition could be tried as a *dernier ressort*. The adoption of one or more of these plans, it is confidently believed, would meet the case, and save further trouble on the score of the "obscure physical cause" theory. It is hoped the questions have been answered, if not to the satisfaction of the doctor, at least in accord with the dictates of common-sense, which, after all, is a most excellent guide to follow, and will very surely lead one out of the inebriate muddle.

BROWNSVILLE, M.J.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 23, 1883, to June 30, 1883.

SMART, CHARLES, Major and Surgeon. Assigned to duty in the office of the Surgeon-General, U. S. Army, and in addition to his duties in the Surgeon-General's Office will continue to serve as a member of the National Board of Health. S. O. 147, par. 8, A. G. O., June 27, 1883.

BIART, VICTOR, Captain and Assistant Surgeon. Assigned to duty as post surgeon at Fort Sisseton, D. T. S. O. 102, par. 1, Department of Dakota, June 13, 1883.

WINNE, CHARLES K., Captain and Assistant Surgeon. Assigned to duty as post surgeon at Fort Winfield Scott, California. S. O. 69, par. 1, Department of California, June 19, 1883.

WORTHINGTON, JAMES C., Captain and Assistant Surgeon. Assigned to duty at Canonmont, on the Uncompahgre, Colorado. S. O. 128, par. 4, Department of the Missouri, June 21, 1883.

EVERTS, EDWARD, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Oeur d'Alène, and assigned to duty as post surgeon at Fort Lapwai, Idaho. S. O. 81, Department of the Columbia, June 14, 1883.

STRONG, NORTON, First Lieutenant and Assistant Surgeon. Relieved from operations of S. O. 42, par. 2, C. S., Department of the Platte, and assigned to duty with Battalion of Infantry now on duty between Forts Thornburgh and Bridger, Wyoming. S. O. 83, par. 2, Department of the Platte, June 21, 1883.

To be Assistant Surgeons with the rank of Captain, after five years' service, in accordance with act of June 23, 1874: Victor Biart, William W. Gray, Louis Breche-min, Louis A. LaGarde, Junius L. Powell, Assistant Surgeons, June 6, 1883. A. G. O., June 25, 1883.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending June 26, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
June 26, 1883.....	0	11	61	4	87	39	0	0
July 3, 1883.....	0	7	74	6	91	20	0	0
<i>Deaths.</i>								
June 26, 1883.....	0	9	16	4	18	11	0	0
July 3, 1883.....	0	3	23	9	22	16	0	0

GOOD ADVICE TO TRAVELLERS IN NEED OF MEDICAL ADVICE.—Dr. C. W. Chancellor, in a recent letter from Geneva to the *Baltimore Day*, gives the following excellent advice to European travellers: "I feel I would be but ill acquitting myself of a duty were I to fail to administer an admonition to those of my compatriots who may one day journey into this land, and I hope they will take heed to what I say, for it is wholesome. I would strongly advise Americans who contemplate travelling upon the continent to be very chary of patronizing physicians recommended by *hotel or boarding-house keepers, concierges, porters, etc.*, etc., without first having inquired of their consul or their banker, or some friend as to the standing of the party recommended, for it not infrequently happens that these parties plot together exclusively as a matter of personal gain, and without any regard whatever for the well-being or interest of those whom they advise. It would be well for persons visiting Europe either to obtain the addresses of competent medical men in the various cities they propose visiting before leaving home, or on their arrival to get advice from some reputable person *out of business and above taking a commission*, otherwise they may have a tenth-rate doctor introduced as the 'former physician to the emperor,' the 'chief of the hospitals,' the 'doctor of the American Legation,' or some other high-sounding but fictitious title, and they may be left in his hands to be robbed, maltreated, and perhaps murdered. Travellers, in fact, should *make it a rule to take any other physician than the one proposed by a landlord or concierge or courier*, unless the medical man thus recommended be a *compatriot, or is endorsed by some disinterested person*; and they should *insist* upon having the doctor of their choice—if they have a choice—*really sent for*, taking no excuse for any delay or neglect in regard to the matter. There are reliable and *veritable* American physicians in nearly all the large cities of Europe whose addresses can readily be found by consulting the *Directory*, which is in the office of every respectable hotel, or by inquiring at the nearest drug-store."

YATES COUNTY (N. Y.) MEDICAL SOCIETY.—At the annual meeting of the Yates County Medical Society, held in Penn Yan, on Tuesday, June 5th, the following gentlemen were elected officers for the ensuing year: *President*, Benj. L. Holt; *Vice-President*, D. M. Smith; *Secretary*, C. C. Harvey; *Treasurer*, John Maloney. The New Code was adopted by the Society unanimously.

ASYLUM SUPERINTENDENTS IN SESSION.—The thirty-seventh annual meeting of the Association of Medical Superintendents of American Institutions for the Insane was opened at Newport, R. I., June 26th. Dr. J. H. Collender, of Nashville, Tenn., presided, and thirteen States, the District of Columbia, and the Provinces of

Quebec and New Brunswick were represented. Dr. H. R. Storer, President of the Newport Medical Society; Dr. Foster Pratt, of Kalamazoo, Mich., and Dr. Darius, of the Willard Insane Institution at Ovid, N. Y., were presented to the Association. It was voted to invite the members of the medical profession of Newport and the vicinity, and the surgeons of the navy in that port to be present at the sessions of the Association. The following officers were elected: *President*—Dr. John P. Gray, of Utica, N. Y.; *Vice-President*—Dr. Pliny Earle, of Northampton, Mass. The president then delivered an address.

PLENTIFULLY SUPPLIED WITH DOCTORS.—According to a late estimate, Atlanta, Ga., has one physician to every 277 of its population, or one to every 156 of its whites, and one to every 121 of its colored population.

THE WARREN TRIENNIAL PRIZE.—We wish to draw attention to the Warren Triennial Prize for 1886. The subject for the present year was "Chronic Bright's Disease (parenchymatous and interstitial nephritis); "The Nature and Mutual Relations of the Derangements in the Circulatory and Secretory Organs." No award, however, has been made. Beyond that fact we are not informed as to the character or number of articles presented for competition. It is to be supposed that the terms were too restricted to draw out any great number of articles. No complaint can possibly be made as to the narrowness of the subject for 1886. The terms of the competition are such as to give the widest latitude to literary or scientific medical men, the prize being offered for a dissertation on "some subject in physiology, surgery, or pathological anatomy." The amount of the prize, \$450, and the wide range of subjects, ought to bring out work of a high order of excellence. This is, we believe, the largest prize offered in this country for general competition, and the physicians and surgeons of the Massachusetts General Hospital are, *ex officio*, the committee who have the matter in charge.—*Boston Medical and Surgical Journal*.

RESOLUTIONS ON THE DEATH OF DR. JAMES L. BANKS.—At the stated meeting of the New York Pathological Society, held June 27, 1883, the following resolutions were unanimously adopted:

Whereas, It has pleased God to remove from this world the soul of our late associate, James L. Banks, M.D.:

Resolved, That we sympathize with his family in the great loss which they have sustained.

Resolved, That we cherish his memory as that of an intelligent and wise physician, a kind and genial companion, and a conscientious, upright, and honorable man.

Resolved, That a copy of these resolutions be forwarded to the family of our deceased associate, and that they be published in the medical journals of this city.

ALFRED C. POST,
CHARLES K. BRIDGON, } *Committee*.
JOHN H. HINTON,

PHYSIOLOGY AT OXFORD.—The sum of \$50,000 has been voted for the erection of a physiological laboratory for Dr. Burdon-Sanderson at Oxford.

THE HARVEIAN ORATION was delivered this year (June 27th) by Dr. Habershon.

HYPOPHOSPHITES AND CHILDREN.—Dr. H. Cullimore thinks that the hypophosphites should not be given to children between the ages of four and seven if they are at all precocious and inclined to too much mental activity.

THE APPOINTMENT OF GENERAL ALEXANDER SHALES to succeed Professor Chandler as President of the City Board of Health is well received. It remains to be seen whether he will have the courage to protect the city's sanitary interests against the politicians.

THE OPENING OF THE JOHNS HOPKINS MEDICAL SCHOOL.—The trustees of the above institution design to begin some work in the medical school without wait-

ing for the hospital to be finished. With this purpose in view, Dr. Remsen has been designated Professor of Chemistry, Dr. Martin of Physiology, and Dr. Billings of Hygiene. A chair on Pathology will be filled soon, and lectures will begin October 1st.

THE PHILADELPHIA POLYCLINIC has with great enterprise secured an organ. The *Medical Register* will assume the name of *The Polyclinic* (with a y) and will supply the long-felt want for a monthly medical journal in Philadelphia.

THE EDINBURGH MEDICAL SCHOOL.—One thousand guineas have just been voted by the Town Council of Edinburgh, toward the building fund for the new Medical Department of Edinburgh University. These new buildings, which are nearly completed, are extensions of the old, and will greatly increase the advantages of the school.

A MODEST TRIBUTE TO PASTEUR.—The *Publicateur*, a journal published in the arrondissement of Meaux, contains the following poetical tribute to Pasteur: "M. Pasteur has the glory of being the first to bring knowledge out of mystery and make it irradiate through the Department of Seine-et-Marne; and every sheep which grazes upon the fields sings the glory of the master, and of science!"

TRICHINOSIS FROM EATING HORSE-FLESH.—Several Austrian journals report the case of a woman who suffered from trichinosis, caused, it is claimed, by eating horse-flesh. The subject is being investigated.

WANDERING LIVER IN A MAN.—At the meeting of the Society of Physicians of Vienna, June 4th, Dr. Felix Schwarz showed a case of wandering liver in a man, a very great pathological rarity. There have been only two cases in men and thirteen in women reported.

CHLORINE WATER IN DIPHTHERIA.—Dr. Caroline R. Conkey, of Watertown, N. Y., sends us a very enthusiastic description of the value of chlorine water in diphtheria. She writes: "In a late number of THE MEDICAL RECORD, Dr. Binz, of Bonn, is quoted as predicting that a remedy would surely some day be found which should prove as effectual a specific antidote to diphtheria as salicylic acid and quinine are to rheumatism and malarial fever. Such an antidote, I believe, we already possess in chlorine water.

"The importance of this agent was first brought to my notice by Dr. Marshall Calkins, of Springfield, Mass., to whom, I believe, the credit of discovering this application of chlorine water is due. Since then I have used it with unflinching success in every case of diphtheria that has come under my notice; and claim its absolute efficiency in curing the disease, provided, always, it can be dealt with in the first stage; *i.e.*, before the membrane extends into the larynx. My plan of treatment is as follows: Fresh chlorine water must be made every day according to the following formula:

R. Potass. chlor ʒ ij.
Acidi muriatici ʒ j.
Aquæ ʒ viij.

Into an eight-ounce bottle put the chlorate of potash; on this pour the acid, and cork as quickly as possible to prevent the escape of the gas. Add the water as hot as convenient, at intervals. Dose: tablespoonful in an ounce and a half of water, to be gargled and swallowed every half hour in a severe case.

"This dose may be swallowed without gargling, if, for any reason, that is impossible, and may be sweetened to render it palatable to a child. The interval between the doses may be lengthened, according to the discretion of the physician; in milder cases, being given every one, two, or three hours, as indicated. When the membrane extends into the nose or posterior nares, syringe with the same solution.

"This constitutes my entire treatment, and its success

is invariable. I insist upon the most nutritious diet. Every two hours nourishment in some form is given; and an even temperature of about 70° F. constantly maintained in the sick chamber, together with the most thorough ventilation."

The history of an illustrative case is given.

[While we have no doubt of the efficacy of chlorine water, it is necessary to remind our correspondent that chlorine water has been used before in diphtheria, and that the same claims which she makes for it have been made for a large number of other substances—and still diphtheria exists and kills. We are inclined to think that the case whose history is given was one of follicular inflammation rather than diphtheria.—ED.]

"MUSCLE *v.* BRAIN."—This popular heading aptly illustrates the misconception that prevails in result of ignorance of the laws of physiological development. It is a radical error to suppose that one part of the organism can be or ever is developed "at the expense" of some other. One part may be neglected while attention is exclusively directed to another part, but the fault does not consist in the overcare of the one, but in the neglect of the other. It is important to recognize this, because the phrase "muscle *v.* brain" would seem to imply that if we have muscle we cannot have brain. It is needless to remind those who understand the physiology of the higher animal life that no such alternative is presented. Each and every part of the body grows as it feeds. The point which is too commonly forgotten is that it feeds as it works, and in that proportion only. If any part is unexercised, it cannot possibly be nourished in such manner as to produce full growth and good health. In the training of youth it is especially necessary to bear this in mind. To produce good brain tissue there must be good brain exercise. The work done should not be sufficient to exhaust the organ, or the faculty of recuperation will be itself weakened and exhausted, and then the function of repair will lag behind the function of special activity, with the result of deterioration instead of progressive development. The work done should not, as a matter of fact, exceed such limits as regards quantity or quality as shall suffice to stimulate growth without exhausting. An overburdened or overworked brain cannot be healthy, nor can one that is underworked. Fatigue—we mean mental weariness—should not be incurred by the young; that is, during the period of development. The same rule applies to muscle cultivation. Full exercise without exhausting fatigue is the best, and, indeed, the only, stimulant of growth. Other things being equal, the best organism, the healthiest man, will be one in which both brain and muscle have been developed side by side by a process of educational training in which time and strength have been so utilized as to afford opportunity for growth in every direction. In what we call *mind*—i.e., brain function—as well as in physical strength or muscle function. After the organism has passed through the stage of growth, and its several parts have been finally formulated, there may come a time when muscular activity will so drain the strength as to impoverish the brain; but this state of matters is not reached until long after the educational period, and in a well trained organism it will never be reached at all.—*The Lancet*.

TRANSFERRED IMPRESSIONS.—Dr. Joseph A. Stillwell, of Brownstown, Ind., writes: "Your editorial on 'Telepathy,' of May 26th, reminds me of an experiment I made on a young man with delirium tremens. I was alone with him in the night. He had stepped out at the door to a vine trellis and was picking at the vines as if he was searching for something. I concentrated my mind on him with a strained effort. He raised from a partial stoop and asked me, 'What do you want?' He was about thirty feet away, and could not see me, nor did I make any noise. He was outside, and I in the house. His voice broke my effort for a second or two

when I renewed my attention with all the power of concentration I could command. He then in a sudden move and with some impatience asked me 'What do you want?' again, and turned and did take a step or two toward me, but left his purpose and lapsed off. I again gave him all my attention, when, like the others, just at its culmination, or what seemed to be, he gave me his sudden attention and said, with some vehemence, 'What are you calling me so much for?' This might have all *happened* only, but there was such an exact synchronous motion on his part in response to my intense action, that I have always felt that I reached his mind with only this mental act of mine. So much so, that, particularly when he said 'calling,' I felt an alarm come over me at my success that disqualified me for further effort. That was twenty-seven or twenty-eight years ago, when I was a medical student. Since that I have never met with a case and surroundings, that I thought justified a renewal of the experiment. And while I have never regarded it as concluding anything, now offer it in this connection."

BROKEN THERMOMETERS.—In the matter of broken thermometers, it is evident, we have raised a ghost that we cannot lay. Dr. G. L. Chapman, of Polo, Ill., writes: "I took my thermometer-case to a jeweler and got a small hole drilled through the bottom below the cavity of the case and tied a small black elastic cord securely to the *bottom* of the instrument and the other end to a safety-pin. The cord being attached to the *bottom* need not be more than twice the length of the case, and all disappears when the instrument is returned, if carried in the upper vest-pocket. The cord is lighter and cheaper than a chain, and does not wear the pocket; it does not require a metallic case and staple to secure its attachment, and is, I think, every way preferable."

AN ARRAIGNMENT OF AMERICAN VETERINARY SURGEONS.—A person who called himself a veterinary surgeon read a paper recently before the New York Farmers' Club, in the Cooper Institute, on the diseases of cattle and their treatment by veterinary doctors, whose methods he condemned. There were, he said, on the farms of the United States in June, 1882, 10,357,981 horses, valued at \$1,035,798,100; 1,812,932 mules, valued at \$181,293,200; 993,970 oxen, valued at \$49,698,500; 12,443,593 milch cows, valued at \$321,089,725; 22,488,590 other cattle, valued at \$562,214,750; 35,191,156 sheep, valued at \$527,867,340, and 47,683,951 swine, worth \$476,830,510, making a grand total of the value of dumb animals on farms in the country, \$3,154,821,125. This estimate, however, the lecturer considered by far too low, and he felt certain that the value of dumb animals in the United States was about seven billions of dollars, judging from the fact that some animals are held at \$50,000, as in the case of Damascus, just sent by John W. Garrett, of Baltimore, to the King of Italy. It is a disgrace to the nation, the orator continued, that there is not one legally chartered, organized, and established veterinary college in the country. Veterinary science here lies deep down in the ditch of ignorance, and the billions of dollars invested in animal property, as well as the animals themselves, are left to the mercies and wantonness of chance. The country is flooded with bogus diploma mills, several of which are in this city and other parts of this State. The speaker went on in the above strain, but failed to mention where the New York diploma mills are. It is understood that parties in this city do practically sell veterinary diplomas, and it is to be regretted that some definite facts were not given.

THE REGULATION OF PROSTITUTION.—The Municipal Council of Paris has lately addressed a letter to the Prefet, demanding the immediate confiscation of the Lourcine and Midi Hospitals, and the abolition of all the *maisons de tolérance* in the city and the Department. More recently they have voted the suppression of compulsory examination and treatment of women, and the abolition of the *police des mœurs* is under discussion.

INFUSION OF JEQUIRITY, OR LICORICE BEAN,¹ IN INVETERATE PANNUS,

WITH A REPORT OF SEVERAL SUCCESSFUL CASES.²

By EDWARD S. PECK, M.D.,

SURGEON TO THE EYE AND EAR DEPARTMENT OF THE NORTHWESTERN DISPENSARY; VISITING SURGEON TO THE OPHTHALMIC DIVISION OF CHARITY HOSPITAL, NEW YORK.

THE treatment of chronic granulations and sarcous outgrowths of the conjunctiva and cornea has always been a chapter of great interest to the physician and the patient. It has elicited the efforts of the best surgeons of every country where affections of the lids and eyeball prevail. In England, Germany, and the United States clinical work in this department has been displayed from different standpoints. Within the past few years the direction of applied effort has been in the establishment of an acute ophthalmia in lieu of the chronic proliferous catarrh of these structures. Chronic trachoma of the eyelid and inveterate pannus of the cornea are the result of the same pathological processes, differing only in location, but amenable to the same remedial agencies. It will seem a strange statement, that a structure of so low an organization as the cornea should be involved in the same pathological processes as one of so high a type as the conjunctiva. The cornea serves at once the function of confining and protecting the contents of the eyeball, and at the same time of refracting the first rays of light which are transmitted to the dioptric system; while the conjunctiva, rich in nerves and blood-vessels, serves merely as a lubricating and protective layer.

It cannot be denied that the inoculation of eyes with pus of various purulent ophthalmias has taken a more and more prominent place in ocular surgery. It is well known that the measure of success of the experiment is, within limits, determined by the activity of the inoculation. The experiments of Critchett, Lawson, and Bader in London, of Warlomont in Brussels, of Abadie and others in Paris, are entitled to highest praise in view of their successes; while, at the same time, the procedure will always be unpopular on account of the severity of the resulting inflammation and the natural repugnance of the patient and operator. Such experiments ought to be conducted only where a large number of trachomatous patients are aggregated, and when there is a small per centum of operations on the eye.

The report for 1881 of the Ophthalmic Division of Charity Hospital, Blackwell's Island, gives details of the favorable results of six experiments in inoculation, conducted by the author of this paper, the first case of the series having been presented as a contribution to this Society at its semi-annual meeting in 1881, and published in *THE MEDICAL RECORD*, July, 1881. Although I hold to the same opinions as to the efficacy of this treatment, as a *last resort* in all cases of inveterate pannus, yet I welcome the proposition of any new remedy, whether of the mineral, vegetable, or animal kingdom, which shall do away with the immense risks to the patient, the surgeon, and the nurse, in the establishment of an artificial purulent

ophthalmia. Various aromatic infusions, and hot medicated compresses have been used for this purpose, but they all lack intensity and duration. The present agent, which I show you in seed and infusion, is known by the botanical name of *abrus precatorius*, of Linnæus' classification; the seed is called licorice bean (not the licorice known in commerce); and in Brazil, where it has been used for years in ophthalmic practice, the seed is called *jequirity* (Fr.). The literature, all of which I have at hand, with the exception of the first article, written in 1867 in Brazil, is very meagre. This article was a brief memoir, in the Portuguese language, calling attention to the dangers connected with its use in eye-practice. I may add, that I hope not only to secure this initial article on the subject, but to interest the Secretary of State at Washington, with the view of procuring all the native medical and lay testimony upon the use of the infusion in ophthalmias in Brazil. If we have here an agent which, in the majority of cases, will prevent blindness and helplessness as a result of inveterate pannus, it is an object of popular charity to acquaint ourselves with its history, preparation, and application.

The infusion has been prepared of various strengths. That used in the Northwestern Dispensary and Charity Hospital, New York City, was prepared as follows: Take of the *fresh* seeds 32, or 3.2 gm.; macerate in 500 gm. ($16\frac{2}{3}$) of cold water for twenty-four hours; add 500 gm. of hot water; when cold, filter, and preserve in well-stoppered, dark-colored phials. When fresh the solution should be clear and odorless; after standing a few days it becomes opalescent, and, what the literature in every instance fails to mention, it acquires a brackish, mawkish odor. In an experience of seventeen cases I have found that if the solution be made from old seeds, or if from fresh seeds and it has stood longer than two weeks, it loses its irritative character and will have no effect whatever. I am disposed to think that an increase of jequirity does not imply an increase of effect, so that the question of preparation becomes purely one of pharmaceutics; that is, as to how much water, whether warm or cold, and if both, how long shall the seeds remain in each? Shall the whole seed be used after being bruised, or only the cortex, cotyledon, or gemmule? The liability to fermentation is so great that it has been proposed to use a germicide in the solution—as salicylic acid, hydrate of chloral, or carbolic acid—a proposition to which, I think, a good chemist would object.

The rationale of treatment is that which obtains in inoculation, viz.: the establishment of an active purulent ophthalmia in place of a chronic, granular ophthalmia, with a view to carrying off the products of the granular conjunctivitis or keratitis: to such the name *jequiritic ophthalmia* could very properly be given. The first recent clinical use of jequirity was made by de Wecker, of Paris, whose report was published in the *Annales d'Oculistique*, for July and August, 1882. A translation of this report appeared in *The Planet*, a new medical gazette of New York, in January, 1883. Moura Brazil published an article on the treatment of acute and chronic granular conjunctivitis with jequirity in the *Annales d'Oculistique* in November, 1882, in which he detailed experiments on rabbits and patients; he found that granulations of the conjunctiva became diminished and sometimes were obliterated. Moyne followed with a paper on artificial purulent ophthalmia produced by *abrus precatorius*, in the *Boll. d'Ocul.*, vol. v., No. 3,

¹ *Abrus precatorius*, Linn

² Read before the Vermont State Medical Society, convened in Rutland, Vt., June 13, 1883.

November, 1882. He was the first experimenter in Italy. The patients were three children, in one of whom the trachoma was entirely removed in twenty days; in the other two the process was milder, but met with a like success. The cornea was not pannous in any of the cases. Simi had an article in the same journal in December, 1882. Jequirity infusion was used on two patients; inflammation and discharge followed, and on the twelfth day the process was complete. On one eye in total, on another in partial staphyloma, there was no change whatever. In the second patient the granulations were decreased, and the patient affirmed improvement in sight. Terrier detailed his use of jequirity before the Soc. de Chirurgie, séance du 13^e Décembre, 1882, in a case of trachoma; purulent conjunctivitis followed, but the granulations did not disappear.

The first published use of jequirity in this country, so far as I can learn, was by Dr. Gruening, whose sketch of two cases may be found in THE MEDICAL RECORD, March 17, 1883. These cases were admitted to the ophthalmic services of the Mount Sinai and German Hospitals of New York, and were perfect successes.

Dr. P. Callan has used the infusion at the New York Eye and Ear Infirmary on three cases without any effect. His cases, so far as I know, have not been published. An exceedingly interesting article from the pen of Mr. Charles Rice, associate editor of *New Remedies*, New York City, appeared in the June (1883) number of that journal, giving the curious history of the seeds, as well as the botanical and pharmaceutical properties of the plant. My own experience of seventeen cases comes next; and, aside from the two cases of Dr. Gruening's and three of Dr. Callan's, I know of no other use of the infusion in ophthalmic practice in this country.

It will be observed that Mr. Rice describes a different preparation of the infusion from that given above, which is the method followed out by Wecker and Gruening. The symptoms formulated by Mr. Rice are more severe than any of my cases developed. All of my patients were treated in the following way: Once a day the solution was applied to both inner lid-surfaces with a camel's-hair brush; the application is painless; two drops were ordered to be instilled into the eye every three hours; and all the patients who would devote the time and thought to the applications, applied compresses throughout the day and a part of the night. In a majority of the cases alteration was noticed within thirty-six hours, and consisted in an acute conjunctivitis followed by discharge, and the deposit of a croupous membrane upon their inner surfaces. The lids were swollen, and the eyes sustained the characteristic symptoms of an acute blennorrhœic conjunctivitis. Within from four to six days the inflammation began to abate, the infiltration of the lids to subside, and the membrane to disappear in shreds. The process of repair was hastened by one daily application of a five-grain solution of nitrate of silver, while a saturated solution of boracic acid was used at frequent intervals to keep the surface as clean as possible. The success in some of the cases was marvellous. The cases first undertaken were dispensary patients, three in number, every one of whom was cured of long-standing pannus. Two private patients, one very young, the other in middle life, were likewise cured—all five within a fortnight; the other twelve succeeded in a less degree, while the conditions of treatment were better fulfilled than obtained with the first five, these twelve being confined to a hospital with a complement of staff physicians and trained nurses.

The following conclusions are formulated from an experience of seventeen cases:

First.—The infusion must be from *fresh* seeds, transparent, odorless, kept from air and light; and must not be used after the development of an odor, or later than a fortnight after its preparation.

Second.—The ophthalmia induced by jequirity is strictly croupous; is limitable in severity by the assiduity and

regularity of the applications, and is not determined by the strength of the infusion.

Third.—The cornea runs no risk of perforating ulcer, and can suffer no more than a transient desquamation of epithelium.

Fourth.—Corneal and in some instances conjunctival granulations from one year to twenty years of existence are successfully removed, with but little pain and little discomfort, in from ten to twenty-one days.

Fifth.—A dense white opacity of the cornea, even of recent standing, remains unaffected by the infusion of jequirity.

It will be observed that in some respects these conclusions differ from those of Wecker, but essentially they are the same.

The following cases are here represented in tabular form:

CASE I.

Patient.	Diagnosis.	Treatment.
Male, aged twenty-eight; occupation, carpenter; treated at Northwestern Dispensary. Improvement in vision twentyfold.	Pannus and conjunctivitis granulosa for ten years. Vision in either eye, finger-counting at four feet.	Infusion of jequirity begun March 4th. Applications painless, but irritating. On third day profuse blennorrhœa, both corneæ covered with a deposit of sarcoous tissue. On fifth day corneæ began to clear; discharge less. On tenth day discharge ceased. On fourteenth day patient was dismissed with V = $\frac{20}{50}$ in each eye.

CASE II.

Woman, aged twenty-five; chambermaid; treated at Northwestern Dispensary. Improvement in right eye thirty-fold; left eye fifteenfold.	General, dense pannus for twelve years. Inversion of four lids, due to fibrous scars on their inner surfaces. Stubby and vicious growth of lashes; bands of symblepharon of both eyeballs. Upper lids had been operated on with benefit for entropion. V = finger-counting at two and four feet.	Infusion of jequirity begun March 3d. Applications painless, but during treatment eyes became painful. On second day free discharge, increase of pannus; later patient was led to the dispensary. On tenth day cornea clear. V = $\frac{20}{50}$ with either eye.
---	--	---

CASE III.

Girl, aged eleven; treated at Northwestern Dispensary. Vision in each eye quadrupled.	Partial thin pannus; cornea steamy, not fleshy; trachoma like frog's spawn on all four conjunctival surfaces.	Infusion of jequirity begun March 28th. Little blennorrhœa and little pain; infusion continued twenty days. Cystic bodies of trachoma (?) removed from all the conjunctival surfaces by the infusion.
---	---	---

CASE IV.

Lad, aged eighteen; occupation, apprentice to a decorative painter; private patient. Vision in each eye doubled.	Superior pannus of both eyes for more than ten years; trachoma of all the lids. Right eye, V = $\frac{20}{100}$; left eye, V = $\frac{20}{100}$.	Infusion of jequirity begun April 1st. Mucous discharge at the end of second day. Lachrymation, spasm, and photophobia considerable. On tenth day right eye had V = $\frac{20}{40}$, left eye had V = $\frac{20}{50}$.
--	--	--

CASE V.

Female, aged forty-seven; had always lived at home; since widowhood a housekeeper; private patient. Improvement in V = eightfold.	Interior pannus of right eye for a number of years, extending up to the horizontal diameter of the cornea. V = finger-counting at eight feet.	Infusion of jequirity begun May 23d. On the third day the cornea was covered with new vessels; blennorrhœa profuse; strips of muco-purulent discharge; no pain; no smarting; lids infiltrated and shiny. On nineteenth day V = $\frac{20}{50}$.
---	---	--

CASE VI.

Male, aged twenty-three; shoveler of sand; treated at Charity Hospital. Improvement in V = right eye, doubled; left eye, none.	Diffuse, dense pannus for five months; trachoma for seventeen years. Right eye, V = $\frac{1}{50}$; left eye, V = $\frac{1}{50}$.	Infusion of jequirity begun May 20th. Reaction slight; some discharge on second day; continued for eight days. On twentieth day, for right eye, V = $\frac{1}{50}$; for left eye, V = $\frac{1}{50}$.
--	---	---

CASE VII.

Male, aged forty; laborer; treated at Charity Hospital. Improvement in V, doubled.	Dense, fibrous pannus for thirty years. Right eye, V = $\frac{1}{100}$.	Infusion of jequirity begun May 20th; reaction slight. On twentieth day V = $\frac{1}{40}$.
--	--	--

CASE VIII.

Lad of seventeen years; worker in a plaster-mill; treated at Charity Hospital. Improvement in V, right eye, none; left eye, threefold.	Maculæ of both corneæ, with recurrent moderate pannus for five years. Right eye, V = $\frac{20}{100}$; left eye, V = $\frac{10}{100}$.	Infusion of jequirity begun May 20th. On second day slight discharge; on third to eighth day increase of discharge. On twentieth day, for right eye, V = $\frac{20}{50}$; for left eye, V = $\frac{10}{50}$.
--	--	--

CASE IX.

Patient.

Male, aged twenty-eight; occupation, machine-tender; treated at Charity Hospital. Improvement in V = double in each eye.

Diagnosis.

Slight, diffuse pannus; and superficial keratitis for nineteen months. Right eye, V = $\frac{20}{80}$; left eye, V = $\frac{20}{120}$.

Treatment.

Infusion of jequirity begun May 20th; reaction slight. On twentieth day, for right eye, V = $\frac{20}{30}$; for left eye, V = $\frac{20}{60}$.

CASE X.

Lad of twelve years; was at school at the Catholic Protectory for eighteen months; treated at Charity Hospital. Improvement in V; right eye none; left eye quadrupled.

Dense pannus crassus of both eyes; profuse discharge; blepharospasm, and photophobia; duration, eighteen months. Right eye, V = inability to count fingers at six inches; left eye, V = $\frac{1}{60}$.

Infusion of jequirity begun May 20th; reaction slight; some conjunctival chemosis and infiltration of lower lids. On twentieth day, for right eye, V = the same; for left eye, V = $\frac{1}{60}$.

CASE XI.

Male, aged fifty; laborer; treated at Charity Hospital. Improvement in V = double for each eye.

A recurrent thin sarcomous pannus for eight years in both eyes. Right eye, V = $\frac{20}{120}$; left eye V = $\frac{20}{80}$.

Infusion of jequirity begun May 20th. On twentieth day, for right eye, V = $\frac{20}{80}$; for left eye, V = $\frac{20}{40}$.

CASE XII.

Male, aged twenty-two; stoker; treated at Charity Hospital. Improvement in V = double for right eye; none for left eye.

A dense, inveterate pannus of each whole cornea for eight years. Right eye, V = $\frac{5}{200}$; left eye, V = $\frac{20}{200}$.

Infusion of jequirity begun May 20th. On twentieth day, for right eye, V = $\frac{10}{200}$; for left eye, V = $\frac{20}{200}$.

CASE XIII.

Male, aged thirty-six; longshoreman; treated at Charity Hospital. Improvement in V, for right eye = double; left eye = treble.

A variable pannus crassus for eighteen years; very dense on entering the hospital. Right eye, V = $\frac{1}{60}$; left eye, V = $\frac{1}{80}$.

Infusion of jequirity begun May 20th. On twentieth day, for right eye, V = $\frac{2}{60}$; for left eye, V = $\frac{3}{60}$.

CASE XIV.

Female, aged thirty-five; domestic; treated at Charity Hospital. Improvement moderate.

Right eye: A variable pannus crassus in superior portion of cornea; dense leukoma of the inferior portion of cornea, V = perception of moving objects. Left eye: Leukoma corneæ, phthisis bulbi; total blindness.

Infusion of jequirity begun May 20th; Reaction slight. On twentieth day, for right eye, V = finger-counting at two feet; leukoma untouched; left eye unaffected by the infusion.

CASE XV.

Female of thirty years; scullery-maid; treated at Charity Hospital. Improvement of V = tenfold in each eye.

Pannus of both corneæ; granular conjunctivitis of four lids for several years. Right eye, V = $\frac{2}{200}$; left eye, V = $\frac{10}{200}$.

Infusion of jequirity begun May 24th. Reaction severe, beginning on third day. Blennorrhœa, swollen lids, but no pain. On fourteenth, for right eye, V = $\frac{20}{50}$; for left eye, V = $\frac{20}{40}$.

CASE XVI.

Female, aged twenty-two; prostitute; treated at Charity Hospital. Improvement of V = fourfold.

Pannus of upper cornea of left eye for five years. Syphilitic cachexia; patient anæmic and scarred; looked old. V = $\frac{20}{200}$.

Infusion of jequirity begun May 20th. Reaction slight. Patient not obliged, except for treatment, to go to bed. On twentieth day, V = $\frac{20}{50}$.

CASE XVII.

Male, aged twenty-five; laborer; treated at Charity Hospital. Improvement in V, right eye = eightfold; left eye = fourfold.

Dense pannus of both upper corneæ for many years; patient syphilitic, though had never had iritis. Right eye, V = $\frac{10}{200}$; left eye, V = $\frac{5}{200}$.

Infusion of jequirity begun May 20th. Reaction not severe; began on fourth day, and continued two weeks. On twentieth day, for right eye, V = $\frac{20}{50}$; for left eye, V = $\frac{20}{200}$.

I am under obligations to Dr. Amory Chapin for assistance in the care of the cases treated at the North-western Dispensary; also to Drs. Battle and Leipziger, House-Surgeons at Charity Hospital.

53 WEST FIFTIETH STREET, NEW YORK.

THE ARTIFICIAL CULTIVATION OF VACCINE.—A prize of \$500 is offered by the Company of Grocers, London, to any one who will describe "a method by which the vaccine contagium may be cultivated apart from the animal body in some medium or media not otherwise zymotic—the method to be such that the contagium may by means of it be multiplied to an indefinite extent in successive generations, and that the product after any number of such generations shall (so far as can within the time be tested) prove itself of identical potency with standard vaccine lymph." Competitors must send in their treatises on or before December 31, 1886, and the award will be made not later than May, 1887.

THE INABILITY TO DISCRIMINATE BETWEEN RIGHT AND WRONG DISGUISED BY AUTOMATISM.

ILLUSTRATED BY THE DISASTERS TO THE BRAIN, TROPHIC AND FUNCTIONAL, ARISING FROM CHRONIC ALCOHOLISM.

By T. L. WRIGHT, M.D.,

BELLEFONTAINE, O.

A RECENT experience with respect to a trial for murder in one of our large cities has impressed upon my attention the importance of a clear understanding of the full significance of the questions so often propounded by lawyers when applied to criminals: "Could the prisoner, in your opinion, discriminate between right and wrong? Did he know, when he committed the act, that he was doing wrong?" The importance of a perfect familiarity with all the terms in these questions, as applied to ascertained facts in criminal cases, is the more apparent when it is remembered that they contain what the courts in England and America insist shall be considered as the real and only test of legal responsibility—the power of discriminating between right and wrong.

In order to prepare the *expert* for the questions indicated, it is usual to furnish him with hypothetical cases, wherein one side will claim a certain regular chain of sequences in the conduct of the accused, all pointing directly to the crime. The answer to the question in such an hypothesis, most likely, is that the prisoner probably did know how to distinguish right from wrong. The other side, with equal ingenuity, will furnish an hypothetical case wherein there are supposed to appear certain breaks, and unreasonable intervals, and inconsistencies, in the same chain of sequences. The same witness will decide that, in such contingencies, the prisoner did *not* know how to discriminate between right and wrong—leaving the case at last just where it was when the expert was called in to testify.

I hope to indicate that a certain regular series of sequences in approaching a criminal act, and made too in the interest of such act of criminality, is not of itself and *necessarily* proof positive that the criminal has sufficient mind to discriminate between right and wrong. Nay, I will endeavor to show that an unusually pertinacious and cunning approach to an act of criminality may even point to the presence of brain disease, which, in the form of some delusion dominating motive and will, proves by its unyielding obstinacy the absence of reason and the inefficiency of evidence, and may thus presuppose a mental defect which is incapable of discriminating between right and wrong.

I hope to make it appear that the knowledge of right, abstractly or automatically and in cold reason only—and the knowledge of wrong abstractly and by mere habit or rote—may be present, and yet the power of discriminating between the two, the power of using the reason and sensibilities in a comparison or analysis of the elements of right as relates to the elements of wrong, may be wholly absent, wholly destroyed. So that it is possible to have an abstract idea of right without feeling it, and an abstract idea of wrong without feeling it; and there may exist an utter incapacity to enter into the mental process of discriminating between the two so as to apply the results of such a discrimination to determining the character of conduct.

In illustrating these propositions, which I prefer thus to toreshadow rather than gradually approximate unto, I will consider some of the effects of alcohol upon the nervous system. I will in the first place, and in some detail, speak of alcohol as a destroying element—wrecking in many instances the integrity of the nerve-centres and of the nerve-tissue otherwise. I will then proceed to consider briefly a more common effect of alcohol, namely, its power of inhibiting nervous function; where the actual mental phenomena—those of paralysis of *function*—must appear very similar to the mental phenomena

associated with deterioration and wreckage of nerve structure.

Dr. Stearns, of Connecticut, says truly that many of the insane are rendered so through grief, business disasters, and other analogous causes. Yet of the whole number of persons suffering from grief and financial reverses, very few become insane. There must pre-exist some neurotic proclivity to the final mischief. So in chronic alcoholism there must also be a similar predisposition to insure the full effect of alcohol upon the tissues of the brain.

It is now the generally received opinion that about *seventy-five* per cent. of the cases of paralytic dementia have a history of alcoholism. Dr. Crothers claims that the percentage is as high as *eighty-nine*. Therefore, to fully appreciate the power of alcohol in wrecking the brain and thus depraving its functions, it is only necessary to observe closely the morbid appearances and changes which are most commonly observed in those who die of paralytic dementia.

"The nature of the most obvious initial change in the brains of the paralytic insane is a hyperplasia of the connective tissue." Certain minute changes observed in the cerebral substance of one who had suffered from this form of disease were owing, according to Dr. Maudsley, to an increase of connective tissue.

In regard to the particular kind of connective structure which is formed through the influence of alcohol, it will be proper to make one or two remarks. Alcohol is recognized as an element more prone than any other to excite the proliferation of the fibrous tissue, not only in the brain but throughout the entire system. Few structures, Dr. Bartholow remarks ("Practice of Medicine," p. 844), "escape the trophic influence of alcohol when it is habitually introduced within the body." The kidneys, the stomach, and the liver, all exhibit an hypertrophy of the connective tissue; "and the neuralgia of the brain also undergoes hyperplasia."

The peculiar nature of the fibroid adventitious structure produced under the influence of alcohol is strikingly exhibited in its subsequent changes. In the kidneys, for example, the alcoholic influence induces interstitial hypertrophy; but finally the hypertrophied tissue *contracts*, just as ordinary scars following burns or wounds contract. This contraction of the hypertrophied tissue produces interstitial nephritis. In the liver this contraction of fibrous tissue, confining and squeezing the true gland-structure among its meshes, produces hepatic sclerosis or hob-nail liver. In the brain a similar contraction produces a variety of disturbances in the condition of the capillary circulation and the nerve-fibres and nerve-cells. "As a consequence of the exuberant increase of the hypertrophied tissue, the nerve-element, as well as the delicate capillaries, are injured or destroyed," says Maudsley.

Of course, such a serious interference with the normal condition of the true nerve-cells implies a corresponding decay and deflection of mental function. It is easy to conceive of the impossibility of mental activity in healthy relationship with natural surroundings when the structures upon which such activity relies for projection—when the nerve-cells—are obstructed in function by the mechanical encroachment of an aggressive foreign substance.

But the injury done to the nerve-cells does not depend exclusively upon the pressure occasioned by hypertrophy of neighboring structure. The final *contraction* of the intrusive connective tissue, by a process of strangulation of the smaller blood-vessels, induces a failure in the proper nutrition of the nerve-element. From this defect in nutrition there often ensues various forms of cell-degeneration. Nerve-cells, for example, may undergo fatty degeneration. Becoming unfitted for physiological action, they may be absorbed, and in their place "fine elastic fibres contract, get closer and closer together, and remain as the constituent tissue of a cicatrix, which

sometimes causes considerable deformity. Whole sections of nerve-substance have been replaced by a relatively small quantity of an unyielding, compact, dry tissue."

The same authority says, in another place: "As the process of hyperplasia goes on, the circulation is shut off, and the brain becomes anæmic. Pigmentary degeneration of the ganglionic cells of the brain is observed in the various forms of paralytic dementia, as also are calcareous degeneration of the same class of cells. . . . In connection with the hypertrophied tissue are amyloid and colloid corpuscles, calcareous and fatty granules, all being products of retrograde metamorphosis" (Maudsley: "Pathology of Mind," pp. 511-512).

In the same direction, Professor Loggia, of Palermo, Italy, says: "When we bring to our aid the microscope, we begin to see and to understand the intimate fibro-cellular and interstitial alterations. It is by this means we succeed in determining the vascular and perivascular lesions of the cerebral substance, the colloid and cistoid degenerations, as well as the lesions of the nerve-element—cells, tubes, and neuroglia—which have, according to the most accurate investigations, undergone great transformations in this disease."¹

But there is still to be considered another important nerve-complication which is also brought about by the toxic power of alcohol—a complication having a very intimate relationship with the moral nature of man, and, of course, with the solution of the problems of this essay in particular.

Besides the cells and centres ministering to sensation, ideation, and motion, and besides the various avenues to and from these centres, there exists in the brain a large and important class of nerve-fibres known as *fibres of association*. To save time and space, I will here adopt the language of some authorities as found in their works on the subject.

Dr. Spitzka speaks as follows: "Many years ago attention was called to the presumptive physiological *role* of certain arched fibres which are known to unite adjoining as well as distant cortical areas with each other. . . . I should, if asked to point to the chief factor on which the higher powers of the human brain depend, lay less stress upon the cortical development as such than on the immense preponderance of the white substance due to the massive associating tracts. Both projecting and associating fibre masses increase in nearly a geometrical progression as we pass from the lower animals to man; but the ratio of progression of the associating fibre masses exceeds that of the projecting tracts. There are certain convolutions which are almost exclusively connected with *fibre arcuate*—that is, with associating tracts—and which enjoy but little direct connection with the bodily periphery. Such cortical areas and their subsidiary associating tracts, bound into the higher unity of the entire hemisphere, constitute the substratum of the metaphysician's *ego*. A disturbance of the intricate relations which are involved in the material basis of the *ego* must be accompanied by a disturbance of the *ego*, or may even render an *ego* an impossibility."

On this subject Dr. Maudsley remarks: "The habitual co-ordination of thoughts and feelings is the basis of consciousness and personal identity. When co-ordination of function in the brain is overthrown, the consciousness of personal identity and responsibility are also destroyed."

Pertinent to the same subject, and also showing a further step in advance in the discussion of our main topic, are the words of Seppilli:² "We must remember that cerebral activity is manifested under two distinct aspects—that of the *conscious* and of the *inconscious*. The conscious activity, or *consciousness*, is constituted of knowledge possessed by the *ego* of its own acts—that which happens within itself, which happens in its relations with the external world. On the contrary, in the unconscious

¹ Alienist and Neurologist, July, 1882, p. 343.

² Ibid, April, 1882, p. 169. Translated by Workman.

activity of the brain, denominated also automatism, all those actions enter in which the *ego* takes no part nor is aware of any; but these are combined and directed so as to *resemble* those which the *ego* perceives, wills, and directs."¹

It is therefore evident that the perfectly harmonious activity, or *consent*, of all the healthy nervous attributes and capacities is the one essential requisite to the display of sound mental function; and as such attributes and capacities are so held in activity through the integrity of the nerves of association, any disturbance or obstruction in the exercise of the functions of those nerves must give rise to serious defects in mental operation. When the interchange of nerve-influence between the various centres concerned in thought is free and unembarrassed, there is present in the mind a vivid sense of personal importance and individuality. The feelings of rights, duties, cares, and responsibilities are active, and they control all the serious avocations of life. This ever-present sense of *responsibility*, while it exacts duties, also confers power and dignity to character, and implies the freedom of the will. The sense of responsibility demands untrammelled freedom of conduct, assumes the weight of accountability, and challenges retribution. There is in the mind an acute sense of its ability to discriminate between right and wrong.

But in chronic alcoholism the free interchange and equilibrium of nervous association does not obtain. It is overcome by the intrusion of hypertrophied interstitial tissue upon the nerves of Meynert. And especially are these nerves of association injured, both in office and structure, by the final contraction of the connective tissue, which, by strangulation, annihilates their function.

Very important considerations of medico-legal interest are interwoven with the tendency of alcohol to impair brain tissue. It is easy to conceive of the unstable will, the impaired will, the imbecile will, when the *consciousness of personality* is weakened and the feeling of responsibility is lost in consequence of injury to the fibres of association. It is also easy to conceive that the power of discriminating between the qualities of right and wrong must be weakened when consciousness is defective. Unless the feeling of personal identity is clear and on the alert, it is impossible to apply personality with distinctness to conduct; impossible to perceive the relations of personality—the relations of the *ego*—to either things or acts; impossible to bring *self* into normal relationship with exact ideas of right and wrong.

It is conceded by all whose authority is of any weight, that one of the earliest symptoms pointing to the progressive paralysis of the insane is a marked change in the disposition. There is a change in the moral nature; not a change indicative of true vice, and exhibiting a reckless disregard of the principles of morality, but a change indicative of an inability to comprehend those principles, and founded, indeed, upon physical damage to the nerves and centres of association—those nerves and centres upon which the sense of morality is based, and through which the moral nature must find utterance.

There was a person within my knowledge who had been a steady drinker. He was honest and was a hard laborer. He suddenly began a course of stealing. It was not like ordinary theft. He would deliberately take and carry away with him things notoriously the property of near relatives and neighbors. He made no attempt at explanation. He claimed these articles to be his own, simply because they pleased his fancy. An infant whose associative organs have not been exercised displays the same ignorance of personality as relates to the personality of others. It cries for and claims as its own any shining toy which happens to engage its attention.

The person alluded to finally died in an insane asylum, demented. He could, without doubt, tell very well what

was the abstract idea of right as well as of wrong. They were ideas which had become *habitual or automatic* with him by life-long use. But practically his nervous organs, functioning the moral nature, having been injured, he could not make an active discrimination between right and wrong. All *feeling or sense* of right and wrong was destroyed through the ravages of alcohol. He was incapacitated, by trophic changes in brain-tissue, from bringing the *conscious ego* into relationship with the moral principles of right and wrong. And this is the difference between the automatic or abstract knowledge of right and wrong, which is to some extent always present, and the *conscious and responsible capacity to discriminate* between the two principles. In the infant, the fibres of association had never yet been brought into play. In the paralytic dement, they had suffered destruction.

But in the insane criminal, the fact often stares the inquirer in the face that the conduct of the accused is consistent throughout with the theory of depravity; that all the steps in the crime were those evincing rational design. This is, indeed, a serious point of consideration. For it not infrequently happens that atrocious criminals, exhibiting the attributes of fine reason and wicked pertinacity, soon after show such indications of insanity as to leave no doubt of their entire irresponsibility.

Certain considerations carefully noted may throw some light upon these undoubted facts.

Habits of thought are acquired slowly and painfully. It is not necessary to advert at length to the difference between man and the lower animals. The former acquires by long and laborious experiment a habit of mental activity fitted for his exalted sphere; while the latter are born with instincts sufficient for their lot in life. The tedious repetition of sensations, perceptions, conceptions, and the motor activities becomes at last a habit which it is impossible to dispense with. Mental and even motor life becomes in time mere repetitions of certain long-enacted powers which are applied to the usual phenomena of living.

The power of walking erect was acquired with much consideration, balancing of the body, and mental calculation. But at length the acts of walking, running, and jumping become by use strictly automatic, requiring no nice calculation, no exercise of the judgment or will in their performance. The undoubted insane walk and run well. Yet no one would claim that because an insane man can perform the act of walking well, an act in its abstract nature requiring judgment and nice calculation, he is therefore not insane, but is in possession of fine powers of judgment and discrimination. There is, therefore, such a thing as automatism, which may mislead the convictions as to the actual present mental capacity of a person of questioned sanity.

There are many other courses of nervous action of a more strictly mental or moral nature which may become automatic, as well as a merely motor capacity. The mature mind, like a bird of prey seeking its food, often comes to intellectual conclusions with wonderful directness and speed, and that, too, from the most remote and unexpected quarters. It is said that when the quarry falls in some deep glen, amid tremendous cliffs and mountain peaks, instantly the eagles flock from remote and hidden places and gather there. This has been ascribed to a mysterious form of impenetrable instinct. The fact is that birds of prey are of grand vision, and they are always upon the watch. The moment that a victim sinks, the watchful sentinel nearest by starts into life, and with rapid wing rises into the air; this movement is at once seen by others farther away, and they too fly aloft and follow the course of the first. And thus, in a few moments, the intelligence goes far and wide—like that from the smoke and torch upon the hills of the Norsemen when an enemy appears.

So the human mind acts. What was once slow and anxious training, what was once pursued in regular steps and over difficulties, becomes by practice instinctive and

¹ "The brain must always remain the essential organ of the manifestations of the *ego* and the *me*—the moderator and the supreme arbiter of the acts of life."—Loggia.

automatic. The alphabetical order of reasoning no longer obtains. Small things are taken for granted. An immense number of positions are habitually assumed; and in ordinary life the mental processes, like eagle-flights, are grand movements from point to point, from headland to headland of thought, not lingering to go through the tedious routine of detailed mental activity.

And thus men not only sane, but men insane, live, and think, and reason, automatically, in common circumstances. It is when some morbid delusion or hallucination intrudes that very considerable exceptions are observed. When we reflect that in the ordinary life of the insane the delusion is not always uppermost in the mind, we must perceive that, in so far as every-day business is concerned, there will usually appear the automatic phenomena and conduct of men in general. When the delusion of insanity takes precedence, there must of necessity be an absence of even automatic regularity in mental activity. So long, however, as the delusion does not intrude, it may be impossible to determine from the conduct of even an insane person that he cannot discriminate between right and wrong; for automatism calls for no active or real process of discrimination. The mind is acting in the groove of habit.

All rational thought, even automatic, is primarily founded upon evidence and reason; and while it may therefore be modified and changed by reason or evidence, a *delusion* founded upon disease cannot be modified or changed except through changes in the disease itself. Of course, changes in a morbid process in the brain are beyond the competency of reason or evidence or will.

The truly alcoholic mind, therefore, is powerless to discriminate between the properties of right and wrong, because it finds itself to be the victim of unusual and untried circumstances, which it can neither define nor correct by the appliances of evidence and reason. It is needless to point out the fact that where evidence and reason cannot come *discrimination* is impossible.

Many truly insane criminals are adjudged sane and responsible because their automatic and common life resembles the similar life of rational minds; while the ignorant cheat and pretender is acquitted because he shams under all circumstances and upon all subjects.

Having considered alcohol as an agent destructive of the integrity of nerve-tissue, and having noted somewhat in detail the effects of such nerve-disintegration upon the mental and moral faculties, we are in a position to determine, with considerable distinctness, what would be the effects of a toxic agent which—by inhibition of nervous function, as by anæsthesia—would render such nerve-function inoperative or defective. For it must be admitted that the suspension of nerve-function from a toxic agency will present the same phenomena as where a similar suspension or destruction originates in any other cause—as, for instance, degeneration of nerve-cells and disruption of nerve-fibres.

Now it is well known that alcohol is an agent which produces anæsthesia in some degree in every instance where it is taken into the system. We have heretofore been discussing alcohol as it affects certain constitutions predisposed to its destructive action upon brain-tissue. Such trophic effects are not the rule. They are comparatively infrequent. But we now come to view a common or universal impression by alcohol upon the brain and nervous system of man; and we infer, from its disastrous effects upon the few who suffer from it in structure, its equally calamitous effects upon those who suffer from it in function.

We will not be specific upon the various properties of alcohol as a disorganizer of the sensibilities. But the fact may be stated that alcohol always depraves or destroys sensation. This may become apparent in the production of true anæsthesia or insensibility to ordinary sensation. Alcohol may also, by its toxic qualities, induce morbid, unnatural, and misleading sensations,

and it may cause sensations to become localized in certain parts of the organism and absent in other parts.

The same confusion in the relations of sensation to perception which exists when the sensibilities are destroyed by deterioration of nerve-structure, exists also when the sensibilities are functionally impaired or destroyed. In either contingency there can be no accurate or reliable perceptions induced. Of course there can be no association of clear and normal ideation, and no certain knowledge or consciousness respecting the actual being and relations of *the self—the ego*. In addition, if the obtunding of the sensibilities continues for a long time through habitual drunkenness, the abnormal state of the sensitive powers becomes constitutional and hereditary, upon the principle of the *structuralization of function*, with its opposite when circumstances are favorable.

But it is time to stop—to turn our eyes from the still opening vistas of our subject. It is enough to add that the anæsthetic state partakes largely of the nature of the magnetic condition, wherein personality is divorced from normal consciousness and wherein man *non est animi compos*.

CASE OF SUCCESSFUL OPERATION FOR THE PERMANENT CURE OF RUPTURE.¹

By ROBERT W. JOHNSON, M.D.,

BALTIMORE, MD.

THE frequency of hernia and the dangerous position of those who are so unfortunate as to own one have made investigation and experiment into the permanent cure of this deformity one of the most prolific themes in surgery.

Probably, if we leave out the excellent and popular truss which girds up the loins of so many of our fellow-citizens, in no department of the profession can we find more labor lost if measured by actual results.

The various means adopted in inguinal hernia, and the various engines, if I may use the term for some of the more cumbersome apparatus, have so far met the approbation of that partial jury alone, the inventor, but have been pronounced by the sterner court of the public: "Tried in the balance and found wanting."

The more prominent methods of invagination, as Gerdy's, Signorini's, Wutzer's, Wood's of London, Wood's of Cincinnati, Dowel's, Chisolm's; Dzondi's transplantation, as practised in a single instance by Jamison of Baltimore; local irritation with compression by Belmas, Pancoast, Velpeau, Armsby, and Riggs—all have either sunk into a merited oblivion or appear in treatises to be tilted at by the author. Heaton's method of injection seems popular now, and with some right, as numerous successes are reported and but few, if any, deaths.

The corkscrew arrangement of Mr. Spatton, of the North Staffordshire Infirmary, has also met with success in *his* hands. The majority of these operations apply only where there is an inguinal canal; when the hernia is an oblique one, and not when the two abdominal rings are dragged into immediate juxtaposition.

With the absence of this canal the difficulty of cure increases, for practically we have a door into the abdominal cavity at which the external ring is at best but a drowsy sentinel. Take away the canal and you rob the operator of his field of action.

Mrs. L. S. C—, aged forty-three, married twenty-two years, six of whose twelve children live, first noticed a small tumor in her right groin, thirteen years ago, one month after the birth, a difficult but normal labor, of her fifth child. This from time to time gave her pain, but was not reduced. After her next labor the tumor increased in size to a hen's egg, and was reduced by Dr. Blackman, of Virginia, who applied a truss for the first time, two

¹ Read before the Clinical Society of Baltimore, Md.

years after the appearance of the hernia. This gave her ease and retained the bowel until the summer of 1881, when the strap having broken she failed to have it fixed, and was rewarded for her negligence by the return of her old enemy with reinforcements. Her physician being unable to reduce it, sent for another physician of this city, who reduced it and applied a truss, which failed to retain it. Coming down again, and being apparently irreducible, her doctor called in a surgeon, who reduced it and applied a truss; but, as she expressed it, before he got into his carriage it was out again. I mention these different attempts by different men to show how impossible it was to keep it up with a truss. The case soon after fell into the hands of Dr. Girter, who attended the woman religiously for some time until her frequent demands wore out his patience, and knowing that I was particularly interested in hernia, kindly asked me to see it with him, she having previously had Mr. Willms to see her twice with the hope of fitting a truss. Finding that I was willing to take the case, Dr. Girter handed it over to me in April, 1882, having called my attention to an apparent cyst, which he had frequently tapped with the intention of setting up adhesive inflammation.

I found on examination an entero-epiplocele about the size of a goose-egg, coming out through the conjoined orifice of the external and internal ring, passing to the labium majus. My finger entered through the ring the abdominal cavity, the walls of which were much relaxed from her numerous pregnancies. At the lower end of the tumor could be felt the cyst, and near it an almond-shaped body, which the patient insisted increased in size during her menstruation, a fact I myself could never verify and pressure of which would give the peculiar nauseous pain of pressing an ovary.

There was but little trouble in reducing the rupture and as long as the supine position was maintained it would not reappear, but whenever the calls of family or nature forced her to leave her bed, back would come the gut, and in spite of renewed trials of trusses, in which Mr. Willms' skill was again elicited, the pain of all of them forced her to remove the pressure, which, although she sometimes endured, did not retain the bowel.

Among other trusses I had one shaped like a horse-shoe, so that the permanent contents of the sac, which I considered irreducible, should not be pressed on, but the gut alone retained. All was in vain.

In the hope that time might accustom her either to the use of a truss or the presence of the rupture in the labium, I attended her from April to November, going sometimes as often as twice a day. Finally recognizing the fact that she could not be so hampered and prevented from earning a living or taking care of her children, and confessing that I was heartily sick of these monotonous visits, I suggested operating, pointing out the danger and stating the possible chances of recovery. After consulting with her husband and carefully considering the matter herself, she asked me to operate. There was no inguinal canal, so invagination was impossible. For the same reason Heaton's method of astringents was discarded. The only thing I saw to do was to reduce the gut, cut down, and tie the sac close to the external ring, and to give her every chance I determined on antiseptic precautions.

On November 28th, assisted by Drs. Gerter, Moah, Schaeffer, and Blumer of Utica, N. Y., I operated under ether. For a half hour previous the spray played in the room.

Having reduced the gut, with its characteristic farewell gurgle, I cut down on a grooved director until I reached the sac, which was, as I had expected, thickened from its long sojourn there. Convincing myself that there was no gut in the sack I ligated it near the external ring with cat-gut ligature, passed around with an artery needle. This was a fortunate procedure, for just at that moment the alcohol in the lamp caught, rendering it unfit for use during the rest of the operation.

Cutting out the piece below the ligature I did not open the peritoneal cavity. Having removed the lower part of the sac and checked hemorrhage by torsion I brought the edges of the wound together over a drainage-tube, including in the uppermost suture the stump of the sac and dressed with antiseptic gauze. Opium, gr. j, to put splints on the bowels, which acted spontaneously on the morning of the operation, and quin. sulph., gr. iij., were given. There was some vomiting from the ether, but that was not enough to strain my ligatures of the sac. Diet was principally light and fluid.

Except in the course of the drainage-tube the wound healed by first intention. At no time was there much discharge. Pain was confined to the wound, no tenderness on pressure except in the immediate zone of incision. Opium and quinine were given occasionally. Removed the sutures on the fourth day; drainage-tube a few days later.

At no time did her temperature, taken twice daily, reach 100° F. I did not allow her to get up for nearly a month after the operation, in order that the parts might get accustomed to their new relations without straining the soft inflammatory tissue near the wound. I have removed her corsets, and to prevent any compression of the parts have suggested shoulder-straps for her clothes as far as possible. I have kept a truss on her and will do so to make security doubly sure, though I think the external ring is now pretty well blocked up. I did not find any ovary in the sac, as her history and almond-like body led me to think possible. The ovular body was, I think, thickened omentum or inflammatory deposit of some standing. I am not casuist enough to think the end justifies the means, and I should have been as much ashamed to present my patient here on her legs as a specimen of her on a plate if I thought my operation unjustifiable. She knew its danger—that at best it might be successful and may be unsuccessful. On the other hand, she recognized that her condition in life would not permit her to be bedridden—that palliative means had had a fair trial. She chose the operation with its attendant danger, and asked me, rather than I her, to perform it.

The best test of my opinion of it is that I would do it again under the same circumstances. I consider it probably the most dangerous of the operations for permanent cure. I would prefer Heaton's or another where there is an inguinal canal. Of course the truss, when practicable, while only a palliative, is far superior to any chances of permanent cure by operation. What effect the spray had I cannot say, as it was not complete. Cleanliness I can vouch for as the best ally I had.

AN OBITUARY COMMENT.—It is rare that one observes the peculiar type of mind which permits itself to indulge in witticisms at the expense of the dead. A recent writer in *The Lancet*, however, who possesses this peculiarity, commenting upon the death of Dr. George M. Beard, says, epigrammatically, that he expended most of his attention upon matters which ordinary men did not think worth paying any attention to. Dr. Beard's studies, thus alluded to, covered such subjects as trance or hypnotism in its relations to evidence, and various problems in morbid and what may be termed "border-land" psychology. Dr. Oliver Wendell Holmes, who, some years ago, speculated upon these same things, anticipated the criticisms thus made by the kindly writer over the water. "There is," says Holmes, "just on the verge of the demonstrable facts of physics and physiology, a nebulous border-land which what is called 'common sense' perhaps does wisely not to enter, but which uncommon sense, or the firm apprehension of privileged intelligences, may cautiously explore, and in so doing find itself behind the scenes which make up for the gazing world the show which is called Nature." We do not know that anything could better offset *The Lancet's* ungenerous estimate of the kind of work which occupied, after all, only a fraction of the late Dr. Beard's attention.—*Medico-Legal Journal*.

PROBABLY A CASE OF TUMOR OF THE CEREBELLUM.

By EDWARD SWASEY, M.D.,
LIMERICK, ME.

ALTHOUGH I am unable to verify by post-mortem examination the diagnosis of tumor of the cerebellum in the following case, yet I think its history, symptoms, and the quite sudden death of the patient were so characteristic of a cerebellar lesion that the case is worthy of record.

Mr. B——, farmer. 36 years of age, married, and always in good, robust health until the past winter. His family history is good; a brother, however, died in early manhood of consumption. He denies any venereal taint.

During the past winter he has been conscious of failing health and strength, and thinks he is fifteen or twenty pounds lighter in weight than usual, but attributes this to unusually hard work during the fall months. No definite symptoms appeared, however, until about January 1st, when he began to have occasional attacks of vertigo, or, as he described it, "a rush of blood to the head." It was most noticeable when he would rise from a horizontal or sitting posture; it would last but a moment or two and then pass off. At times during an entire day he would be free from this trouble. This has been gradually increasing in frequency and becoming more pronounced in character, as not infrequently it was followed by some headache, mostly frontal and parietal.

This has not been very severe or troublesome. About four months ago, or two weeks after the foregoing symptoms commenced, stomach trouble began to appear in the form of atonic dyspepsia. There was partial loss of appetite, a coated tongue, foul breath, bowels at times constipated, but before they had always been very regular: generally some distress after eating, followed by eructation of gas, and very frequently the vertigo and severe headache would come on and remain until the stomach was emptied by vomiting. They would then immediately pass off and he would be comfortable.

He had been under the care of two other physicians a greater portion of these four months, who had treated him for dyspepsia, but he had received very little or no relief, and he says the symptoms have been slowly but surely increasing. He has slept well, and has been free from troublesome dreams. Four weeks ago, in addition to all these symptoms, he commenced to stagger in walking. He has had, during the present week, some occipital headache, but it has not been very persistent or severe.

Such was his past history up to May 4, 1883, when I first saw him professionally. His complexion had the appearance of good health, and he believed he would be "all right" if I could cause the stomach and bowels to perform their functions. The tongue was covered with a dirty white coat, except at the edges, which were clean and red; pulse 60, full and regular; examination of the lungs and heart negative. He was up and about the house. I gave him a powder of pepsin, bismuth, cinchonide, and ginger to take after meals; also a mild tonic of wine of iron, nux vomica, and Fowler's solution. I gave a powder of calomel and jalap to take as the state of the bowels should require. I considered it a case of derangement of the digestive track, and gave a favorable prognosis. On the 6th the appetite had improved as well as his digestion and strength; no vomiting, the bowels had moved slightly, but the head-symptoms were not in the least improved. To continue the treatment, and to assist the bowels to a free evacuation by the use of an injection. I directed that he take short rides and walks, and to be out of doors as much as possible.

On the 8th, the condition about the same, but the dizziness, staggering, and headache were certainly increasing; the latter symptom was still more frontal and parietal than occipital. On returning home from a near neighbor's on the day previous, so pronounced were these

symptoms that he would have fallen but for a fence near at hand, and from here he was assisted to his home by a neighbor.

He had tried to ride, but the jolting and jar had affected his head unpleasantly and caused headache. Fearing that these symptoms had a more serious import than I had at first attributed to them, I subjected the patient to a more careful and searching examination.

The urine was normal in quantity, slightly acid reaction, specific gravity 1.020, free from albumen, but the phosphates were quite abundant; no microscopic examination. There had never been any cedema of ankles or under the eyes. The eyes were perfectly normal in appearance, no nystagmus, pupils normal and responded equally to light; vision for near and distant objects normal. There had been occasionally, at times of dizziness, dyspepsia, but it was transitory. There had never been any trouble in the hearing, and the tick of a watch was heard four feet distant, and equally on either side. The tongue was protruded in a straight line, still covered with the dirty white coat. The facial muscles acted normally. No sign of weakness in arm or hand muscles. He was requested to fully extend the arm and carry it well back, then, with closed eyes, to bring forward the hand and touch the tip of his nose with the tip of index finger. This was done accurately with the right hand, with the left there was deviation of half an inch.

There was no anesthesia of face or extremities. The lower extremities were not tested for ataxic movements. The patellar reflex was normal. No pains in any part of the body, save the headache. In rising from a sitting posture he would have fallen backward, but the side of the room, three feet distant, saved him. He was assisted to gain his equilibrium, but when he stood with feet together there was a swaying motion of the body, but no tendency to retropulsion, or to fall in any definite direction. With the eyes closed these movements disappeared, and the body was stationary. He walked almost exactly like a drunken man. With eyes fixed on a distant object he would start forward, feet wide apart, and the body swaying and tottering about. He crossed and recrossed two rooms in this way without assistance. It brought on some headache, and he was glad to sit down. He felt quite comfortable after a short time, however.

I now came to the conclusion that this patient had a very interesting but a very fatal brain lesion, and that it was probably a tumor of the cerebellum. I gave him the iodide of potash in five-grain doses, and the bromide in ten-grain doses, with a liberal amount of water, three times a day; and ordered a blister to nucha. On the 10th, no special change, except that the iodide had deranged the stomach, as there was almost complete anorexia and a foul breath. The bowels were constipated, but would move by the use of powders and injections. The stools were "clay-colored." There was increased headache, and a disposition to remain in bed. To stop the iodide, but give the bromide and continue the stomach powders and the tonic.

On the 12th, while rising from bed to dress in the morning he fell, striking his face against the bed-frame, causing quite a wound on the cheek. There was no loss of consciousness, had never seen spasms or jerking of muscles in any part. He sleeps well.

On the 14th, no special change in his condition; mind perfectly clear. He has more headache, but sleeps well.

He walks now only with the assistance of his wife. I had him walk alone, however, and the same gait described above was present. The expression of the eyes was that of a drunken man while he was walking, but not afterward. There was not the slightest odor of alcohol about him, and his mind was perfectly clear. I had him take a pin between the thumb and fingers of either hand, and then try to touch their heads together, with arms fully extended. In this there was hardly any deviation from a perfect coaptation.

Has had more occipital headache than formerly. I

noticed for the first time to-day some irregularity of the pulse, but there was no definite rhythm noticed. The bowels respond to medicines somewhat better, and the stools are normal in appearance.

I was asked by the patient's mother for my opinion of her son's condition, and I told her that I took a very gloomy view of his prospects; that I was quite positive that he had trouble of the brain, which would before long prove fatal, but I could not tell her how long before fatal symptoms would appear; possibly weeks might intervene, but I thought not, but when they did appear he would probably have still more severe headache, but I thought the mind would remain clear to the very last, and that he would die quite suddenly. I thought there was little to do in way of medication, except to treat symptoms. That afternoon I met my brother, Dr. William B. Swasey, in consultation, and he took a more hopeful view of the case, regarding it as derangement of the digestive organs, and that the vertigo and headache were dependent upon this. He advised the use of lime-water and milk, and to keep the bowels open by use of calomel. During the examination the patient was in bed, and was laughing and joking, and said that his head was perfectly free from pain just then.

On the 16th I saw the patient at 10 A.M., and found him with head and shoulders raised on pillows, the body and face bathed in perspiration, severe occipital headache, and this was increasing. He still could place the tip of finger on the nose quite accurately. The pulse was 58, and irregular; respiration 25, and regular; no sighing. These symptoms commenced about two hours before my arrival. He had slept well during the night. I noticed slight nystagmus for the first time, and the pupils were in constant motion, they were so sensitive to the light. The mind was clear and it remained so to the very last. The occipital headache was excruciating. The speech was unaffected, though he had some difficulty in swallowing, from a thick secretion of the throat apparently. I promised to see him again that day, but warned the family of the near approach of death, and thought he would not live through the day. I ordered the bromide to be given freely, but in stated doses every half hour for the headache, and a blister to nape of neck for the same purpose. An hour after my departure he rapidly became cyanotic and died, free from spasm or convulsions. The wife told me that the heart beat very rapidly just before death.

Unfortunately I could not obtain an examination of the brain, but as a substitute for this I will briefly review some of the recent literature of cerebellar lesions, and the reader must with me be content to draw his own conclusions respecting the lesion in this case.

My friend, Dr. L. Putzel, of New York, in reviewing the literature of this subject in the past five years, makes these statements:¹ "Nothnagel is of the opinion that lesions whose effects are restricted to one cerebellar hemisphere can not be diagnosed, but this view is contrary to that of various other authors, so that the question must still be regarded as sub judice.

"Disturbances of co-ordination (tottering gait) and vertigo are characteristic of cerebellar disease, but these symptoms may also occur in other affections of the central nervous system, and cannot, therefore, be regarded as pathognomonic. The diagnosis must depend upon the combination of positive and negative symptoms.

"Nothnagel believes that the tottering gait and vertigo are always due to an affection of the middle lobe of the cerebellum; he acknowledges, however, that in exceptional instances the middle lobe may be implicated, although these symptoms are not observed."

In a foot-note to Dr. E. C. Seguin's lectures on "Localization of Spinal and Cerebral Diseases,"² I find this additional statement concerning Nothnagel's conclusions:

"In the large majority of cases the upper extremities remain free from incoördination."

My friend, Dr. L. E. Holt, of New York, has recently recorded an interesting case of tumor of the cerebellum, which I will briefly review:³

A girl, four and one-half years of age, had been in declining health for six months previous to December 11, 1883, when she was first seen by Dr. H. She had been listless and indisposed to any exertion, subsequently had some fever every other day. She vomited frequently, had neuralgic pains in forehead and epigastrium, and occasionally pains in the extremities. There was complete anorexia, and the bowels became obstinately constipated. Occasionally pain and rigidity in back of neck. Three months before she was first seen by Dr. H. she began to stagger in walking, which symptom gradually increased until "she walked like one drunk," and was brought to the Dispensary in her mother's arms. More recently severe occipital headache had occurred. At time of examination, she had a heavily furred tongue and fetid breath. The body was balanced awkwardly, rocking to and fro. Reflexes normal, and there was no decided incoördination, no facial or ocular paralysis, pupils normal, no deviation of tongue, mind unaffected. "On December 16th there was a very marked degree of ataxia of both upper and lower extremities." She was as liable to fall in one direction as another; no jerking movements, and closing eyes made no difference in movements. She improved under the use of quinia (for there was a history of chronic malarial poisoning) for one week, then the former symptoms returned with increased severity, and she died suddenly on January 4th. The mind remained clear to the last, there was some thickening of the speech a day or two before death and some trouble in swallowing. Autopsy revealed "a tumor occupying the situation of the inferior vermiform process of the cerebellum, but it was three or four times larger in size than the process, and it had encroached upon the fourth ventricle."

Dr. Holt gives Nothnagel's conclusions, and in addition to those already quoted, I will give the following: The incoördination from lesion of vermiform process is sufficiently characteristic to be distinguished, in most if not all cases, from that of posterior spinal sclerosis. Its peculiarities are a swaying movement of the body in walking, the legs widely separated, the feet raised but slightly, a staggering, a rocking to and fro, and a final falling in any direction. Closing the eyes may or may not increase the difficulty. The spasmodic character of the movements is usually wanting. The group of symptoms so closely simulates those of alcoholic intoxication that one of Nothnagel's patients was several times locked up by the police for drunkenness.

Vertigo is often an early symptom, and may be the first noticed, but it is of no diagnostic importance unless associated with incoördination. The optic is more frequently involved than the other nerves of special sense. Vomiting is wanting in the stationary and degenerative lesions, but is a more common symptom in abscess, hemorrhage, and tumor. In many cases, especially of tumor, we have occipital neuralgia as a prominent symptom.

I might review other interesting cases that I find on record, but space forbids, and they would but tend to strengthen the conclusions to which Nothnagel has arrived.

RAILROAD SURGERY seems likely in time to develop into a specialty of itself. We are told (*Chicago Medical Weekly*) that organizations have been formed by the surgeons of at least three large companies: The Chicago, Rock Island & Pacific, the Pennsylvania Central, and the Wabash, St. Louis & Pacific. The surgeons of the latter company recently held a successful meeting at Fort Wayne.

A CASE OF DISLOCATION OF THE HIP-JOINT IN WHICH THE HEAD OF THE FEMUR LAY IN THE ISCHIO-RECTAL FOSSA.

BY THEODORE R. VARICK, M.D.,

MEDICAL DIRECTOR AND SURGEON TO ST. FRANCIS HOSPITAL, AND SURGEON TO JERSEY CITY CHARITY HOSPITAL, JERSEY CITY, N. J.

CHARLES B—, a German, aged thirty-six, was admitted to St. Francis' Hospital, Jersey City, October 10, 1882, on account of a dislocation of the hip-joint, sustained forty-eight hours prior to admission. The accident occurred from jumping from the deck of an ice-barge, of which he was captain, to the wharf: a distance of eight feet. How he alighted it was impossible to ascertain, either from the patient himself or from his friends who brought him to the hospital. At the time of the accident the boat lay opposite the wharf at Barrytown, N. Y.

Ineffectual and persistent attempts had been made at reduction before his admission. On inspection the thigh was found to be flexed at an obtuse angle with the abdomen and abducted. A marked depression was observed over the seat of the great trochanter and the head of the bone lay in the ischio-rectal fossa, impinging strongly on the rectum.

In the presence of Drs. I. E. Culver, T. J. McLoughlin, B. A. Watson, and W. W. Varick of the medical and surgical staff, and Dr. H. A. Long, assistant surgeon, the patient was fully anesthetized, and reduction effected by firmly fixing the pelvis, and flexing the leg on the thigh, and the thigh on the abdomen; the limb was adducted and rotated toward the mesial line. The effect of these manipulations was to throw the head of the bone into the great ischiatic notch. From this position, by external rotation and abduction, the head of the bone was made to pass into the obturator foramen. The limb was next rotated inward, abducted, and gradually extended, which caused the head of the bone to slip into the acetabulum with an audible snap.

I have been unable to find any record of a case in which the head of the bone lay in this location. The nearest approach to it are the reports of four cases of dislocation into the perineum, as follows: Dr. Amblarce (quoted by Hamilton), in 1821, records a case in which the precise location of the head of the bone is not stated. Professor Pope, in the *St. Louis Medical and Surgical Journal*, July, 1850, mentions a case in which "the head of the bone was both seen and felt below the skin, and raising the raphe of the perineum." Willard Parker, in the *New York Journal of Medicine*, March, 1852, reports a case where the "head of the bone could be both seen and felt projecting beneath the skin of the raphe in the perineum." Dr. E. W. Hadder, in the *British American Journal*, March, 1861, also reports a case in which "the head of the bone was found under the arch of the pubes, the neck resting upon the ascending ramus."

MEDICINE AND POLITICS.—The Chicago medical institutions, judging from the complaints often made, suffer more from politics than those of most other cities. The County Hospital in particular is cursed by political management, says the *Weekly Review*, and indirectly figures in most of the local political campaigns. It is under the control of the Board of County Commissioners, and as a sample of its local importance the writer remembers when one of these commissioners had thirteen of his own or his wife's relatives engaged in some capacity about the buildings. Not within the memory of the oldest inhabitant has the warden of the institution been known to have been selected on account of any peculiar capacity or experience in such a place.

Something similar might be related of this city, where the city's charitable institutions are made to support a crowd of political heelers.

Progress of Medical Science.

A NEW METHOD FOR THE DETECTION OF SUGAR IN THE URINE.—At a recent meeting of the Clinical Society of London, Dr. Oliver gave a demonstration of the method he employs for the detection of sugar in the urine by means of test-papers. The test-papers were charged with the carmine of indigo and carbonate of soda. When one was dropped into an ordinary half-inch test-tube, and as much water poured in as just covered the upper end, and heat applied, a transparent and true blue solution, resembling Fehling's in appearance, was obtained. (A transparent solution could not, at the meeting, be produced from the London water. The characteristic reaction with grape-sugar was, however, unimpaired). If with the paper one drop of diabetic urine had been added, shortly after the first simmer, a beautiful series of color-changes appeared: first violet, then purple, then red, and finally straw-color: while, on the other hand, one drop of non-diabetic urine induced no alteration of color. The colors returned in the inverse order on shaking the tube, which allowed the air to mingle with the liquid. Reheating restored the colors again. Confirmation of the presence of glucose was obtained by dropping in a mercuric chloride paper, while the solution was still quite hot, after the complete development of the indigo reaction. Then there was produced immediately a blackish green precipitate. No such precipitation occurred when a drop of non-saccharine urine was under examination by the indigo test; then the blue solution was merely turned into a transparent green one. This test, as Dr. Oliver pointed out, discovers (a) the normal sugar; (b) the varying proportions of sugar which fill in the gap between the normal amount and that which characterizes diabetes mellitus, as in liver-derangements and vaso-motor disturbances; (c) diabetic proportions. It possesses the following advantages over Fehling's test: 1. It will detect sugar in any proportion in the presence of albumen, peptone, blood, pus, or bile, and as readily as in ordinary diabetic urine. 2. It gives no play of colors with uric acid. 3. It possesses portability, cleanliness, and stability. Moore's, Trommer's, and Boettger's bismuth tests are all inferior in delicacy.—*British Medical Journal*, May 19, 1883.

A NEW PROPERTY OF THE RED BLOOD-CORPUSCLES.—At a meeting of the Italian Medical Association (*Annali Univ. di Med.*) Dr. Fano related his experiments with peptone, and spoke of the rapid cessation of the reaction of peptone in the blood. He demonstrated the transformations of peptone absorbed by the digestive tract or transfused into the blood-current, and how peptone may be transformed and stored up by the morphological elements of the blood. The transformation consists in a process of dehydration, by which the peptones are changed into coagulable albuminoids. The active elements of this transformation are the red corpuscles which, assimilating the peptones that enter into the circulation, increase the specific weight. It is probably to the potash salts which the red corpuscles contain that this dehydration of the peptones is due, by which they are transformed into globulin. For this process to take place, the presence of oxyhemoglobin is an indispensable condition. The stored-up albuminoids serve as a reserve supply of aliment, which is given up to the tissues as required.

THE BLOOD-VESSELS OF THE SPINAL CORD.—Dr. Adamkiewicz (*Centralbl. für die Med. Wiss.*) says that, when the vertebral arteries are injected, the bulk of the injection finds its way to the cerebellum, and only a small portion enters the vessels of the medulla oblongata and of the cervical cord. The vertebro-spinal arteries are distributed to the spinal cord. The branches of these divide and ramify as far as the roots of the fourth and fifth cervical nerves, then anastomose and form one sin-

gle stem. Their branches are the arteria sulci distributed to the fissures, and the arteria radicinae, which spread laterally to the anterior roots. The so-called arteria vertebro-spinales posteriores spring from the vertebral between the dura mater and the cord itself, and take their course between the anterior and posterior roots as far as the fifth cervical nerve, anastomosing with other vessels and their own branches. The arteria penetrantes, so-called by the author, are the largest branches of these, and penetrate the posterior roots. The spinal cord itself is not supplied by branches of the arteria vertebro-spinales: it derives its blood from a considerable number of vessels—spinal arteries so called—branches of the intercostal, lumbar, and sacral, which enter the spinal canal beside the roots of the nerves. Adamkiewicz points out arteries (arteria magnae spinales) running deeply with the anterior nerve-roots. Each root of the brachial plexus has pretty constantly its own arterial twigs. Great variation is observable in the arteria spinales anteriores; each artery gives off an anastomosing branch. The distribution of the arteria spinales posteriores corresponds very closely with that of the anterior. While the anterior form one continued chain of anastomoses in the anterior fissure, there are two such chains on the posterior surface (anastomoses laterales et posticae). The veins on the surface of the spinal cord exceed the arteries in capacity. On the anterior aspect there are three principal venous trunks, of which the largest traverses the anterior fissure, the other two accompany the anterior roots. The blood passes from these to the median, lumbar, and sacral veins. The author notes more especially: 1, the abundant supply of blood-vessels possessed by the spinal cord; 2, the unusual number and extent of anastomoses which the spinal vessels establish. These conditions readily relieve local disturbances of the circulation by affording increased collateral circulation. The same circumstances explain why myelitis occurs most frequently where the anastomoses are most feebly developed, and where an injection penetrates least readily into the middle portion of the dorsal region of the cord.

THE EXTERNAL APPLICATION OF SALICYLATE OF SODA IN ACUTE RHEUMATISM.—Mr. Whiteley, in *The Lancet*, March, 1883, gives short notes on six cases of acute rheumatism, which benefited greatly from the external use of a lotion of salicylate of soda to the affected joints. The strength of the solution varied from 15 gr. to 20 gr. to the ounce. To those joints to which it was applied, relief followed very quickly, while those joints to which it was not applied were not relieved like the others.

FILARIAL HEMATO-CHYLURIA.—Dr. S. Mackenzie records the case of a soldier, a native of Madras, but born of European parents, who, after arriving in England, found that his urine became increased in quantity, turbid, slimy, and by degrees quite milky. A little later he was seized with a sudden violent pain, extending from the left loin to the left testicle, and was admitted into the military hospital, and thence transferred to Dr. Mackenzie's care. The urine averaged one hundred and twenty ounces in daily quantity, its specific gravity was about 1.010, neutral or faintly alkaline, and contained always some albumen, but no sugar. The urea averaged .6 per cent. Ether readily removed the milky color. It deposited blood, triple phosphates, rarely oxalates, bacteria, and embryo filariae sanguinis hominis. The blood, at night contained numerous filariae, the maximum being reached at midnight, but they were absent during the day. By inverting the order of his life, so that he slept by day and was up at night, this condition of things altered too, and the maximum of filariae in the blood was then at noon. After being under observation some time, patient got a chill, had a rigor, followed by signs of pneumonia at the left apex. This was followed by abscesses at the root of the neck and left shoulder-joint, which were opened. From the date of this illness the urine ceased

to be milky, and the filariae disappeared from the blood. The patient ultimately died, with empyema of right side of chest. The kidneys were slightly enlarged, and in early stage of suppurative nephritis. The mucous membrane of the bladder was thickened, covered with mucus, and contained extravasations. The abdominal lymphatics were carefully dissected, and found to be greatly dilated. The thoracic duct was dilated below and obliterated above. The lymphatics of the left kidney were especially dilated, and contained calculi. No trace of the parent worm could be discovered. No communication could be traced between the dilated lymphatics and the urinary passages.—*London Medical Record*, May 15, 1883.

SWALLOWING OF SHOT AND INSUFFLATION IN THE TREATMENT OF ILEUS.—In three cases with well-marked symptoms of invagination of the bowel (*Gazz. Med. Ital. Lomb.*, Feb. 10, 1883). Dr. Pedrini, after other remedies had failed to relieve, made the patient swallow five or six bullets and four pounds of No. 3 shot, at the same time using prolonged and repeated insufflation of air by the rectum. In each case the success of this treatment was complete, relief being quickly obtained, and the patient making a good recovery.

TAPEWORM A CAUSE OF APHASIA.—Dr. Armangué relates (*Journ. de Méd. et de Chir. Prat.*) the case of a woman of sixty who was seized with vertigo, and a few days later lost the memory of words for some days. After the expulsion of a tapeworm there was no return of her nervous troubles. He quotes a case of aphasia in a child cured by the expulsion of numerous tricocephali, published by Daniel Gibson; and a case of aphasia coinciding with tania, published by Siedel. The editor adds a case of reflex hemiplegia and hemianesthesia, with convulsive seizures, in a little girl of twelve, cured by expelling a tania, observed by Langer in Germany.

DECOCTION OF LEMONS IN MALARIAL FEVERS.—Dr. Maglieri (*Gior. di Clinica e Terapia*, March, 1883) has obtained quite as good results with this simple remedy as with quinine. He finds it efficacious in acute and chronic malarial affections. Given four hours before the onset of a fever, it averts the paroxysm. This it did even in cases in which quinine had failed. In malarial cachexia the general health improved, and the liver and spleen were much reduced in size.

CHYLIFORM EFFUSION INTO SEROUS CAVITIES.—A number of cases of this kind have been collected by Perice and Veil (*Journal de Méd. et de Chir. Prat.*). Veil relates a case of ascites, with milky effusion. The fluid contained a large amount of albumen, and, under the microscope, showed numerous fatty granules, and a small proportion of leucocytes. A post mortem examination showed traces of peritonitis, and gummy deposits in the liver. In two other cases the milk-like fluid was not found at each puncture, the fluid being sometimes clear. Veil believes that the origin of the fat is from the transformation of pus, which dies and then becomes emulsified.

IS THERE A CATARRHAL ULCER?—In the *Berliner klinische. Wochenschrift*, February 19 and 26, 1883, Virchow combats the teaching of Niemeyer, that in acute and chronic catarrh, ulceration or superficial erosion of the mucous membrane of the larynx may occur, and that the inflamed mucous membrane is then in a condition analogous to the denuded cutaneous surface after the rupture or puncture of a blister from a blistering plaster. At the same time, Niemeyer describes follicular ulceration. Virchow holds that from the mucous membrane in catarrh there is simply an excessive flow of its normal secretion, as may be seen in the nasal membranes. This secretion, flowing from an unimpaired surface, is the essential feature of catarrh, so much so that the phrase "dry" catarrh is meaningless to the author, a contradic-

tion in terms. Catarrhal ulceration is equally unintelligible to Virchow. A child, he observes, may have an irritating discharge of mucus from the nostril, which may accumulate about the nostril and lip and cause inflammation and ulceration thereof; but the ulceration being on the skin, and not on the mucous surface, cannot be correctly termed catarrhal. The ulceration of the larynx in phthisis is not catarrhal. The pavement epithelium which extends from the lips to the cardia, with the exception of a small spot at the border of the larynx, is not the seat of ulceration. Parts of the mucous tract that are lined with cylinder epithelium are not thus exempt from ulceration, as may be often seen in the intestines after persistent diarrhoea, and in other parts where glandular follicles exist. Virchow recognizes only as catarrhal the secretion flowing from a simple mucous surface, and repudiates the application of this epithet to any secretion from glandular structures.

EXPERIMENTAL MENINGEAL HEMORRHAGE.—M. Bonnot has published some experiments (*London Lancet*, May 12, 1883), on the effects of injecting fluid blood beneath the dura mater in dogs, with a view of reproducing the symptoms of meningeal hemorrhage. Some of the animals were, others were not, under the influence of anæsthetics. The effects did not appear immediately, but a certain period, termed by Bannot the latent period, intervened between the moment of the injection of three to five cubic centimetres of fluid blood and the first signs of impaired function. The second period was the period of painful excitation. Soon afterward tonic convulsions were observed, characterized by convulsive phenomena and respiratory syncope. The respiration was at first accelerated, but soon suddenly ceased. General convulsions of all the muscles then occurred, and a violent attack of opisthotonos was brought on. The heart at first preserved its rhythm, but, if respiration did not recommence, either spontaneously or induced by artificial means, death supervened, evidently from asphyxia; but if the respiratory process is maintained, the animal may recover, after exhibiting for a longer or shorter period the symptoms of coma, the coma being longer in proportion to the amount of blood injected. Thus, with fifteen cubic centimetres of blood injected beneath the dura mater, anæsthesia was complete and the coma was protracted for a long time. During this comatose anæsthesia the respiration was usually irregular, intermittent, and analogous to that form which is known as the Cheyne-Stokes respiration. The period of tonic convulsions was always short; it supervened more readily if the animal was rendered anæsthetic by chloral, and especially if the subdural injections had been made rapidly, so as to produce an immediate change of pressure in the brain. In no case was M. Bonnot able to obtain evidence of paralysis.

ABSORPTION BY THE PERITONEUM.—Maffucci's experiments (*Giornale Internaz. delle Scienze Med.*) were undertaken with the object of determining whether, besides the diaphragm, there are other absorptive points of the abdominal cavity, or whether it is an absorbing surface in all its extension. From experiments on dogs he arrives at the following conclusions: 1. The diaphragm, great omentum, broad ligament, gastro-hepatic and gastro-splenic ligaments, the folds of Douglas, the meso-rectum, and exceptionally the mesentery, are absorptive of corpuscular fluids. 2. Where absorption of these fluids takes place, there is a modification of structure in the peritoneum, in the epithelial lining, as well as in the subjacent tissue; in the diaphragm there are lymphatic lacunæ, in the rest of the peritoneum lymphatic follicles, which, from these experiments, receive their physiological importance, hitherto conjectured only. 3. Corpuscular fluids are taken up by the lumbar and aortic glands, those of the hilum of the liver and spleen, and of the curvature of the stomach. 4. These fluids, absorbed by the diaphragm, are poured as much into the more complex

glands of the mediastinum, as into the system of follicles. 5. Comparing the abdominal cavity, and also the mediastinum, with the general anatomy of the lymphatic system, in the dog, the first as well as the second may be justly considered as a lymphatic gland with the respective follicles.

IS THERE AN ARACHNOID MEMBRANE?—Dr. Tukes is of opinion that a separate arachnoid membrane does not exist, and that the theory of a subarachnoid space should be given up. In place of this he would describe the brain membranes as twofold, the pia mater and dura mater, and two spaces, the subdural and intrapiamatral spaces.

THE SIMPLEST METHOD OF DETECTING TUBERCLE-BACILLI.—Finding the staining methods of Koch, Auerficht, Ehrlich, Balmer and Fräntzel too complicated and slow, Dr. Zenkevitch recommends (*Mediz. Obozr.*, February, 1883) the following plan as simple, quick, and effective. A lump of sputa is crushed and rubbed between two cover-glasses; then the glasses are separated and allowed to dry in the air; after warming over the flame until the material becomes slightly brownish, the preparation is washed in water and put for one or two minutes in the staining-fluid, which is a saturated solution of fuchsin in anilin water (2 c.c. of anilin to 50 c.c. of water). Then the preparation is again washed in water, and placed for one or two minutes in alcohol containing nitric acid (one drop of acid to each 10 c.c. of alcohol). It remains now to once more wash it in water, dry in the air, warm over flame, and mount it in Canada balsam. The author states that this process of preparation makes the bacilli as clearly and brightly visible as Ehrlich's (or any other) method does. According to his description, a free bacillus, as a rule, has a length equal to one-fourth or one-half of the diameter of a red blood-corpuscle, the longest specimens being equal to three-fourths or even to the whole diameter. The longest rods contain from three to five intensely stained round granules (spores). Fuchsin stains also free spores, which are seen either isolated or grouped in colonies. The examination of the colonial spores allows all the stages of development of the microphyte to be traced from the form of granule to that of rod. Like Balmer, Fräntzel, and others, Dr. Zenkevitch found the bacillus only in phthisis. No rods were detected in the sputa of the patients with acute or chronic bronchitis, emphysema, or croupous pneumonia.

MEDICAL ADVERTISING IN THE NORTHWEST.—Dr. A. W. Parsons, of Bramer, Minn., writes: "In your issue of June 9th last I notice an editorial which reflects upon the professional probity of certain surgeons in the Northwest. I feel assured that the large majority of medical men in this portion of the country most heartily endorse your sentiments, but they will assuredly resent any inference that the practice of self-laudation is as common in this section as your notice would assume. It is a lamentable fact that certain practitioners, in all portions of the country, do not hesitate to divulge to the public, through the columns of their local papers, the results of their skill when such results redound to their credit. But I am sure that a careful acquaintance with the medical men of the Northwest would show you that the practice of quackery and self-praise does not exist among them to any greater degree than in other and older localities. Indeed, I feel called upon to state that the majority of physicians whom I have met during a two years' residence in the vicinity of St. Paul and Minneapolis, have impressed me with the belief that the rapid growth and wonderful development of this new country have been no more than commensurate with the advance in medical and surgical science, and the prevalence of professional intelligence, courtesy, and integrity."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

ACONITIA: ITS USES IN NEURALGIA.

ATTENTION has been again called to this valuable alkaloid by the interesting articles of Dr. Laborde in late numbers of the *Journal de Therapeutique*.

Aconitia (which exists in the root of the aconitum napellus in the proportion of about one drachm to twenty-six pounds) has been especially made the subject of study by the late Prof. Gubler, whose monographs on this medicament are of great practical utility. Gubler was one of the first to insist on the importance of this remedy in the treatment of trigeminal neuralgia.

Aconitia is found in commerce under two distinct forms: the amorphous and the crystallized. The latter, which is somewhat stronger and more reliable, is the best known, and is generally prescribed under the name of Duquesnil's aconitia.

Not to dwell on the toxic effects of this powerful alkaloid, which is only safe in very minute doses, we may sum up its therapeutical actions by the observation that it seems to have a special selective influence on the extremities of nerves of sensation, which it paralyzes. This elective affinity is especially manifest in the case of the fifth pair of nerves.

The beneficial effects of this medicament in neuralgia, in general and facial neuralgias in particular, have been attested by a multitude of observers, among whom we may mention Oulmont, Seguin, Franceschini, Merck, and Laborde. Gubler is fond of narrating an incident which occurred in his practice. It concerned a patient on whom Nèlaton had practised resection "of all the branches of the tri-facial" (!). The pains continued to be just as atrocious and just as persistent as ever. The patient, reduced to despair, and ready to commit suicide, was treated by Gubler with aconitia. Seven milligrammes a day of Hottot's aconitia was administered in granules with the most marked relief, and by perseverance in this remedy a complete cure was effected.

Laborde, in the *Journal de Therapeutique* above referred to, publishes reports of six cases of neuralgia, mostly of the fifth pair, in all of which marked benefit was obtained from aconitia; in some the benefit was permanent. In all these cases the medicine was given by mouth. He makes use of the granules of Duquesnil containing one-fourth of a milligramme. One granule is a sufficient commencing dose, and he advises that the dose should not be repeated under four hours. Generally the second granule will give relief, if the first fails to benefit.

A safe and efficient way, which we have often tried, is the following, which is in accordance with the directions laid down by Dujardin-Beaumetz: Duquesnil's aconitia is ordered—the one-fourth of a milligramme granules. Of these the patient is ordered to take one granule every three hours, till eight have been taken during the twenty-four hours. It is seldom that there is occasion to go any farther. Generally the second or third causes complete disappearance of the pain. Given in this way, we do not exceed two milligrammes a day. If this does not relieve it is vain to push the remedy farther. Sometimes after the second or third granule a little tingling of the tongue, and pricking of the skin of the face, with constriction of the mouth are experienced. Patients sometimes complain that their head feels "hoop bound" for a time.

There is no doubt about the superlative excellence of this medicament in all so-called congestive neuralgias, as we have notes of obstinate cases of sciatica which have proved amenable to treatment by aconitia. It is one of the remedies that should be first tried in severe sciatica and lumbago, *a frigore*.

Even in the case of symptomatic facial neuralgias, as well as protopathic, the pain is often alleviated by aconitia, as Laborde has shown.

GREEK OR GERMAN—WHICH?

A COLLEGE graduate, prominent in the profession, said to us recently: "If I could exchange my knowledge of Greek for German, it would be worth everything to me now. It is mortifying to be dependent on others for information as to what is going on in the great medical centres of the old world."

Our friend spoke the sentiments of multitudes who, in their collegiate days, spent in acquiring a knowledge of Greek the time which would have made them proficient in any one of the modern languages. Amid the cares of a busy life they have no leisure now for the German grammar and lexicon.

Charles Francis Adams, Jr., in the annual oration before the Phi Beta Kappa Society at Harvard recently, had the courage to advocate a radical change in the course of studies pursued at that University. It is seldom at college commencements that so much wholesome truth is told. He asserted that the traditional college course does not fit the graduate for the duties of life, but diverts him from them. He appealed, in confirmation of his charge, to the experience of his great-grandfather, his grandfather and his father, also to his own experience, and that of his brothers. John Adams, the second President of the United States, had learned what Greek was taught at Harvard, and at the age of forty-two was appointed ambassador to France. They did not talk Greek in France, and he found himself in an awkward predicament from ignorance of the language. The same was afterward true of John Quincy Adams, and of Charles Francis Adams, and had been true of the orator. He maintained that the study of Greek had been a hindrance and a waste of time to every liberally educated member of the family, and that this experience has been by no means exceptional. The same time devoted to the study of the modern languages would be of more advantage, though the speaker did not object to Latin,

since Latin is the parent of most of the European languages.

As for the vaunted discipline obtained from the study of Greek, it is no more than can be acquired from the study of German; he thought that Plato and the venerated names of Greek literature were greatly overestimated by tradition, and that the study of the Greek grammar was a total waste of time, and that as an intellectual exercise it would be just as beneficial to the student to memorize Kant's "Critic of Pure Reason." In short, Mr. Adams considered the Greek worship as fetich, and would reorganize college education by leaving out Greek and substituting German and French. All certainly that is valuable in those old writers, Plato and Aristotle, etc. (and there is very much that is rubbish), could be obtained through the medium of a translation.

For young men intending to enter the medical profession, it is a pity to waste a year of study and spoil a good pair of eyes over Greek declensions and dialectic variations, and in trying to get the hidden meaning of authors who give no more practical thought than can be obtained from the masterpieces of English literature, while the Continental languages still remain unknown, and the whole broad field of physical science remains unexplored. The radical change which Mr. Adams so eloquently urges must soon come.

BOOKS OR BACKGAMMON.

DESPITE the fact that Wood's Medical Library Series circulates largely in the West, it is said that the benighted physician still lives, in some parts of that vast indefinable region, who speaks of Astley Cooper as the "greatest living surgeon"—whether he votes regularly for Andrew Jackson is not known. Several years ago we met with a practitioner out "West," doing a comfortable business (so he said), whose library consisted of only two books, Hartshorne's "Essentials," and Druitt's "Vade Mecum." He had chosen wisely and well, but his enthusiasm for knowledge was somewhat too moderate. Unfortunately he had a strong predilection for certain games of chance, which, if they demand much time of their votaries, confer little discipline.

We think there are few in the profession who so little feel the responsibilities of the vocation which they have chosen as did our Western confrère, who notwithstanding the fact that he was liberally supplied with self-confidence, must not seldom have found himself insufficiently prepared for the serious duties before him; this we say without any disrespect for the eminent authorities whom he was in the habit of consulting. His case is, perhaps, not widely dissimilar to that of many who buy books and take journals which they never read. Better the "Essentials of Medicine," well studied, than all of Ziemsens, kept simply to ornament the shelves.

The great body of medical men throughout the country are, we feel assured, men who, feeling the gravity of the tasks which they daily undertake, seek all the light they can get. They are diligent students of all the great masters in medicine and surgery. They have no time for whist or for lounging. The more work they have to do the more time they must find to read and meditate. Preparation for their daily duties must be made, if the midnight lamp must be burned. They must diligently

con their medical journals, for they need the experience of others to guide them. Moreover, they must record their own experience, much of which is too valuable to lose. Thus, and thus only can they discharge their obligations to their constituency and to society, by assimilating the best thoughts of the age, and by helping on the car of progress.

MEDICAL EDUCATION THE FUNDAMENTAL FACT IN MEDICAL ETHICS.

At the last meeting of the American Medical Association, Dr. A. L. Gihon, U.S.N., read a paper upon the above title, at the close of which he submitted the resolutions given below. They were promptly rejected by the Association. It seems incredible that temperate and sensible men should fail to acknowledge that Dr. Gihon's views are in the main correct; and that what our profession most needs, and should most work for, is better educational requirements. The resolutions presented are somewhat radical, and their author would doubtless have made more impression if he had suggested, at the beginning, less sweeping reforms.

It may be questioned, also, whether the American Medical Association can carry out any serious medico-political measures, so long as it is an unchartered body with a shifting membership and without legal status.

We print the resolutions, which are at least very suggestive, in full:

Resolved, That the Section in State Medicine urges upon the Association the necessity for at once taking steps to exclude unqualified members from the profession, by refusing fellowship to illiterate, ignorant, and incompetent graduates.

Resolved, That the Association be recommended to authorize the Section in State Medicine to act as a Standing Committee on Medical Education, the several elected members being required to communicate without delay (1) with the several State medical societies and the Legislatures of the States they respectively represent, with the object of creating *State Boards of Medical Examiners*, where such are not already in existence, whose certificate shall be necessary to the issue of a license to practise medicine in that State; and (2) with the authorities of every regularly organized medical college in the State, which has not already taken such action, urging upon them, *First*, the requirement of a *proper preliminary education of matriculants*, to embrace at least a knowledge of English orthography and grammar, the etymology of the more common Greek and Latin derivations and the fundamental rules of arithmetic, to be ascertained by a written examination, preserved for reference; and, *Second*, *greater care in ascertaining the fitness of candidates for a degree*, by making their final examination in part a written one, to be kept on record and accessible for inspection by State Boards of Medical Examiners, Boards of Censors of Medical Societies, or other authorized persons requiring information as to the professional qualifications of graduates.

Resolved, That in the opinion of the American Medical Association, medical colleges should confer upon graduates the degree of *Bachelor in Medicine*, such graduates to be eligible to the degree of *Doctor in Medicine* at the end of three years, after having given satisfactory evidence of their qualification to the Board of Censors of the State Medical Society.

Resolved, That Article II. of the plan of organization of the American Medical Association be amended by this additional proviso :

Provided, That every permanently organized State, County, or District Medical Society entitled to representation in this Association shall be required to appoint a Board of Censors, who shall rigidly scrutinize the literary and professional qualifications of every candidate for membership therein, and hereafter no delegate shall be admitted to a seat in this Association who shall not have received the certificate of such a Board of Censors or of a State or National Board of Medical Examiners.

THE NEW TARIFF ON DRUGS AND CHEMICALS.
ON July 1st the new tariff regulations went into effect. Nearly forty per cent. of the entire number of listed articles comes under the head of drugs and chemicals. Hence the present change will have some effect upon those who make and dispense medicines. Heretofore a duty of 20 per cent. has been charged upon chemicals, and a duty of 40 per cent. upon medicinal preparations. Under the new tariff they are all placed at 20 per cent.

The general effect of this change will be favorable to manufacturers of drugs and chemicals on account of the reduction of the tax upon the articles used in manufacture.

The retention of quinine upon the free list has, says Mr. D. C. Robbins somewhat dolefully, destroyed its manufacture in this country. The United States, he says, consumes 1,600,000 ounces annually, of which one-half is imported, when it should all be made here. Not being manufacturers, but consumers, we can hardly see the force of this logic.

Among the more common articles on which the duty has been lessened, we present the following list.

ARTICLE.	Unit.	RATE.	
		Old.	New.
Glycerine, crude....	Value and lb.	30 per cent.	2 cents.
Phosphorus.....	Value and lb.	20 per cent.	10 cents.
Castor oil.....	Gallon.	\$1.00.	80 cents.
Croton oil.....	Pound.	\$1.00.	50 cents.
Oil, flax seed, linseed, cotton seed.	Gallon.	30 cents.	25 cents.
Mineral waters, artificial, imitation.....	Value and qt.	3 cents plus 25 p. c.	30 per cent.
Boric acid, pure..	Pound.	Free.	5 cents.
Potash, chromate and bichromate.....	Pound.	4 cents.	3 cents.
Copperas.....	Pound.	$\frac{2}{10}$ per cent.	$\frac{2}{10}$ p. c.
Magnesia, medicinal carbonate.....	Pound.	6 per cent.	5 cents.
Soda, caustic.....	Pound.	$1\frac{1}{2}$ per cent.	1 cent.
Zinc, oxide of dry..	Pound.	$1\frac{3}{4}$ cents.	$1\frac{1}{4}$ cents.
Oils, essential, expressed, n. o. p....	Gallon.	20 per cent. to \$1.00.	25 per cent.
Official medicinal preparations.....	Value.	40 per cent.	25 per cent.
Barks, beans, etc., ground or refined.	Value.	20 per cent.	10 per cent.
Chloroform.....	Pound.	\$1.00.	50 cents.
Opium, preparations of, n. o. p.....	Pound.	\$8.00.	\$10.00.

The increased duty on opium refers only to its preparations.

Besides the above, a considerable number of articles have been placed upon the free list.

The results of the new tariff as regards consumers ought to be a slight reduction in the price of many drugs. It will, however, be some time before the public finds any noticeable difference.

News of the Week.

THE BOYLSTON PRIZE, of \$200, for the best essay on "Measles, German Measles, and Allied Diseases," has been awarded to Dr. P. M. Braidwood, of Birkenhead, England.

MEDICAL EDUCATION VS. MEDICAL ETHICS.—The Bellevue Hospital Medical College announces itself as adhering to the old Code, but requires no preliminary examination of its matriculants.

DR. J. H. THOMPSON, of Rome, Italy, is on a short visit to this city.

DR. SPINA, Koch's opponent, has been nominated Professor of General and Experimental Pathology at Prague. This may be considered an endorsement of the value of Spina's work.

PORRO'S OPERATION was performed by Dr. Parrish in Philadelphia recently, upon a dwarf. The patient survived for several days, but finally died.

YELLOW FEVER TRANSMITTED BY DESPATCHES.—It is stated that one of the officials of the Foreign Department at Paris has caught the yellow fever through a despatch sent from Brazil. One of the daily papers wonders if it was a telegraphic despatch.

EXPERIMENTAL INOCULATION WITH SYPHILIS.—It is stated that Dr. Cory, the Director of Animal Vaccination at the Vaccine Establishment, London, England, has inoculated himself with syphilis while making experiments on himself as to whether syphilis can be communicated from one body to another through vaccination. One would have thought that the possibility of transmitting syphilis by means of vaccination was sufficiently well established without any further experiments, and certainly one would have supposed Dr. Cory could have had no doubt of the fact. At all events, if reports as to his sufferings from the inoculated disease are true, he must be thoroughly well convinced of the fact that at least one of the means of getting syphilis into the system is by means of vaccination. It has been officially stated, however, that "the result of transmitting the infection of syphilis was not attained without departing in essential respects from the Board's instructions to public vaccinators and from the recognized practice of all vaccinators."

THE SUMMER SANITARY INSPECTORS have been appointed by the City Board of Health. The total number appointed was fifty, and work was begun on July 9th. We observe a large number of new names upon the list. New brooms sweep clean, and there are some reasons for thinking that some change will not be disadvantageous.

YELLOW FEVER.—Infected vessels have appeared at Galveston, Pensacola, Ship Island, and at date one is on the way to this port from Havana. No cases have yet occurred, however, except on the vessels. A despatch says: There are two vessels at Ship Island in charge of the Surgeon of the Marine Hospital Service, who established himself in the quarters of the late National Board of Health yesterday, and one vessel at Galveston and two at Pensacola are under orders to proceed

thither. There has been undisguised bitterness of feeling between the retiring officers of the National Board and the incoming agents of the Marine Hospital Service, and the latter, when they took charge, found the quarantine station at Ship Island gutted of all conveniences and properties. Even the steam despatch boat, Day Dream, had been sent away, but she has since been discovered tied up to the levee at New Orleans and taken possession of by the Treasury Department. The officers of the National Board have had her up for sale for the past few weeks, but they were unable to obtain a purchaser. Upon the withdrawal of the inspection service of the National Board the Sanitary Council of the Mississippi Valley assumed charge of the same, it being decided at several up-river points that certificates of the Marine Hospital Service would not be recognized.

DR. HOLMES will deliver the address at the opening of the new building of the Harvard Medical School, October 15th.

A MONUMENT TO FABRICIUS is to be erected by the citizens of Acquapendente, Italy.

THE THIRD INTERNATIONAL CONGRESS OF ANTI-VACCINATIONISTS will meet in Berlin this summer. New York sends three delegates.

THE NINTH ANNUAL MEETING OF THE TRI-STATE MEDICAL SOCIETY will be held at Indianapolis, September 18th, 19th, and 20th. Especial efforts to make this meeting a success are being made by its energetic officers.

THE LATE DR. BEVERLY LIVINGSTON.—At a meeting of the Medical Staff of the Northern Dispensary, held July 6, 1883, the following resolutions were adopted:

Whereas, We learn with profound sorrow of the death, at the outset of a promising professional career, of our late associate, Beverly Livingston, M.D.; therefore be it

Resolved, That in the death of Dr. Livingston the medical profession loses a worthy member, the Northern Dispensary an efficient aid, and the members of the staff an associate whose genial qualities and untiring zeal will long be remembered.

Resolved, That our most sincere sympathy be extended to the family of our late associate.

Resolved, That a copy of these resolutions be published in THE MEDICAL RECORD and transmitted to the family.

A. F. PRAY, M.D.,
C. D. HAYWARD, D.D.S.,
R. W. GLASSFORD, M.D.,
Committee.

THE PROGRESS OF THE CHOLERA EPIDEMIC.—The number of deaths from cholera have, up to time of writing, been as follows:

	At Damietta.	At neighboring towns.
July 3d.....	124	43
July 4th.....	111	63
July 5th.....	116	63
July 6th.....	101	52
July 7th.....	98	60
July 8th.....	96	61
July 9th.....	87	9

The number of persons killed by the disease at Damietta (July 11th) now amounts to about twelve hundred, or over one-twenty-fifth of the population. It has been

very malignant, but has so far been confined almost entirely to the natives. The disease is travelling up the Nile, having already reached Shirbin, a small village thirty miles above Damietta, Mansurah, a town twenty miles beyond, Menzalen, and Samanoud, the last a small village only seventy miles below Cairo. It may possibly have reached Cairo by the time this appears. Some cases have been reported at Alexandria. The disease was due in Egypt in 1877, having appeared regularly every twelve years since 1781, spreading always to the west and taking about two years to exhaust itself. In all previous instances the epidemic has developed energy among the oriental races, whence it has spread to Europe. The exodus which has taken place from Egypt is likely to carry the infection to the adjacent towns of Syria, and particularly to Beyrout, whence it may spread to any point on the Mediterranean. A number of vessels from Bombay, carrying pilgrims to Mecca, are expected at Geddah, and it is likely that the epidemic will be brought by them. All the European Governments have established strict quarantine regulations as to vessels coming from Egypt except England. The Sanitary Council of Constantinople, in order to prevent the introduction of cholera, have resolved to ask the Porte to request the Egyptian Government to prohibit refugees from starting for the Turkish coasts, and to inform that Government that if any refugees do arrive at ports belonging to Turkey they will not be allowed to land. Sanitary cordons have been drawn around some of the infected towns.

Reviews and Notices.

MEDICAL ESSAYS, 1842-1882. By OLIVER WENDELL HOLMES. Boston: Houghton, Mifflin & Co. 1883.

THIS volume embraces nine essays, most of which are more or less familiar to our readers. They vary somewhat in merit and interest.

The essays on "Homœopathy and its Kindred Delusions" will always remain the most brilliant and masterly criticism that has ever been made of the development of medical isms. As a contribution to the subject of the value of human testimony also, no one can read it without being instructed. We mistake—there is the world of the pig-headed, of the unteachable Philistine—and besides (we crave pardon) there are the ladies—to these two classes Dr. Holmes's essay is unintelligible; hence our pathies and our patent medicines.

The essay on "The Contagiousness of Puerperal Fever" is of another character, and illustrates the capacity of the author for dealing with scientific questions. The issue for which Dr. Holmes contended with so much earnestness and effect is now a dead one, but dead because all agree with what Holmes laid down in 1843.

The essay entitled "Medical Currents and Counter-currents" is a pungent criticism upon the practice of overdosing, and a philosophical analysis of why we give and when men take medicines. But, although this chapter contains much that is witty and instructive, the subject of therapeutics now-a-days is looked upon from a somewhat different standpoint than it was twenty-five years ago, since which time the physiological school has developed.

Of the remaining essays those on "Bedside Instruction" and "The Young Practitioner" are perhaps the best. They especially illustrate the relations of our author toward medicine.

There is no transcendentalism about Holmes. He

preaches common sense, humanity, and small doses. He pleads for a knowledge of human nature as well as of the human body, for sound observation as well as for study. He has a little feeling of antagonism toward the present tendency to cultivate the medical sciences; a feeling which Trousseau showed when he said: "Good heavens, gentlemen, a little less science, a little more art!" Dr. Holmes is the essayist *par excellence* of the practitioner. We fear that, as regards pure science, he is a bit of a Philistine himself, and it is somewhat interesting to find that our author, who has attacked non-conductive dulness all his life, now shows a trace of it himself in his relations to medical progress. For it is certain that the advancement of medical art is not in the hands of our great and successful practitioners, but with the patient workers who are trying to follow nature into her last hiding places.

BRAIN-REST. By J. LEONARD CORNING, M.D. New York: G. P. Putnam's Sons. 1883.

DR. CORNING has given us a little work which is of considerable interest. It is written with evident care and in a scientific spirit. The author preaches the value of securing brain-rest by regular sleep at proper hours. He describes his own device for carotid compression, and mechanically regulating the cerebral circulation, with all of which our readers are familiar. Dr. Corning's discussion of pathology of "brain-exhaustion," with its cerebral hyperæmias and anæmias, appears to us to be a trifle amateurish. We might say the same regarding some of the theoretical parts. On the whole, however, the book is a very creditable and suggestive contribution to the important subject with which it deals.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF MISSOURI, at its Twenty-fifth Annual Session, held at Hannibal, Mo., May 16, 17, and 18, 1882.

This year's report gives a marked increase in membership since the last meeting. The president's address is devoted mainly to the exposure of quackery and the several classes of "quacks," with which the State is apparently pregnant. Very little in this direction can be accomplished by such means. We would advise an application to the State legislature through a properly appointed committee, as the true means of working out the reform needed. Considerable good work is, however, shown to have been performed during the year, much of which is indeed commendable.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF GEORGIA. Thirty-third Annual Session, held at Atlanta, Ga., April 19, 20, and 21, 1882.

MUCH praise is due to the secretary of the Society, A. Sibley Campbell, M.D., for his untiring efforts in securing the handsome appearance of the volume before us. We have no doubt, from the many very valuable articles of general interest to the practitioner contained in the text, that a sufficiently large number of copies will be disposed of to leave a balance in the treasury. The finances of the society are, we regret to say, in a poor condition, due, however, to the carelessness or unwillingness of members to support its interests by paying their just dues. This cannot be too severely censured. The book is handsomely printed on fine toned paper and elegantly bound in cloth for permanent use.

SIXTY-NINTH ANNUAL REPORT OF THE TRUSTEES OF THE MASSACHUSETTS GENERAL HOSPITAL AND MCLEAN ASYLUM. Boston, 1882.

FROM a comparison with the previous year's work, the report shows a slight increase in the number of patients treated at the Hospital, together with the receipt of several munificent donations, which, from the treasurer's report of the finances, owing to numerous improvements in the way of building, etc., during the year, were not among the least to be desired. At the Insane Asylum a similar increase in patients is noticed, but also a relatively

larger percentage of recoveries than for several years previous. Altogether, both institutions are in fair and prosperous circumstances. Superintendent Cowles is to be commended for the earnestness manifested in his work.

TRANSACTIONS OF THE OHIO STATE MEDICAL SOCIETY.

Thirty-sixth Annual Meeting, held at Columbus, June 14, 15, and 16, 1881.

THIS volume opens with the report of the Transactions of the society, the address of welcome being delivered by Mayor Peters. Following this and comprising the body of the work, are the reports from the several departments of medicine, together with a number of excellent papers on subjects of general importance to the profession, many of which will be read with profit.

FOURTEENTH ANNUAL REPORT OF THE PRESBYTERIAN HOSPITAL IN THE CITY OF NEW YORK, FOR THE YEAR 1882.

THE present report covers a period of nineteen months. The total number of patients received during this time is 1,918; during the past year, 1,202, or nearly double the number treated for the year ending April, 1881. An extraordinary large number of accident cases is also noticed, and owing to the great increase in these directions, the duties of the medical staff have been unusually severe. The superintendent's report is in the highest degree creditable. The finances of the institution are seen to be at an ebb and need replenishing; this should meet with prompt action from the proper quarters.

THE NEW YORK INSTITUTION FOR THE IMPROVED INSTRUCTION OF DEAF MUTES. By D. GREENBERGER, Principal. Reprinted from the *Archives of Otolaryngology*, Vol. XII., No. 1, March, 1883.

THIS pamphlet gives an exhibit of the workings, etc., of the institution, for the benefit of those devoted to this specialty.

ANNUAL REPORT OF THE MANAGERS OF THE WESTERN PENNSYLVANIA HOSPITAL FOR THE INSANE. Dixmont, 1882.

FROM this report we find that there were treated during the past year 768 patients, male and female; showing an increase of 173 over the previous year. There were discharged 267, and 46 died, giving a decrease in the corresponding rate of mortality.

SIXTH ANNUAL REPORT OF THE BOARD OF HEALTH OF THE STATE OF NEW JERSEY, 1882.

THIS extensive and carefully prepared volume leads one to presume that the duties of the board have been unusually onerous during the past year. The mortality, we notice, shows a considerable increase (5,130) over the previous year, due, in a great measure, it is believed, to the exceptionally severe summer and winter. The report, moreover, goes very extensively into the sanitary condition of the State, the sewage, malaria, etc., an excellent exhibit of the duties to be performed, and which, it is hoped, will not be overlooked.

ELEVENTH ANNUAL REPORT OF THE NEW YORK INFANT ASYLUM. January, 1883.

JUDGING from the annual report, the duties of the past year have been remarkably arduous. The management has, however, been admirable, and the exhibit of the Medical Board is in every respect very gratifying. A steady increase in the number of patients is noticed, and the usual assistance and shelter has been rendered to friendless women. The professional labors of Dr. Kate Parker, resident physician at Sixty-first Street, are worthy of the highest commendation. Undoubtedly, however, the greater part of the work of this institution is unwritten and unappreciated by the community at large. Nevertheless, as an object of Christian charity, no one of our hospitals or asylums is more eminently deserving of the widow's mite.

FIFTH ANNUAL REPORT OF THE CONNECTICUT STATE BOARD OF HEALTH, FOR THE FISCAL YEAR ENDING NOVEMBER 30, 1882.

FROM the elaborate volume at hand, an amount of labor and zeal in sanitary affairs is shown that is truly commendable. It is evidently the intention of the board to devote untiring energy in this direction toward improving the sanitary condition of several localities. Some original work may be expected during the current year.

ANNUAL REPORT OF THE DIRECTORS AND MEDICAL BOARD OF ST. MICHAEL'S HOSPITAL. Newark, N. J. January 1, 1883.

BESIDES the large number of cases treated, an important feature of the past year's work is the re-establishment of the eye and ear clinic, and we are glad to say, with satisfactory results.

LECTURES ON MEDICAL NURSING. BY J. WALLACE ANDERSON, M.D. Lecturer on Medicine, Royal Infirmary Medical School, and Physician to the Royal Infirmary Dispensary, Glasgow. Second Edition, pp. 224. New York: Macmillan & Co. 1883.

THE fact that this little work is already in its second edition would seem to be sufficient evidence of its practical usefulness. Besides the immediate care of the sick and attention to the several details of nursing, not only in a general manner, but also in special conditions and diseases, all of which, moreover, is exceedingly well presented, the employment of numerous therapeutic measures, cold in various forms, blisters, injections, leeches, etc.; the examination of the pulse, the urine, the temperature; administration of stimulants, narcotics, etc., and their indications, all receive the most careful consideration. A series of questions also supplement each lecture. In short, every minute detail of the clinical history of medical nursing, and its practical application, is presented in an exceedingly interesting manner: and to those who purpose making this subject a study, the work will prove not only instructive but a highly valued friend. Indeed, we doubt not that many general practitioners will find this book both interesting and suggestive.

THE "VANDYKE BROWN" POEMS. BY MARC COOK. Edited by his wife. Pp. xviii., 225. Boston: Lee & Shepard. New York: Charles T. Dillingham. 1883.

FOR the thoughtful physician who has come to regard his lifework in its broadest sense, as peculiarly a study of humanity, this unpretentious volume will possess a pathetic and more than passing interest. Apart from the portrait of the author which faces the title-page, and which presents that vivacity of intellect and sanguine temperament which so often are painfully combined and intensified by prolonged pulmonary disease, it does not require a great amount of professional acumen to read between the lines of the poems which follow, as plainly and surely as from a temperature-chart, the varied phases of the one-sided struggle for life.

The profession is already well acquainted with the history of the case of Mr. Cook, as embodied in his little treatise on "The Wilderness Cure" (William Wood & Co., New York, 1883), and his well-known article on "Camp Lou," published in *Harper's Magazine* for May, 1881, each of which were evidently written while the author was filled with new hope by the delusive invigoration of rest and the stirring air of the Adirondacks. Little more than a year from that time found him in his grave, another pitiful instance of the sarcasm of fate.

This collection of his stray poems, gathered and placed in permanent form by those who knew and loved him best, should plainly be viewed as an affectionate tribute to his memory, rather than a bid for notoriety. Read with the charity which in the nature of the case it demands, this book cannot fail to be appreciated.

Mr. Cook's chief claims to excellence as a poet are a sprightly and easy versification, and an aptitude, espe-

cially in his serious attempts, of enveloping each poem as a whole in the atmosphere, as it were, of his own peculiar mood; thereby not only fascinating the attention of the reader, but bringing him to that intimate sympathy with the subtler shades of the writer's mind which is so rarely attained. Like all young writers he is crude, and like all young writers he at times shows the influence of older minds upon his style. Thus, one may easily find instances when he reminds us forcibly of Holmes, Whittier, Bret Harte, and Aldrich. In our opinion, his style, notwithstanding an obvious individuality, closely resembles that of Aldrich. There are several of Cook's poems, notably "L'Envoi," "Her Cross," and "Awaiting the End," of which either Aldrich or Bret Harte might be proud. As was only natural for one whose innate sensitive disposition was accentuated by disease, his poems show him alternating between the most extravagant buoyancy and the blackest depths of despair. Thus, with a knowledge of his sad history, one reads his crisp, bright society sketches, and his easy flowing, well-handled humorous efforts, with as mournful an interest as the verses which express his earnest and manly thoughts as the gloom of his near future overpowers him. Here there is nothing of the lugubrious wailing of the lovelorn, fledgling poet, but the simple outpouring of a breaking heart.

LECTURES ON CATARACT: ITS CAUSES, VARIETIES, AND TREATMENT. Being Six Lectures Delivered at the Westminster Hospital. By GEORGE COWELL, F.R.C.S. With Illustrations. London: Macmillan & Co. 1883.

THIS treatise is meant for the use of students, and discusses the subject in an attractive style.

A NEW DEPARTURE IN THE THEORY AND PRACTICE OF MEDICINE. BY C. A. HARDY, M.D., Graduate of the University of Pennsylvania. New York: P. O'Shea, 45 Warren Street. 1883.

IT would be impossible for us, in the small space allotted, to enter into the several details and arguments promulgated by the various theories presented. The author says: "For over thirty years I have entertained the belief that the nerve-force was some form of electricity or galvanism; that there was more than muscular or mechanical action in the heart-throbs; that nervous manifestations indicated some form of magnetic force besides the functional action of the organs." Regarding the nerve-force or vital principle, he likens the brain to a magnetic pile, in the cells of which the nerve-force is produced by the action of oxygen upon the constituents of the blood; and in conjunction with which, also, the spinal cord and ganglia and the sympathetic system act as reservoirs for storing up and distributing it. The heart and circulation of the blood is then taken up, the constant motion and action of which is also supposed to be controlled and regulated by the nerve-force generated in the brain-cells, and the derangement of which is followed by disease. The double long and short beat of the heart is, moreover, compared to the positive and negative actions of electricity. In support of these theories numerous arguments and well-founded reasons are offered, most of which will admit of deep study and examination. Chill and its consequent fever are also shown to be due to derangement or great vital depression of the nervous forces, and the subsequent reaction. Upon this principle the treatment of typhoid fever is presented, for which method the author claims the highest satisfaction. Malarial and yellow fevers, and diphtheria, which latter he regards as an erysipelas of the mucous membrane, are also interestingly considered. The chapter on contagion is not the least important. This theory rests upon that applied to the circulation of the blood. Erysipelas and its cure, the action of snake and other poisons, rabies, hydrophobia, etc., are also entered into with much earnestness, together with antidotal and other treatment. Dyspepsia and various gastric affections of the mucous membrane are further noted.

Reports of Societies.

VERMONT STATE MEDICAL SOCIETY.

(Special Report for THE MEDICAL RECORD.)

THE Semi-Annual Meeting of the Vermont State Medical Society was held at the Bardwell House, in Rutland, June 13th and 14th. The meeting was called to order at 11 A.M. by the Secretary, DR. J. S. RICHMOND, the President and Vice-President not being present.

DR. CHARLES L. ALLEN was called to the chair.

The Board of Councillors reported favorably on the application for membership of sixteen gentlemen, and they were duly elected.

DR. J. M. CURRIER offered the following:

Resolved, That the Publication Committee be instructed to insert in future issues of the "Transactions" of this Society the names of the members of the Society.

Adopted.

The Society then adjourned.

The Society was called to order at 1.30 P.M.

The following was offered by DR. FOX:

Resolved, That this association learns with regret of the

DEATH OF DR. CYRUS PORTER,

one of Rutland's most worthy and oldest practitioners, and we hereby tender our heartfelt sympathy to the family of the deceased.

Adopted, and a copy ordered to be furnished to the family of the deceased and the press.

DR. C. L. ALLEN was appointed to prepare an obituary for the annual meeting.

DR. POND exhibited his

SPHYGMOGRAPH

with mirror attachment, showing the pulse on a screen by reflected light; also reported cases of heart disease, including mitral, aortic, tricuspid, atheromatous disease, with characteristic traces of each and photographs of post-mortem appearances. He also exhibited a rare specimen of atheroma of the arch of the aorta, having a pulse like "Kussmaul's," caused by a longitudinal blocking up of the innominate; also a case of crushed head and brains in which almost every variety of pulse-trace was seen, tracings of diphtheria, mild and malignant, meningitis, typhoid fever, etc.

The Chairman introduced DR. A. J. LONG as a delegate from the Medical Society of the State of New York, and he was invited to participate in the discussions.

DR. CHARLES S. CAVERLY read a well-prepared paper on "Tubercle Bacillus of Koch."

DR. A. T. WOODWARD presented

A COMBINATION SPECULUM

of his own construction, for examining the rectum and female urethra, also a modification of the "Smith-Hodge" pessary which he has recently made.

In the discussion which followed DR. Woodward's paper, DR. KIDDER claimed that there was no danger in dilating the female urethra, that he had repeatedly dilated it its whole length, and had had no other trouble than temporary paralysis; that dilatation with the forefinger will cure tenesmus.

DR. WOODWARD earnestly protested against more dilatation than was absolutely necessary. The meatus only should be dilated ordinarily. There is great danger of cystitis, paralysis, etc., from full dilatation into the bladder.

An obituary notice of Prof. S. W. Thayer, late of Burlington, prepared by DR. H. H. ATWATER, was read by the Secretary.

An obituary notice of Dr. R. W. Clark, late of Georgia, was read by DR. F. RUGG.

DR. EDWARD S. PECK, of New York City, read an interesting paper on the

USE OF JEQUIRITY IN CASES OF INVETERATE PANNUS OF THE EYEBALL,

based on an experience of seventeen cases (see p. 29).

The Society then adjourned to 7 P.M., at which time DR. C. L. ALLEN read a paper on

OLD AGE,

of which the following is an abstract:

Life, death; enjoyment, suffering; health, sickness—these are the never-ceasing objects of care and solicitude with every member of the human family. To secure the former and avoid the latter is the never-ending struggle of humanity. Individually or collectively, whatever is undertaken in the material world, whatever is manifested in the moral world, is but the evidence of this struggle—a struggle which will continue as long as sickness, suffering, death, are realities.

To live, to live happily, to live for a long time are the most universal desires of mankind. Yet there are no objects toward the attainment of which efforts are more blindly or less efficiently directed. To live happily, we may perhaps say, requires no effort or foresight on our own part. To live happily, without thought or care, may be the lot of some, but commonly it is the result only of long, well-directed, and unwearied labor, and hence really enjoyed by but few. To live for a long time requires such a rare combination of mental, moral, and physical qualities that only an occasional example is found.

The efforts of science have not yet been able to break the impenetrable seal which conceals the secret of life. We perceive life, we prove it, we enjoy it; its nature remains unknown, its essence beyond reach. But its principal acts, its most important phenomena are known and appreciated. These phenomena constitute the most solid basis for the study of man, in his totality, in his succession, in his growth, and in his decline. They show us that the life of man is one continual progression, and not only that, but a progression onward and upward, and of progression onward and downward.

The life of man has been variously divided into periods, or "ages," according to the object, fancy, or caprice of those who made the divisions. Several divisions were mentioned. The evolution of the human organism is not accomplished in all with the same degree of rapidity. There are old men at thirty years of age. On the other hand octogenarians are young and flourishing, by the vigor of their constitutions and the proper regulation of appetites and passions. The concatenation of acts by which life operates is invariable, but the rapidity of their succession is varied by a crowd of circumstances, some inherent in the being himself, others exterior to him.

At each period of life there is a corresponding form of health, a general manner of living. Idiosyncrasies change, temperaments alter, vital movements concentrate toward different cavities at different ages.

The infant is, as it were, a living sponge. The tissues are all soft, delicate fibres saturated with moisture, readily and rapidly losing or gaining in weight by the simple subtraction or addition of water. No organ or function escapes change as the necessary result of age.

The changes produced by age were then described as found in the bones, muscles, ligaments, skin, and hair. Then were noticed changes in weight, stature, digestion, nutrition, the ability to endure variations of temperature; changes in the circulation, including hæmatosis, and in the respiration. The effects of age were exhibited in the lymphatic system, in the nervous system, in the senses, in the intellect, in the reproductive function, and their organs. All these changes are in a constant progression in one definite direction. Commencing as near to a liquid condition as is compatible with life, it terminates in almost complete solidity. If death is the natural result of these changes, if they must all take place in a limited time,

can we know the limits of that time? Is there any definite period which is the physiological term of a man's existence? How many years ought a healthy man, with a sound constitution, to live? Nature is parsimonious in her labors, furnishing us with infinite variety of individual development, but with unity of type and design. Each class has its peculiar mode of evolution; each species has its definite period of existence; each stage of development bears a definite ratio to the whole life of the animal. Among mammals, to which class man belongs, the natural duration of life is from five to eight times as long as the period of growth (Hourens). By this standard the duration of man's life should be at least one hundred years, and ranging from that to one hundred and sixty or two hundred years. Instances were given of longevity ranging from one hundred and fifty to one hundred and seventy-five years.

But whether life be short or long, whether accident, disease, or physiological decay be its termination, death is sure to come—Death, the greatest mystery of nature; death, that phantom without a body, whose name alone stiffens us with terror; death, that horrible image of destruction, the idea of which, like a harpy, comes to infest all the courses of the banquet of life. Morals aside, man is certainly, in respect to his organic life, bound by a law of destiny more dire than that to which other animals are subject. Although of an inferior rank, they at least have pain without reflection, death without foreboding, an end without fear and without regret. With enlightened and intelligent man the thought of death is often present, openly or secretly, and the more often and more openly the older he grows. To the young man death seems so far off, and the cares, the duties, the joys, the incessant whirl of business are so engrossing that he has little thought and less fear of death. But to the aged man, whose mind has been enlightened by education, by reflection, by observation, by experience and contact with other intellects, the thought unceasingly recurs, and almost always with terror. Yet this fear of death is not simply the feebleness of age or weakness of mind. It is the instinct of preservation implanted in us by nature herself, which repulses the idea of destruction, and which acquires in the aged a power more despotic than in earlier years. In vain does the body waste; in vain do infirmities, cruel and painful, show themselves; in vain do the resources of the economy become exhausted; in vain does philosophy eternally repeat that life is fatiguing and vapid, that it is a heavy burden, that it is a tissue of weariness and evil, that it is a sombre tableau of misery and anguish. The old man accepts it all; he wishes still to live. Why does man so desire to live—so fear to die? Simply on account of his ignorance of what may be after death. We have no direct, sensible physiological evidence, even of existence after death, to say nothing of the modes or relations of that existence. It is true that the vast majority of men believe that to this short, material life succeeds another life, freed from organic molecular disaggregation, a life without relations with the constructive atoms of the material world; a life without change, without end, without death. But, revelation aside, neither reason, nor analogy, nor experience, nor the memory or testimony of men; neither inductive evidence, nor the action of the laws and metamorphoses of nature can enlighten us in the least upon this great subject. All is unknown, forever unknown; forever there is the silence of the tomb. This awful mystery may perhaps conceal the mysteries of another life, but the veil which covers it is as sombre as it is impenetrable. We walk by faith, by desire, by hope. We feel confident that Nature, however inflexible and implacable her laws, will not deceive us. She has given us intelligence, high aspirations and hopes, unlimited cravings for improvement, for perfection. She has implanted within us an innate desire, a powerful instinct, which excites us to hope for something permanent, something everlasting, beyond and above this finite world.

If the few short days we live here are all of our existence, why inspire us with a chimerical inquietude concerning a future never to be realized? Why poison all our joys by the sad reflection that they are so soon to end? Why embitter our days by the gloomy comparisons of what we are with what we proudly hoped to be, of what we have with what we fondly wished to possess? No, Nature, ever attentive and provident for all her creatures, will not cheat her most cherished children. If in a material and physical point of view science cannot demonstrate a future existence, neither can it demonstrate the contrary. Hence we are free to rely upon moral, upon psychological proofs. Proofs of sentiment, the natural tendencies and aspirations of man, evidences of the heart—these amount to almost if not complete moral certainty. For the individual, in this life, we have growth, maturity, decline, and decay. In the next, we hope for progress, ever onward, ever upward, improvement upon improvement, development following development in a never-ending series. For the race the progress here is always onward and upward; there is no decline, no decay. Perfectibility is an attribute of humanity, and each generation of mankind is becoming happier, wiser, and better, and enjoying life longer than its predecessor.

Life is short but the list of diseases is long. Old age and disease appear to be twin brothers, forever inseparable. The contrast between the diseases of early life and old age were dwelt upon. Then the pre-requisites of a long life enumerated; but these being only partially under the control of the individual most concerned, are not elements in the real problem to be solved. For the man approaching or passing the epoch of the plenitude of his physical forces, to him who, having arrived at the highest pinnacle of organic energy, can hereafter only go downward, the question, urgent, momentous, engrossing, is, What can now be done to prolong life, to retard the rapidity of descent down the slope of life, to smoothe the pathway so that the descent may be without shocks and jars, without pain and sorrow? The learned, amiable, and good Reveillé-Paëise lays down four universal and all-important rules: 1st, Know how to grow old; 2d, Know one's self; 3d, Arrange wisely the habits of life; 4th, Combat disease at its commencement. To these I would add another equally conducive to long life, and more important than any in its bearing upon the happiness of the aged: *Rule 5th*, Have education, general intelligence, culture.

As age advances the well-trained intellect, the richly stored, highly cultivated mind feels no weariness, but enjoys quietly and fully the fruits of his former labors. How often, in my intercourse with the aged sick or ailing, have I had occasion to notice the difference in the happiness of two of equal age, placed in circumstances almost identical, both endowed originally with good constitutions—the one educated, cultivated, enjoying scientific research or philosophic meditations, the other not ignorant, indeed, but pleased with only light, transitory or sensational literature; the one contented, happy, and a source of pleasure to all around him, the other fretful, morose, complaining, neither enjoying life himself nor allowing others to do so; the one retaining intelligence clear and unsullied to the last moment, the other gradually losing his mental faculties long before death occurs.

How beautiful, how sublime is the sight of the aged man of culture, enjoying his "*otium cum dignitate*." He has lived, he has flourished, he has played his part, perhaps, in public affairs, and now, respected and revered by all, he can pass serenely along the downward current, happy in the enjoyment of his intellectual faculties, in the remembrance of his early achievements, in the hope of a more brilliant hereafter.

The Executive Committee made the following assignment of subjects for the annual meeting, to be held at Montpellier, October 10 and 11, 1883: "Liver," Dr. S. S. Clark, St. Albans; "Blood-stains," Dr. E. S. Munger, Put-

ney; "Localization of Cerebral Symptoms," Dr. X. H. Towsley, Rutland, and Dr. John M. Currier, Castleton; "Obstetrics," Dr. H. R. Jones, Benson; "Physicians' Testimonials," Dr. O. W. Sherwin, Woodstock; "Localizing Bullets" (new method), Dr. S. J. Allen, W. R. Junction; Obituary Notices: "Dr. Cyrus Porter, late of Rutland," Dr. C. L. Allen, Rutland; "Dr. J. O. Crampton, late of Winooski," Dr. Richardson, Winooski; "Dr. John L. Chandler, late of St. Albans," Dr. O. F. Fassett, St. Albans.

The thanks of the Society were voted to the gentlemen who had presented papers. At 9 P. M. there was an adjournment to the banquet.

The physicians and druggists of Rutland entertained about fifty members of the Society at the banquet. The large dining hall of the Bardwell was filled to its utmost capacity by the doctors and élite of the city. The banquet was elaborate and sumptuous. After the feast Dr. L. M. Bingham, President of the Society, led off with a speech and introduced the toast-master, Dr. C. L. Allen. Sentiments and speeches followed until a late hour. On Thursday the doctors and druggists chartered a special train of cars and took the Society and other invited guests to the West Rutland Marble Quarries. On their return, by special invitation of President Merrill, they visited the Howe Scales Works.

At 1.30 P. M. the Society was called to order and listened to a lecture by PROF. J. L. LITTLE, on Bigelow's method of crushing and removing stone from the bladder. Prof. Little exhibited instruments and detailed a recent successful operation on a patient seventy-seven years old. Dr. Little has operated for stone in the bladder sixty-six times, seven times by Bigelow's method. His shortest time for operating, fifteen minutes; longest, one hour and forty-five minutes. He says Bigelow's is the safest operation.

The thanks of the Society were tendered Dr. Little.

Dr. E. S. Peck, of New York, was made an honorary member of the Society.

THE ARMY MEDICAL MUSEUM AND LIBRARY.

The following resolutions were adopted:

Whereas, It is well known that the interest and advancement of medical science in the United States have been largely promoted by the valuable collection of specimens in the Museum of Military Medicine and Surgery of the Medical Department of the United States Army, as well as by its magnificent Library of rare and valuable books and by its numerous publications; and believing that all national works of this sort that so eminently contribute to the interests of humanity and to the welfare of our people should be protected and encouraged by the Government and people of this country; therefore,

Resolved, That the State Medical Society of Vermont will exercise all proper influence with Congress to provide for the Library of the Surgeon-General's office and Army Medical Museum an adequate appropriation to allow for the erection of a suitable fire-proof building for the safe and permanent preservation of the said materials, which are now exposed to constant danger from fire and loss.

Resolved, That we also urge upon Congress the propriety of said Museum and Library being continued under its present management, and that we earnestly recommend that the Library be maintained separate from the Congressional Library.

Resolved, That we further petition Congress to make suitable pecuniary provision for completing the publication of the "Index Catalogue" of the Library of the Surgeon-General's office.

Resolved, That a committee be appointed to convey to Congress the views of this Society upon the matters hereinbefore set forth, and that each member of our Society be requested to use his influence with the delegation in Congress.

Resolutions of thanks of the Society were voted to the

physicians and druggists of Rutland, for their reception and entertainment, to the proprietors of the Marble Quarries, the Howe Scales Works, and to the several railroads for courtesies received.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

LORD WOLSELEY AND THE ARMY MEDICAL INQUIRY—
THE OXFORD PROFESSORSHIP AND VIVISECTION.

LONDON, June 20, 1883.

THE Army Medical Inquiry Report continues to excite interest and criticism. The closer Lord Wolseley's evidence is examined the more unjust does it appear. During the campaign he officially expressed his satisfaction with the medical service in his telegrams and despatches. After the campaign is ended he officially repeats the substance of verbal complaints he made in Egypt, most of which ought to have been made to another department. It is really not putting his action in a false light to say that he appears to have been somewhat double-faced. The most charitable supposition is that his lordship's head has been turned by his peerage and his pension, and the opposition to the latter has doubtless not improved his temper.

It was manifestly unfair to contrast the army hospital at Cairo with Lady Strangford's. The former was dependent upon army officials for supplies of every description, which could only be procured through the ordinary channels. The latter was supported by private resources and its sick attended by a civilian medical staff. The son of a London physician—Dr. Sieveking—went out to work in its wards.

The necessary funds for building a physiological laboratory, etc., at Oxford have been voted by a very narrow majority (3 in a meeting of 193 members of convocation) on Tuesday last, June 4th. The opposition was partly on the score of economy (£10,000 being asked), but mainly on the ground that vivisections would be performed. The opposition to vivisection is plainly on the increase. It is, of course, chiefly in non-medical circles that this is the case, though it is an interesting fact that a pamphlet on the subject for private circulation was lately issued by a distinguished army surgeon, in which the author—Dr. C. A. Gordon, C.B.—maintains that no discovery has ever been made by vivisection that has ever proved of direct service in medical treatment that could not have been made without it. Dr. Gordon states that he commenced his study of the subject as one prejudiced the other way and that he has arrived at his conclusions through a dispassionate investigation of the literature of the subject. I think your readers will agree with me that the total abolition of vivisection is an event not to be desired. The restrictions that have been placed upon it in this country are no substantial detriment to real scientific investigators and were fully called for by the needless cruelties that have been perpetrated in the name of science. I could name at least one well-known physiologist in this country who is utterly callous as to inflicting *unnecessary pain* on animals, who only employs anesthetics to keep the animals quiet and prevent them from biting, scratching, or otherwise annoying him, and who confessed before the Royal Commission on Vivisection that he had no feeling whatever for the animals he tortured. I refer to Dr. Klein. Some experiments on scorpions, made by Mr. C. Lloyd Morgan in Germany and deliberately described by him in *Nature* (February 1, 1883), were revolting in their cruelty. Mr. Lloyd tortured them in various ways to see if he could induce them to commit suicide. Amongst other ways he placed them in burning alcohol, in concentrated sulphuric acid, and burnt phosphorus on them, etc.

Mr. Lloyd admits himself that the phosphorus experiment was sickening. It is difficult to see what scientific value such brutalities can possess. It is such men and such deeds that bring odium on scientific and humanly conducted vivisection by such men as Foster, Sander-son, etc.

DOES THE RETENTION OF DEAD TEETH IN THE JAWS EXERT AN UNFAVORABLE INFLUENCE ON HEALTH?

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: The above question is the heading of a letter by Dr. Samuel Sexton in your issue of May 12, 1883, to which, if you will kindly allow me the space, I beg to answer.

In ninety-nine cases out of every hundred I should say yes, they do "exert an unfavorable influence on health," and for the following reasons: It is a well-known and generally understood fact that the dentine of a tooth (which forms the bulk of the tooth-structure) and the enamel receive their nourishment from the pulp; that the amount of organic material in dentine is about twenty-eight per cent., and that of the enamel from three to five per cent. When the pulp is destroyed the nourishment of this organic portion is cut off entirely, with the possible exception of a very limited amount, which may be furnished from the periosteum through the cementum, which surrounds the root; consequently the death of the organic portion of the dentine and enamel must necessarily follow. This dead substance remains as a part of the tooth-structure to constantly decompose. In the structure of the tooth the organic portion is united directly from the periosteum to the pulp, through the cementum and dentine alike. Consequently the dead and putrefying portion in the dentine is constantly in contact with the organic portion of the cementum, which is still living; that, under circumstances which determine an excessive flow of blood to the part, such as a severe cold, a blow upon the tooth, or a severe wrench in biting upon some hard substance, excessive absorption of the putrefying portion by the living takes place, I hardly think will admit of a doubt. No matter how perfectly the dead pulp may be removed and the canal filled, this condition still exists. The fact, however, is that the pulps *cannot* be perfectly removed from one-half the teeth where it is attempted, but a portion is left in the canals to putrefy and assist in the disturbance which too often follows. Another feature of the case is that not one-tenth of the teeth in which the pulps are dead is any attempt made at their removal. If any one will consider for a moment the number of people who have no dentistry done, and those who have it poorly done as compared with those who have the best dental services it is possible to obtain, they will, I think, readily admit the truth of the above statement.

The conclusion then is, that *no* pulpless tooth is absolutely sure to not make trouble. From the most perfect operation of removing the dead pulp and filling the canals (which by the way, should never be done with gold) to those where the entire dead pulp is allowed to remain in the teeth, there is more or less of a periosteal irritation, which is almost constant. It is true that the tooth, or teeth, may not be painful, but some remote part, such as the eye, or the ear, may be affected, or a neuralgia extending over the side of the face and head may be the result. Many cases like these have come under my observation, where the most perfect dental work had been done. In many cases, however, pulpless teeth, after treatment, are kept in the mouth for many years, and render good service without apparently producing any pain or distress whatever. Others will, upon the slightest provocation, become sore and very painful. This, however, in most cases can be sufficiently overcome by proper treatment, to warrant their retention, provided they are very useful. But when, after consul-

tation, it is determined that the irritation produced by such teeth is more injurious to the patient than can be overcome by their service in mastication of food or otherwise, in my judgment they should be removed at once. I might cite many cases bearing directly upon this subject, but for the present the above will suffice.

I am, very truly yours,

FRANK ABBOTT, M.D.

22 WEST FORTIETH STREET, NEW YORK, July 9, 1883.

MEDICAL MATTERS IN NEBRASKA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: You have doubtless received ere this a summary of the proceedings of the Nebraska State Medical Society, which met at Lincoln recently. In many respects it was a success, but as to any exposition in medical science it was lamentably deficient. Reports of sections were called for by the President, and for the most part answered by the Chairman of Committee in an avowal of ignorance that he was on the committee. Dr. Mansfelde, Permanent Secretary, made an exception to this, in the presentation, with notes, of a four-pound cystoid kidney. Discussions on diphtheria and hysteria were rambling and profitless—the report of a case of aconite-poisoning proved to be no such thing, and the only paper read (on vaccination) was a history and very incomplete. Discussion revealed the fact that non-humanized virus is in disrepute, and chiefly by reason of imperfection in the virus; but anything looking toward remedy of this was not effected. No action was taken in regard to ethics, in dispute at the National Association, but a strong supporter of the Association's action stated in a large gathering, that the sooner all *code* was abolished, the better. This I believe to be the general drift. The Committee on Medical Legislation reported informally that their efforts came to naught. In reality, those having it in charge were not the peers of homeopaths in the matter of *lobby*. The leading man is but a respectable fossil.

Being in hearty sympathy with the good work you have done, looking toward the elevation of the standard of medical education, I would like to note the advent of another medical school—in this West, to wit, the Medical Department of the University of Nebraska at Lincoln. It is in many respects a still-birth, for although the State Medical Society met almost in the shadow of this university building, no mention was there made of the same, while many seemed to think for the present it would not amount to anything. The Society, in its rounds, visited the Home for the Friendless (inaugurated last January), wherein the new school finds its hospital. This building is quite beyond the city limits, and at the time of our visitation, while not seeing any patients, we were told there was *one*. There is no excuse, in the light of education, for the school at all, and I take it the only incentive is that which too commonly exists: the furtherance in position of local medical men, who become associated with it. The Medical School at Omaha is fairly established, so its promoters inform us, but the position you took toward the same was undeniably just. The establishment of these schools is heralded by the press and public, even as they do any new institution, in a very gross and material way. Too often these are *institutes*, cure-all establishments, but all aflame with their disinterested greatness. It is the spirit of "boom," which at present is soul and body of our social fabric.

A feature of this year's State Society meeting was the simultaneous gathering of the homeopaths. While no reference was made in our meetings to distinctive position, our neighbors were brim full of it, and placed themselves on record. In striking contrast is it with the attitude exhibited at Albany by the New York homeopaths in their recent annual meeting. Their President, Dr. Mitchell, stated in his address that "our doses can vary from the largest old-school potion to the highest of our

infinitesimals," that the regulars "use our drugs in their true relation to disease," "understand the methods of palliation better than we do," and, moreover, that "there are cases where our law fails, or is inapplicable." Commenting upon which the *Springfield* (Mass.) *Republican* said, "It is plain if Dr. Mitchell fairly represents his own school, there is no longer any necessity for its separate existence." Here Dr. T. C. Duncan, of Chicago, in what is termed *the address*, stated, that "the difference between the two schools is as wide as ever." "Judging the future by the past, the union of the two schools is far remote," while "union could be brought about only in the recognition of their principles." Perhaps Dr. Duncan does not fairly represent his brethren; still, it is probably not their desire to sink distinctive titles at least, for with most of them this would be an appalling disaster.

Yours,

NEBRASKA.

THE QUESTION OF INEBRIETY AND DISEASE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: That advocate, *par excellence*, of the disease theory of inebriety, Dr. Crothers, again comes forward in a late number of THE RECORD, with a synopsis of cases, from which he deduces what he believes to be facts in support of his views. I see in none of them anything but a repetition of the old story of deficient will-power in the presence of an evil. His first case is that of A. B—, a prominent physician, by the way, who had graduated with honors, fell through the ice into the water, which event was followed by pneumonia, and this in turn by a condition of nervousness, for the relief of which he began the use of spirits! Verily, his knowledge of *materia medica* must have been meagre! Of course, his "nervousness" gradually required larger doses, and as spirits was the best sedative he could find, notwithstanding his efficient medical training, he became a confirmed inebriate—a coward, finally, in principle and in morals, for he endeavors to throw the blame from himself in that he says "his inebriety began from some physical condition, and that through the treachery of friends he was made worse." He finally landed in prison, where, in the absence of his scientific remedy for nervousness, he seems to have recovered both from it and his intemperance. Dr. Crothers thinks the pneumonia was followed by acute asystolism. This may be so, though it is hypothetical, and the treatment certainly questionable.

The second case, C. O—, was also a medical student of long training, and for some time professor in a medical college. One day he became "accidentally (?) intoxicated," and soon after was forced to resign, went from bad to worse, and finally brought up in an insane asylum, a lunatic from the excessive use of spirits. It transpires, however, that two years before he became "accidentally intoxicated" he had habitually made use of brandy for the production of sleep. It is a singular circumstance that, though a medical professor, he failed to find any remedy so effectual for this purpose as brandy. This gentleman too, seems to be blind to the true cause of his weakness and says, "his inebriety began from neurasthenia and heart exhaustion." The third case, that of a theological student, runs about the same course, and ends with the same sort of an apology. "He began to use spirits in the seminary for a tonic, used it quite freely while supplying his pulpit, but always at night." These are only a few of the doctor's synopsis of cases, and while I say nothing of the palpable fact that they represent an entirely exceptional class of inebriates, we can even in these selected cases plainly see the moral forces at work in their causation.

We have been told of heredity as being active in the production of drunkenness. That this is a prolific cause I do not doubt, but that it is wholly, or even in a great

degree a physical heredity, I do not believe. The inebriate is an inheritor, to some extent, of his forefathers' special curse; not of this particular sin necessarily, but rather of the atmosphere in which his progenitors lived, of the moral conditions which surrounded them, of the general depravity of tone which as a rule marks the homes where are reared the young inheritors of the parents' weakness. The child reared in the home where profanity is daily used and where no regard is had for good morals is very likely to grow up in conformity with his teaching; that one born into the home of the inebriate, subject to such environments as surround him there, will do the same. The heredity of influence and surroundings is a potent factor in the production of inebriety.

But suppose for a moment we allow that inebriety is always a disease, may we not with equal propriety assume that all sin—or that we are used to call sin—has a physical basis; that what we have heretofore regarded as a deficient moral status has really its origin in some congenital or acquired moral defect? Is it not as reasonable to suppose that an act by which one person commits violence upon another, or takes that which is not his own, has its origin in a physically diseased condition, as that this is true of the person who commits violence upon his own mind and person by subjecting them to the overwhelming influence of intoxicating drinks or narcotizing drugs. It seems to me that this is the legitimate conclusion, though the logical result of the argument would be that *all* action, right or wrong, has a physical basis, healthy or diseased, but for which in either case the individual is not responsible.

Dr. Crothers dwells frequently upon what he calls "obscure" causes. I confess they are so when viewed as he views them. It is doubtless true that obscurity will be thrown around any study when we try to bend facts connected with it to any single idea. We can study inebriety neither as moralists nor scientists wholly, but must be prepared to recognize the fact that some cases depend upon one cause, some upon another. That there are cases of inebriety that depend upon physical causes I am ready to admit, and have done so; but to say that "it is always a disease" is a dogmatism without even the redeeming quality of truth.

J. B. STAIR, M.D.

SPRING GREEN, WIS.

FISKE FUND.—The Trustees of the Fiske Fund, at the annual meeting of the Rhode Island Medical Society, held at Providence June 21, 1883, announced that they had made no award on the subjects proposed for the present year. They propose the following subjects for the year 1884: 1. "The Origin and Progress of the Malarial Fever now Prevalent in New England." 2. "Original Investigations in Household Hygiene." For the best essay on either of these subjects worthy of a premium they offer the sum of \$300. Every competitor for a premium is expected to conform to the following regulations, viz.: To forward to the Secretary of the Trustees, on or before May 1, 1884, free of all expense, a copy of his dissertation, with a motto written thereon, and also accompanying it a sealed packet, having the same motto inscribed upon the outside, and his name and place of residence within. Previously to receiving the premium awarded the author of the successful dissertation must transfer to the Trustees all his right, title, and interest in and to the same, for the use, benefit, and behoof of the Fiske Fund. Letters accompanying the unsuccessful dissertations will be destroyed by the Trustees, unopened, and the dissertations may be procured by their respective authors if applications be made therefor within three months. Job Kenyon, M.D., River Point; Oliver C. Wiggins, M.D., Providence; Horace G. Miller, M.D., Providence, Trustees. Charles W. Parsons, M.D., Providence, Secretary of the Trustees.

New Instruments.

TONGUE DEPRESSOR AND NASAL SPECULUM.

By D. H. GOODWILLIE, M.D.,
NEW YORK.

FIGURE 1 represents a new tongue depressor with the following description, viz.:

The portion that touches the tongue is concave, and as the base of the tongue is nearly always convex, it fills up this concavity when first placed on it. When pressure is made on the tongue it flattens out under the depressor and produces a vacuum in the concavity, thus holding it firm upon the tongue, which can now be drawn forward, or laterally, without any discomfort to the patient. When the tongue is depressed sufficiently, then let the shank, which is slender, rest on the lower incisor teeth.

FIG. 1.—Tongue Depressor and Speculum.

The handle is held to the depressor by a thumb-screw, and is so arranged as to hold it on either side, or in front of the chin. In some cases the handle can be so placed as to come under the chin, and so make the depressor self-sustaining. The depressors are of two sizes, for adults or children.

The advantages are that it depresses well the base of the tongue, and holds it securely by the suction power, and without any discomfort to the patient.

The handle is conveniently held by operator or patient, and to one side of the mouth. It can be easily kept clean.

FIG. 2.

FIG. 3.

FIG. 2.—Folding Tongue Depressor.

FIG. 3.—Folding Pocket Depressor.

Figure 2 represents a folding tongue depressor, having two sizes.

Figure 3 represents a folding pocket depressor, having two sizes.

The nasal speculum is only introduced here to show the best way of using it. A description was given of it in THE MEDICAL RECORD some time since. The instrument is made by Geo. Tiemann & Co., N. Y.

A MODIFICATION OF LORING'S OPHTHALMOSCOPE.

By J. B. McMAHON, M.D.,
NEW YORK.

SOME five years ago Dr. Loring brought to the notice of the profession an ophthalmoscope, carrying fifteen lenses on a disk and four on a movable quadrant. In the number of possible combinations and the ease with which their values could be read, nothing was left to be desired.

In none of the forms of this instrument hitherto in use has it been practicable to rotate the quadrant without moving the instrument from the eye and so interrupting the examination.

To obviate this difficulty, and, at the same time, by a slight alteration in the arrangement of the lenses, to get a much more efficient "fine adjustment" has been the object aimed at in the instrument to which I would call the attention of your readers.

The instrument has the ordinary tilting mirror. The main disk, as in Loring's, has an aperture and fifteen lenses, ranging from, +1 D. to +7 D., and from -1 D. to -8 D. The second disk has four lenses, $\pm .5$ D., + -16 D., and an aperture arranged as shown in Figure 2. The cut indicates also the five small

FIG. 1.

holes in which the pin of the centring spring plays. This disk serves as a cover for the first, its own lenses being protected by a metallic sector, partly cut away (*vide* Fig. 1).

The main disk is revolved by means of a milled edge the second, by a milling raised on its posterior surface just within its edge. Both disks are centred. The centring springs, one of which is seen in Fig. 1, surrounding the thumb-screw, secure a perfectly smooth, uniform, and independent motion of the two disks.

The instrument is light and compact. Its mechanism is simple. The glasses are efficiently covered. All the numerous combinations can be obtained without removing it from the eye, and with as much ease and certainty as in using the single disk ophthalmoscope.

For ordinary work the main disk suffices. If, however, a nicer determination of an error of refraction be desired, a slight movement of the second disk, in either direction, increases or diminishes, by a small refractive interval (.5 D.), the power of the lens of the main disk that is in use, thus affording a true "fine adjustment." In doing this, the finger is slipped from the milling on the edge of the first disk, to bear lightly on the milling and posterior surface of the second, and so rotate it, the motion being a very easy one.

FIG. 2.

The use of the combinations in which the ± 16 D lenses take part is quite simple. For example, the revolution of the main disk gives $+7$ D. A movement of the second gives $+7.5$ D. Both disks can now be rotated simultaneously, still in the same direction, the resulting combination being $+8$ D. The higher combinations are obtained as in Loring's, by a continued revolution of the main disk. The reading of their value is practically the same in both instruments.

As so much depends on the accuracy of the mechanism, it is but just to add that Meyrowitz Brothers, after the expenditure of much time and labor, have succeeded in making the instrument at once handsome and reliable.

A PRACTICAL AND SIMPLE WAY TO MAKE THOROUGH APPLICATIONS OF POWDER TO THE POST-NASAL REGION.

By T. HAMILTON BURCH, M.D.,

CLINICAL ASSISTANT, THROAT DEPARTMENT, MANHATTAN EYE AND EAR HOSPITAL.

FINDING difficulty in some cases of making thorough applications of powder to the post-nasal region, without covering a great deal of unnecessary sound tissue, I have had Reynders & Co. make me two thin bulbous-pointed

hard-rubber tubes about three and one-half inches long, and in diameter tapering from one-fourth of an inch at base to one-third of an inch at apex (the dimensions will depend upon the size of the nares, and it would be well to take these measurements for the largest size) and perforated at the end; one with an opening looking directly forward, and the other with three openings, one looking forward and one at each side looking backward.

The terminal opening in the latter being one-half as large as the other two. The object being that the stream of powder will be diverted and an equal amount directed through the side orifices, thereby covering as much of the upper pharynx and post-nasal region as is desired. The tubes can be adapted too, and made with a thread so that they can be screwed upon the stopper part of the powder-blower.

This instrument is very simple and practical, and, if desired, patients can be fitted with the proper size and instructed how to introduce it and follow treatment at home.

It is not too much to say that the old way of deluging the whole nasal tract with powder does very often more harm than good. It is hoped by the aid of these tubes to render the application of powder more scientific than heretofore. The accompanying illustration will give a better idea of the instrument than my article.

New York, June 29, 1883.

THE MEDICO-LEGAL JOURNAL.—We have received the first copy of this new journal. It is published under the auspices of the Medico-Legal Society and contains papers read before that body. It has a well-filled editorial department. Being the only journal of this character in the English language, it may naturally expect success. The first number promises well.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 30, 1883, to July 7, 1883.

HEGER, A., Major and Surgeon. Relieved from the further operation of paragraph 9, S. O. 55, C. S., Department of Texas, and will return to his station, Fort Clark, Texas. S. O. 69, par. 2, Department of Texas, June 25, 1883.

HAVARD, VALERY, Captain and Assistant Surgeon. Assigned to duty with expedition to complete the survey of the country west of the Rio Pecos, Texas. S. O. 68, par. 8, Department of Texas, June 22, 1883.

RAYMOND, HENRY I., First Lieutenant and Assistant Surgeon. Granted leave of absence from July 14, 1883, to September 1, 1883, with permission to go beyond sea, and resignation accepted to take effect September 1, 1883. S. O. 150, A. G. O., June 30, 1883.

Official List of Changes in the Medical Corps of the Navy for the week ending July 7, 1883.

LEACH, T. W., Medical Inspector. Detached from the U. S. S. Tennessee, and as Fleet Surgeon of the North Atlantic Station, and placed on sick leave.

RHOADES, A. C., Medical Inspector. Detached from the Naval Academy and ordered to the U. S. S. Tennessee, and as Fleet Surgeon of the North Atlantic Station.

Medical Items.

MAY THE PROFESSION DEFY PUBLIC SENTIMENT?—An answer to the question which heads these remarks presupposes the profession to be as one man having to do with the great public. No one among the public can gainsay the firmness and independence of the profession as a whole, in the matter of observance of the standard of ethics which it set up some forty years ago. No one, moreover, but will admire its faithfulness to that standard. Is it not time, however, to inquire whether the almost universal condemnation and ridicule which the public is showering on that standard does not suggest a necessity for its revision with a view to conforming it to the spirit of the age, with which spirit the expressions of public opinion show it to be in conflict? And does not the persistence of the American Medical Association, in refusing to recognize the public sentiment in this matter, suggest a suspicion that its firmness and independence have degenerated into obstinacy?—*The Medical Age.*

DR. H. P. STRONG, one of the most prominent physicians in Wisconsin, for thirty years a resident of Beloit, died in that city on June 20th, aged fifty-one. Dr. Strong had received many honors in his own home, among them that of having held the office of mayor for five years. During the war he was surgeon of the 11th Wisconsin Regiment. As a member of the State Medical Society he had filled the offices of secretary and of president, and at the time of his death he was a member of the Wisconsin State Board of Health. Dr. Strong was a brother of William B. Strong, President of the Atchison, Topeka and Santa Fe Railroad, and of James W. Strong, President of Carlton College, Minnesota.

THE POSITION OF THE NAVAL MEDICAL SERVICE AS REGARDS THE CODE OF ETHICS.—In concluding a paper on "Medical Education" before the meeting of the American Medical Association, Dr. A. L. Gibon made the following remarks, which define his position as regards the Code of Ethics, a position which he states receives the approval of the Surgeon-General of the Navy: "It

is almost an insult to the intelligence of the members of the Association to explain that this paper ('Medical Education the Fundamental fact in Medical Ethics') is not intended as a sectarian attack upon the organic law of the American Medical Association, but as this interpretation has actually been given to it by over-sensitive partisans, I deem it proper to reaffirm my loyalty to the code to which I have subscribed, without, however, surrendering the right, which in common with every intelligent man I claim, to criticise what I may think objectionable, and to call attention to the inconsistencies of its avowed adherents who, attempting to observe its letter, injure its spirit. I fail to see why honest advocates of its principles should be placed in an attitude of 'rebellion' for merely defining these principles by the more liberal light of this day. The code properly interdicts any admission of the orthodoxy of the professors of exclusive dogmas, whether of homœopathy, allopathy, hydropathy, or the like, but it nowhere prohibits the intelligent physician giving his advice to whomsoever may seek it, especially when emergencies and the dictates of humanity demand. No one can more energetically discountenance than myself the impossible co-treatment of any case of disease by an educated physician and a charlatan, empiric, quack, or ignoramus however regular, but it is quite another matter when one's opinion is solicited in the interest of suffering humanity. I have yet to hear of any one of our profession soliciting an opinion from any of these, and without such an interchange of views there can scarcely be considered any *consultation* in the sense of the clinical co-operation properly denounced by the code. Any narrower assumption will, as I have endeavored to show in this paper, necessitate the ostracism of these your famous colleagues who have associated as fellow medical members with homœopaths and eclectics in the professional work of the National Board of Health, State boards of health, boards of medical examiners, etc., and I feel assured that the overwhelming sentiment of the American Medical Association will sustain the liberal interpretation I have here given the code."

VIVISECTION IN FRANCE.—Not long ago Professor Brown-Séquard, in lecturing at the "Collège de France," decided to have, as is customary with him, a public demonstration showing the anæsthetic action of carbonic oxide on the larynx. For this purpose he had provided a small monkey. Without administering anæsthetics, Professor Brown-Séquard was about to begin his experiments when a lady suddenly arose and with her umbrella knocked the weapon out of the hands of the astonished scientist. The lady was at once ordered to leave, but declined, and said that she would repeat her action as the only possible protest, so that at least the "barbarous methods of vivisection" should not pass in silence. The usher was equally unsuccessful in appeasing her, and it was only at the instance of a gendarme specially summoned that she consented to leave, which she finally did, accompanied by two of the professor's pupils to the "Commissariat de Police" for mutual explanations. The *Paris National*, in reporting the circumstances, says that the action of the lady was a little too severe, but thinks that France might at least, like England, limit vivisection to classes for original work, and forbid its public displays.

PARASITES IN THE LUNGS.—Dr. Thomas Mann, of Portland, Oregon, writes for information regarding a curious case in which the patient coughs up parasites from the bronchial tubes. The trouble has lasted for a year. Twenty-eight have been coughed up within two weeks. They are coughed up generally along with mucus and blood. The young ones have black heads and a thick white body about one-fourth of an inch long. The mature specimens are longer. The history of the case is as follows: Patient, female, aged twenty-one; native of England; well developed; weight, one hundred and

twenty pounds. Came under observation just one year ago, November 26, 1881. Arrived that day direct from England, suffering from sore throat and nostrils excoriated; breath fetid and offensive; pain in chest just below right and left clavicle; whole length of sternum and muscles of the neck sore to the touch; ulcer on right side of upper part of larynx to the right of epiglottis. All these symptoms have continued. In addition there was menstrual irregularity with hemorrhage from the air-passages at menstrual periods. This, however, is corrected.

Treatment thus far, after trying various remedies without permanent good result: On November 14, 1882, I gave inhalation of terebinthina to anæsthesia. On November 15th two parasites were coughed up, but with so much pain that carbolic acid was substituted as an inhalation, at times using hot water as a vehicle. From twelve to sixteen hours after this one or more parasites are coughed up. When mature ones are coughed up they come in pairs, and pairs are sometimes followed by from two to four young ones. The sputa, I might state, in which the parasites come up smells very strong of turpentine. The carbolic acid inhalations do not seem to be followed with such good effect. The patient is in good condition and attending to business. Dr. Mann has consulted Cobbold, but without getting any light.

LARGE DOSES OF MORPHIA.—Dr. J. A. Rafter, of Holton, Kansas, writes: "In your issue of May 5th appeared an article in regard to morphia poisoning, which has been pretty regularly 'sat down' upon nearly every week since. The dose of morphia supposed to have been taken was something like six grains. Ages of the men, I believe, not stated. A year ago I was treating a case of dysentery; had tried almost all of the usual remedies with unsatisfactory results. The case continually grew worse, and was in an extremely critical condition. Being sent for in great haste one day, on my way to the house I stopped at a drug store and got (by weight) six grains of acetate of morphia and thirty grains of oxalate of cerium, determined to give it a trial (though I had been using small doses of morphia sulph.). The powders were in separate packages. I took from each what I needed—about two-thirds grain morphia and eight grains cerium—Charts No. 2, with directions to give one, and if distress was not relieved in an hour to repeat. I then stowed the larger packages away in a stand drawer in an adjoining room. Called again three hours afterward, found that a mistake had been made in giving the powders. The large ones had been administered instead of the small—oxalate first, and an hour after the morphia. Patient completely narcotized; respiration two and one-half per minute, and the poisonous effect of the drug as well marked as I cared to see it. At once I gave an emetic, following it with strong coffee and belladonna. I administered good-sized doses of the tincture (ten or twelve drops), and repeated often; probably gave a drachm in all. Also gave shower baths and made every exertion possible to rouse my patient; at length succeeded, and, perhaps it is needless to say, he was troubled no more with dysentery. As this case was my own father, and his age over seventy-one years, at that time, I did not regard the case as Dr. Phelps does Dr. Williams's article, 'very funny.'"

HYDROPHOBIA AND THE BITE OF THE COMMON SKUNK.—Dr. Howard Jones, of Circleville, O., writes: "Upon careful inquiry throughout some of the Western States, I have collected the histories of fifty-two cases of bites from the common skunk—*mephitis mephitica*. Assuming these cases to have been accurately related to me, they may be classified as follows: Whole number of persons and dogs reported bitten, 52; number of persons bitten, 25; number of dogs bitten, many several times, 27. Whole number of persons and dogs that died from these bites with symptoms of hydrophobia, 8; number of persons that died from these bites with symptoms

of hydrophobia, 7; number of dogs that died from these bites with symptoms of rabies, counting a dog that was shot to prevent doing injury, 1. The above cases may be again divided into two classes, and each of these may be subdivided as follows: A—1, number of persons bitten while attacking skunks, 16; 2, number of persons attacked by skunks and bitten, 9. B—1, number of dogs bitten while attacking skunks, 27; 2, number of dogs attacked by skunks and bitten, 0. The number of persons that died with symptoms of hydrophobia out of the sixteen in subdivision 1 of class A=0; the number of persons that died with symptoms of hydrophobia out of nine in subdivision 2 of class A=7. The number of dogs that died (or was killed) with symptoms of hydrophobia, out of the twenty-seven in subdivision 1, class B=1. From the above considerations the following conclusions may reasonably be drawn: *First*.—All skunks are not rabid, or, if they are, only about fifteen per cent. of their bites inoculate on men and dogs considered together; while of men bitten, twenty-eight per cent. inoculate and prove fatal, and of dogs bitten, only about four per cent. inoculate. This difference in susceptibility between men and dogs evidently does not exist, and the difference in per cent. of inoculations must be accounted for in another way about to be suggested. *Second*.—When a skunk departs so far from its natural habits as to make an attack with its teeth without any provocation, it is fair to suppose that it is suffering from some disease which has largely changed its nature. This conclusion is strengthened by the fact that out of the twenty-five persons bitten while endeavoring to make angry or kill the skunks (in most instances the animals were in steel-traps), not one suffered any other effects from the wound save the ordinary soreness; while of the nine persons that were attacked by skunks and bitten (in most instances the persons were asleep upon the ground when bitten), seven died with symptoms of hydrophobia, making a mortality of nearly eighty per cent. It may be added that the dog mentioned in division 1, class B, which was killed on account of his having rabies, probably attacked a skunk suffering with the disease. That the bite of the common skunk is, under certain conditions, dangerous, and even extremely fatal, there can be no doubt, and there are many reasons for believing that the disease is identical with rabies in the dog or hydrophobia in man."

THE PHYSICIANS OF NEW YORK CITY AND NEW YORK STATE.—"The Medical Register" for 1883, just issued, gives a list of 2,684 physicians living in the State. The New York City list contains 1,661 names. According to this, the number of (medically) registered physicians in this city is nearly two-thirds of the whole number in the State.

The number of Brooklyn physicians in the list is 510. One hundred and twenty-six of those in the New York list are serving in the hospitals and asylums.

IS TENDENCY TO DEATH DURING PARTURITION HEREDITARY?—Dr. W. Henry Day, in a letter to the *Lancet* asks this question and cites some cases which seem to prove the affirmative. In one case, a mother, grandmother, and great-grandmother all died in their first confinement.

CHLOROFORM NARCOSIS DURING SLEEP.—Dr. W. A. Mansfield, of Champaign, Ill., referring to Dr. Girdner's article on this subject, writes (*Chicago Medical Review*) that he has recently successfully chloroformed a young man during sleep. He produced profound narcosis. The man did not know that the experiment was to be tried.

MEDICAL GEMS FROM "ENGLISH AS SHE IS SPOKE."—A work entitled the "New Guide of Conversation in Portuguese and English" has recently achieved a very wide celebrity. The author, Signor Pedro Carolino, has set forth Portuguese idioms, phrases, and anecdotes with their English equivalent, as he regards it. The result

has been most extraordinary and amusing, the more so as the book is evidently written seriously and in good faith. We append the following formula:

"*For to Visit a Sick:* How have you passed the night?—Very bad. I have not slept; I have had the fever during all night. I feel some pain every where body.—Live me see your tongue. Have you pain to the heart? Are you altered?—Yes, I have thirsty often.—Your stat have nothing from trouble some.—What I may to eat?—You can take a broth.—Can I to get up my self?—Yes, during a hour or two.—Let me have another thing to do?—Take care to hold you warme ly, and in two or three days you shall be cured."

The following comes under the head of Anecdotes.

"A physician eighty years of age had enjoied of a health unalterable. Their friends did him of it compliments every days: Mister doctor, they said to him, you are admirable man. What you make then for to bear you as well?—I shall tell you it, gentlemen he was answered them, and I exhort you in same time at to follow my example. I live of the product of my ordering without take any remedy who I command to my sick."

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE holds its thirty-second annual meeting at Minneapolis, Minn., August 15th, 16th, and 17th. Professor C. A. Young is the President-elect.

BEQUEST FOR A NEW MEDICAL COLLEGE.—The late Dr. Eliphalet Clark, of Deering, Maine, bequeathed several valuable lots of land with which to found a medical college.

THE CONSISTENCY OF OUR MEDICAL LAWS.—The Legislature of the State of New York has decided that "no person duly authorized to practise physic or surgery shall be allowed or compelled to disclose any information which he may have acquired in attending any patient in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon." "It is difficult to reconcile this pronouncement," says the *Medical Press and Circular*, "with the fact that in New York any physician is liable to be clapped into jail and fined \$50, if he does not give public notice that his patient is suffering from infectious disease."

We quite agree with our contemporary in this view. The obligation put upon medical men to notify, without compensation or return of any kind, the existence of infectious disease is an encroachment upon individual liberty which we trust the profession will in time resent.

WOMEN DOCTORS FOR INDIA.—The project for introducing medical women into Bombay is now fairly established, upward of forty thousand rupees having been already subscribed for this purpose. The *Hindoo Patriot* states that the scheme includes the bringing out of women doctors from this country; the establishment of a dispensary for the poor; medical education for female students, through the Grant Medical College; and, finally, the establishment of a hospital for women and children.

DR. SHOSHEE BHOOSUR MOOKES GEE is the name of the President of a new Homeopathic Medical College recently founded in Calcutta, India. The name carries with it a mystical significance well calculated to attract the transcendental.

THE EXTENSION OF VICE.—Professor J. Edwards Smith has devoted a year to the study and discovery of adulterations in homeopathic medicines! When adulteration strikes the attenuated and gossamer fabric of the *sim. sim. cur.* materia medica, we may well believe that vice reaches every fibre of our social system.

DIGESTION AND CONDIMENTS.—How digestion is affected by such condiments as salt and vinegar has been studied by M. C. Hasson, and the results presented in a paper read before the Academy of Sciences, Paris. Taken in moderation these condiments are useful. They pro-

mote the secretion of the gastric juice. But if they are indulged in to excess they irritate the coats of the stomach and render the food more indigestible. The proportion of salt should not exceed 5 to 10 grains to 0.5 kilogramme of meat, and of acid 1 to 4 per 1,000.

YELLOW FEVER AT VERA CRUZ.—For some months yellow fever has prevailed extensively at Vera Cruz, especially among the Americans and Europeans. It is said that one thousand deaths have occurred within the past two months.

DR. A. W. FOOT has just been elected Professor of the Practice of Medicine in the Irish College of Surgeons.

MEDICAL SCHOOLS FOR WOMEN IN CANADA.—Our Canadian brethren have a *penchant* for medical women. A Medical College for Women has been organized in Toronto, and a second one, it is said, is likely soon to be established. A similar college is likely to be organized in Kingston.

THE DELAWARE STATE MEDICAL SOCIETY held its annual meeting at Wilmington June 12th. Dr. Robert M. Hargadim, of Felton, was elected President; Dr. Willard Springer, Vice-President; Dr. George W. Marshall, of Milford, Secretary; Dr. J. W. Sharp, Treasurer.

DRIVING OUT A QUACK.—A man, calling himself Dr. Hale, of Edinburgh, came to Wheeling, W. Va., a short time ago and began to deliver lectures and practise medicine. He also distributed a paper of a low character, called *Health and Home*. He was promptly driven out of the State by the Board of Health.

THE HYPODERMIC INJECTION OF AMMONIA.—The value of intra-venous injections of ammonia has been attested. The following case sent us by Dr. Willis Cummings, of New Canaan, Conn., seems to show that ammonia may be equally valuable given hypodermically. We regret that our correspondent did not assure himself more positively whether the sun or alcohol had the most to do with his patient's prostration. Dr. C. writes: "Was called to see a young man said to be overcome with the heat. Found him in a stable lying on his back, in a perfectly relaxed and apparently anæsthetic state. Was unable to arouse him by pinching, slapping, shouting, or pounding his feet. He had been drinking largely of cider brandy in the morning, after which he took a long ride in the sun, wearing a silk hat. Had been unconscious about an hour and a half before I saw him, which was about 3.30 P.M. Found pupils slightly contracted, head cold, under jaw slightly fallen, extremities cold, and also the whole body, particularly the epigastric region; respiratory movements hardly perceptible to the eye, but little more so to the hand. Heart-beat greatly reduced in force, though pulse was about 100 and very weak. Before I came ammonia had been applied to nostrils and rubbed on back of neck. Cold douches to head, and rubbing extremities had been tried. After using the ordinary means of treatment and getting no satisfactory results whatever, I put four or five drops of ordinary water of ammonia to about a teaspoonful of water, and gave ten drops of this solution hypodermically in the left arm. Within five minutes he was conscious. Before coming to, his cervical muscles twitched a little, and the upper thoracic muscles seemed to contract slightly, making him expire freely with a short, full inspiration. Within the next ten minutes he was walking with the aid of a friend, fully restored to consciousness and able to swear at the pain in his arm. Of course there was a pretty active inflammation at the seat of puncture from the needle. Altogether it was less than ten minutes between the time that he seemed to be at the point of death and the time he was on his feet. He was kept in the shade for about two hours, when he got into his wagon and rode off, a little dazed, but perfectly conscious, especially of the red spot on his arm."

DEALING IN PAUPER CORPSES.—The Chicago Grand Jury has presented to court a strong condemnation of the practice of selling corpses which prevails in that city. It is thought the communication will result in putting an end to the traffic in the bodies of paupers which has convicted the county undertaker. The competition for this position was so great at the meeting of the Commissioners recently, that one party offered to bury paupers for \$1.23 each. The demonstrators of anatomy of the various medical colleges of the city, as well as other men eminent in the medical profession and thoroughly acquainted with the subject, have requested such a change in the system as would give the colleges, in *pro rata* quantities, the material to which they are entitled, the colleges promising to insure the county from expense by paying such prices for the materials as will cover the cost of its transportation to them, and they suggest that any balance arising to the credit of the county be applied to the better care of those bodies that must be buried.

ADULTERATIONS IN LARD.—It is openly admitted by the lard-dealers of Chicago that all lard is adulterated from ten to fifty per cent. In all but the worst grades the adulteration is harmless, being oleo-margarine, cotton-seed oil, vegetable oils, and tallow.

THE FIRST POST-MORTEM IN AMERICA.—Dr. J. R. Quinlan, gives an account of the first post-mortem made in America. It dates twelve years earlier than that which occurred in Massachusetts, and has been supposed to be the first: "At a Provincial Court, held at Patuxent, for the Province of Maryland, September 23, 1657, whereas, it is thought requisite that a view be taken of Henry Gouge, who is suspected to have been brought to an untimely death by his master, John Dandey, and whereas it is conceived that this cannot be had so conveniently in time, as by a competent jury to take a view of said corps, the Court doth order that Mr. James Veitch be hereby empowered to go to the place where the said Henry Gouge was interred, and to call so many of the neighbors as conveniently can be procured, with two *chirurgeons* viz: Mr. *Rd. Maddocks* and Mr. *Emperor Smith*, and after said neighbors and the two *chirurgeons* have taken a diligent view of the said corps, then the said *chirurgeons*, in the view of those present, *are to take off the head of said corps, and, after diligent view and search, to signifie, under their hands, how they find said head and corps, are to cause the said head to be carefully lapped up and warily brought to the Court, with what convenient and possible speed as may be.*" The return of this jury, rendered to the court September 24, 1657, runs thus: "Whereas, according to the order of the court, we have proceeded and diligently viewed the head of the corps of Henry Gouge, and laid open to us by the *chirurgeons*, which was ordered by the court to view and lay open to us. We detest (sic) under our hands that we can see nor find nothing about the said head, but only two places of the skin and flesh broke on the right side of the head, and the skull perfect and sound and not anything can or doth appear to us to be any cause of the death of the said Gouge, and also we do *detest* that we did endeavor what possible in us lay, to search the body of said corps and could not possibly do it, it being too noysome to us all and being put at first into the ground without anything about it, as the *chirurgeons* and the sheriff can satisfie you, this is the truth and nothing but the truth as witness our hands and seals, this 24th day September, 1657. And according to the order we have *delivered* the said *head* in the hands of the sheriff."

INTRA-UTERINE VACCINATION.—Dr. Truzzi vaccinated a number of pregnant women during the last three months of gestation, with a view to determine the protection, if any, afforded to the child. The results were negative, as the children were all successfully vaccinated a few days after birth.

Original Articles.

ON THE PATHOLOGY AND TREATMENT OF CERTAIN FORMS OF NERVE-WEAKNESS.¹

By C. L. DANA, A.M., M.D.,

PROFESSOR OF PHYSIOLOGY, WOMEN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY, MEMBER OF AMERICAN NEUROLOGICAL ASSOCIATION, OF NEW YORK NEUROLOGICAL SOCIETY, PHYSICIAN TO CLASS OF NERVOUS DISEASES, NORTHEASTERN DISPENSARY.

As every physician knows, chronic functional nervous disorders of the neurasthenic and hysterical kind are most difficult to treat with success or even satisfaction. They are apt to be set down as "cranks" and nuisances, the victims of a morbid imagination. This is certainly not a correct or charitable view. Hypochondria, hysteria, neurasthenia, "irritable spine," nervousness, are diseases having a somatic basis as truly as has insanity. And it seems somewhat strange that while every one admits the physical basis of mental disease, physicians are reluctant to admit it for these milder, but most distressing and obtrusive disorders.

Before taking up the subject of treatment, permit me to discuss, as briefly as possible, the subject of the nature and proper classification of these neuropathies.

Nomenclature.—As regards nomenclature, every one has doubtless felt dissatisfied with the term neurasthenia, and especially with its ordinary translation (which is an incorrect one) of nervous exhaustion. Neurasthenia means rather nerve-weakness; and, perhaps, a still more explicit and significant translation is nerve-enfeeblement.

We cannot get rid now of the term neurasthenia, however, and it is not desirable; but it is desirable and possible to give it a much more definite meaning than it has yet had.

I believe that we should use the term nerve-weakness or nerve-enfeeblement, as a general one to include all the different functional neuropathies that are characterized by a diminution in the force-generating centres of the nervous system. It should include, therefore, *hysteria*, mild forms of nerve weakness known generally as *nervousness*, more pronounced and localized forms known now as spinal irritation and *neurasthenia proper*, it should include also such disorders as certain forms of *hypochondriasis*—which the older authors used to look upon with reason as the hysteria of man.

Etiology.—These various neuropathies have certain common methods of development which can be classified as follows:

1. A person inherits or acquires (by overwork, excesses, etc.) a neuropathic diathesis. Some special excess, powerful excitement or injury then induces a train of morbid symptoms characteristic of some form of nerve-weakness.

2. A person of neuropathic antecedents has some slight but chronic local disease (dyspepsia, uterine, ovarian or prostatic irritation, etc.); this, acting as an irritant sets up a train of morbid nervous symptoms. This general disturbance reacts and makes the local trouble worse. The causes thus work in a vicious cycle.

3. Direct, excessive, constant exercise of the nervous centres and mechanisms may lead to an increase of functional irritability with accompanying weakness, or eventually to absolutely less functional activity and

power. Continued disuse of previous actively used functions may lead to impairment in their power also, as we see sometimes in persons who have abandoned their special work or business.

All cases of chronic functional nervousness, neurasthenia as usually described, hypochondria, and hysteria will be found, I think, to have an origin in one or more of the foregoing ways.

Fundamental changes, anatomical and chemical, in nerve-weakness.—Modern physiology throws some light upon our conceptions of the essential changes in the various forms of functional nerve-enfeeblement.

Thus we can say with some confidence that underlying these disorders there are the following conditions:

1. An imperfect tissue nutrition and metamorphosis, a kind of tissue-dyspepsia which results in making the nerve-molecules unstable.

2. Coincidentally there is often, if not always, some derangement in vascular supply. This vascular change, I venture to say, is always an anæmia or a venous hyperæmia; true hyperæmia is not present, except incidentally and temporarily in chronic functional nerve-weakness, since it is always the correlative of increased functional power.

3. Some permanent chemical changes are very likely present. These changes cannot be great as regards the nerve-elements themselves, for all tissues, as long as they act and preserve their identity, must have about the same composition. I doubt if the balance of the chemist will ever tell us what are functional diseases. But the chemical products of tissue activity may be altered, as shown by the character of the excretions.

Referring now to the disturbance in the tissue nutrition of the nerve-centres, the view that the nerve-molecules are in an unstable condition is, I believe, a helpful one, although it may seem somewhat transcendental.

A nerve-centre may be compared (as was suggested by the late Professor Clifford) to a house of cards which is being constantly built up and as constantly knocked down in every functional act. Normally this house of cards has a certain relative stability and is only toppled over by its legitimate stimuli. But in the neuropathic state the foundations are less broad, the superstructure more frail and less lofty. It is knocked down more easily, it recovers itself more slowly; perhaps it can hardly be built up again at all. It is unstable. With such an illustration we can perhaps refer to "molecular instability" and have it convey a just notion of a real pathological condition.

Physiology of nerve-weakness.—The nerve-centres being in the morbid condition just described, give rise to certain vital phenomena which may be described under the head of the physiology or physiological pathology of nerve-weakness.

These phenomena may be tentatively classified as follows. I would not affirm that the divisions are exact or mutually exclusive:

1. A condition of irritable weakness.
 2. A condition of absolute weakness.
 3. A condition of lessened resistance to the passage of nerve-impulses.
 4. A condition in which the higher and inhibitory centres are weakened in power or entirely "shelved off."
1. The condition of "irritable weakness"—an excellent though ancient term. If you partly cut off the blood-supply from a nerve, then irritate it, the response will be

¹ Read at a meeting of the Practitioners' Society of New York, May 4, 1883.

unusually ready but weaker than normal. The anæmia has increased the nerve-irritability. The nerve prays for blood as Romberg has said. But if you diminish the nutrition of the nerve in any way, it will pray to have its food restored. The prayer comes readily but is short and weak. So it is with nerve-tissue anywhere in the body. Conceive the nervous system to be represented by a tuning-fork with strong, thick blades. When this is struck sharply it responds with a loud and long vibration. If now the blades are worn down till they are very thin, they respond to even a feebler blow, but the response is less vigorous and lasting. So it is with this or that part of the nervous system in functional nerve-enfeeblement.

2. The condition of absolute or almost complete weakness. Here the nervous centres are really exhausted. They respond not only more feebly but less readily, or perhaps not at all. Such a complete exhaustion rarely affects the whole system, but rather certain parts, certain neuro-mechanisms. Sexual impotence illustrates it; while sexual weakness illustrates the preceding phase of irritable weakness.

3. A condition of lessened resistance in the nerve-centres, so that impulses flow over from their natural channels. A slight stimulus causes a dozen reflexes instead of a single one (as we see illustrated in nervous individuals); or a simple sensation awakens a dozen active feelings (as in hysteria); impulses pass up from the viscera or from different parts of the body into consciousness, flowing beyond their natural channels, as in hypochondria; the patient seems to feel some of the functional acts of his intestines or his liver. This condition is necessarily present in over-irritable and unstable centres.

4. A condition in which higher and inhibitory centres are lessened in power. When general enfeeblement attacks the nervous centres it affects those higher and last evolved first. Yet these have important functions in keeping order and harmony among centres below. Reason, judgment, the power of making choice being weakened, the emotions are left more active and less controlled. Such a condition helps to increase the functional disorder in nerve-weakness.

Lest you think this "shelving-off" theory (though, of course, not original with me) a somewhat fantastical one, let me give an illustration to show that we do have controlling centres: Make a cross section of the medulla of a rabbit 3 ctm. above the point of the calamus scriptorius, and the spinal reflexes below will become disorderly and demoralized. Make the section 2 ctm. higher and the spinal reflexes continue normal and orderly; you have not, in the latter case, cut off from the spinal cord its controlling centre. It cannot be doubted that there are similar regulating centres in the human body.

Symptomatology.—The symptoms pertaining to nervousness, neurasthenia, hypochondriasis, hysteria, would fill pages.

In analyzing them, it appears to me very helpful if we look upon the body as a mass of physiological machinery, of which the nerves are the motive and regulating power. For the function of the nervous system is, in a word, to set free and to regulate the energies of the body. Regarding the living body, then, as a compound of many neuro-mechanisms, we can divide them up as follows:

1. Simple and compound muscular neuro-mechanisms.
2. Sensory mechanisms, general and special.
3. Vascular, secretory, and trophic neuro-mechanisms.
4. Neuro-mechanisms of vegetative life.
5. The psychical mechanisms.

It is, I believe, unwise and confusing to attempt to separate, physiologically or even clinically, the disturbances of the sympathetic from those of the cerebro-spinal system. They are anatomically and functionally closely united.

With the above as a basis, we may make the following analysis of the chronic functional disturbances of the nervous system:

1. Irritable or absolute weakness of the simple cranial and spinal muscular neuro-mechanisms: *e.g.*, twitchings.

2. Excessive, perverted or weakened activity of the compound muscular neuro-mechanisms: *e.g.*, contractions, convulsions, paralyses, muscular weakness.

3. Corresponding disturbances of the (*a*) general sensory mechanism: *e.g.*, hyperæsthesia, neuralgia, anæsthesia, spinal irritation; (*b*) of the special sensory mechanism: *e.g.*, disturbances of sight, hearing, etc.

4. Disturbances of the vascular mechanism: flushings, migraine, pupillary disturbance, anæmias and hyperæmias of organs.

5. Disturbances of the secretory and trophic mechanisms.

6. Disturbances of the neuro-mechanisms of vegetative life: *e.g.*, cardiac (palpitations); respiratory (sense of suffocation); gastric (dyspepsia, boulimia); intestinal (constipation, insufficient secretion, dyspepsia); hepatic; sexual.

These mechanisms are for the most part compounds of some of the others, hence their distinct separation is made largely on anatomical grounds.

7. Disturbances of the psychical mechanism: loss of co-ordinative power, inability to concentrate the mind or to use it continuously, morbid fears, emotional disturbances, impaired will-power, etc.

Classification.—It would be very fortunate if we could definitely assign the various forms of nerve-weakness to their proper category. This is not possible, however, since the different forms run into each other, and it is only the most pronounced cases which can be isolated and stamped as being of a particular class and no other. Neurasthenic persons are certainly nervous; hysterical persons often show plain evidences of a general nerve-enfeeblement; hypochondriacs may be also somewhat hysterical.

I venture, however, to lay down some distinctions:

Thus in ordinary *nervousness* there is simply an increased "irritability with weakness" of some or all of the nerve-mechanisms. The sensibilities are more acute, the reflexes more active. There may be some disturbance of the bodily functions, *e.g.*, dyspepsia, palpitations, neuralgias, insomnia. But these are not permanently localized, so that they in turn act reflexly and steadily increase the general trouble.¹

In that form of disease which has been described by Beard and others as *neurasthenia*, or nerve-enfeeblement proper, we have, in addition to various general nervous symptoms, special and quite permanent disturbances of function. The brain is decidedly enfeebled in some of its functions; the condition is so pronounced that doubtless vascular changes have ensued which react upon the disease to increase it. Or the stomach or sexual organs are crippled in the same manner.

A case is not one of *neurasthenia proper* unless the disease has specially localized itself upon some organ or neuro-mechanism to such extent that the local disturbance is a *locus morbi* reacting upon the general system. The distinction thus made is arbitrary, but a useful one, and I put it forth till a better is presented.

It follows, of course, that *hysteria* is only a neurasthenia. It is, however, markedly separated by the fact that it is much more, in its clinical aspect, a brain disease, a psychopathy, although the spinal cord becomes also involved. I also believe that all the phenomena can be explained on this view. Hysteria is characterized: 1, by the excessive irritability of the nerve-centres, culminating generally in convulsions; 2, by the extreme sensibility of the sexual reflexes; 3, by enfeeblement of the higher psychical powers, the result being excessive activity of the emotions; 4, by a morbid self-concentration upon the bodily sensations. By virtue of

¹ Many persons, especially Americans, are "nervous," but are yet in good health. In these there is an increased irritability or functional activity of the nerve-centres *without the weakness*. They are nervous but have not the disease "nervousness."

her peculiar psychical condition a hysteric is constantly throwing herself into semi-mesmeric states. Hysterical spasms, pains, paralyses, perversions of sense, are very analogous to those produced artificially in healthy persons susceptible of the hypnotic influence.

Hypochondriasis is still more pronouncedly a brain disease, though sometimes only a symptom of a general nerve-enfeeblement. Here we have also some of the features of hysteria—a morbid self-concentration, a morbid susceptibility to visceral impressions. But there is not the exaggerated irritability of hysteria, nor is there so great an enfeeblement of the higher psychical powers.

I present here the provisional classification above indicated:

I. *Nervousness*.—Characteristics: A general irritable weakness of brain, etc., cord, special neuro-mechanisms not seriously and chronically affected so as to react and increase the chronic trouble.

II. *Neurasthenia* (nerve-enfeeblement proper).—Characteristics: 1, irritable weakness of nerve-centres and mechanisms; 2, or absolute weakness; 3, a localization of the disease in various neuro-mechanisms, causing special (gastric, sexual, etc.) forms of neurasthenia, which react to keep up the disease. The phenomena of lessened resistance, of enfeebled controlling centres enter into the disease more or less.

III. *Hysteria* (a neurosis and psychosis combined, but more the latter).—Characteristics: 1, a "shelving-off" of higher controlling powers; 2, greatly increased irritability (with weakness) of lower centres, especially (a) emotional, (b) spinal reflex, culminating in *convulsions*; 3, localized disturbances of various neuro-mechanisms (motor, cardiac, gastric, sexual, etc.), these disturbances being more acute, more variable, more pronounced than in neurasthenia proper; 4, special irritability of nerve-centres to sexual stimuli.

IV. *Hypochondriasis*.—Characteristics: 1, special sensitiveness (i.e., increased irritability) of emotional and perceptive centres to visceral and sensory impressions (morbid self-concentration); 2, lessened resistance and overflow of visceral and sensory impulses.

The foregoing will I fear seem somewhat recondite. It may be asked: Is there any good in knowing when a hysterical woman comes into your office that her nerve-molecules are in a too explosive condition, and that the top-centres of her brain are functionally sliced off?

It appears wise to try and see as deeply as possible into the intimate nature of disease. Thus some of the practical conclusions from the previous analyses are that over-activity of a nervous system may signify weakness rather than strength; that such over-activity in one part may mean simply that another part is weakened, the check-reins dropped; that true hyperæmia does not characterize the nerve-centres in chronic forms of nervousness, neurasthenia, etc., since it is the correlative of increased functional power.

TREATMENT.

In discussing the subject of treatment I shall refer only to the treatment of the classes which I have described as the nervous, and the neurasthenic proper. It is intended not to go over the whole subject, but having outlined certain general principles to call attention to some special measures with which I have had experience.

General principles.—The points of attack in the treatment of the neuropathies under discussion are: 1, the general condition of health and general nutrition of the body; 2, the nutrition of the nervous system and the neuro-mechanisms specifically; 3, specific medication; 4, the treatment of local sources of irritation, cerebral, spinal, gastric, intestinal, genito-urinary, vascular (this may include surgical measures); 5, mental treatment.

It is an accepted principle in the general treatment of

most chronic neuropathic disorders that there should be two periods, one in which sedatives should be employed; in the other stimulants and tonics. A nerve made over-irritable by anæmia, can be quieted by giving a drug which directly lowers the irritability, steadying the unstable molecules, or, by enriching the blood and thus removing the irritant. It is found practically that often the sedatives and tonics can be given together.

Another most important principle in treatment, is the necessity for change of therapeutic method. No drug and no special measure should be kept up continuously. There should be intermissions from all treatment if possible, and the disease should be successively attacked by various remedial agents.

A third important factor is the treatment by measures diverted to the afferent nerves, calling into play the reflex inhibitory and other mechanisms.

I present here the various therapeutic measures to be employed in the treatment of nerve-weakness in its general and localized forms:

Hygiene.—Muscular exercise, massage, Swedish movements, climate-cure, moist and warm localities, sea-voyages, simple removal from ordinary surroundings. Mental hygiene: Amusements, change from ordinary tasks, the discipline of cures and special hospital establishments. Diet: Such as is best digested, slight excess of fats and nitrogenous food.

Internal medication.—Sedatives: Bromides, chloral, paraldehyde, hydrobromic acid, lupulin, camphor, scutellaria, cypripedia, digitalis, stigmata mais, valerian, gelsemium, conium, opium, cannabis indica, asafetida, hydrocyanic acid, ergot.

Tonics and stimulants: Phosphorus, strychnine, arsenic, zinc musk, cœnanthic ether, caffein, thein, coca, salicin, quinine, alcohol. The various aromatic and simple bitters, mineral tonics, iron, act indirectly as tonics. Nitrous oxide.

Surgical Measures.

External Medication.—Tonic: *Electricity*—general electrization, faradic, galvanic, static, special electrization of intestines, urethra, sexual organs, spinal cord, brain. Nerve-vibration.

Hydrotherapy.—Tonic: Cold douches over body or spine, cool to cold baths, plain or medicated; sea or river bathing; acid, aromatic, and sulphurous baths; baths with stimulating friction, and use of oils, aromatics (myrrh, rue, savine, rosemary).

Sedative: Turkish or Russian baths; warm baths, 80° to 95°; hot baths, 95° to 120°.

Revulsives and Inhibitors.—Blisters, seton, sparks of static electricity, hot iron, acupuncture, ignipuncture, aquapuncture; cold (ice-bags); heat. Moxæ.

Regarding the sedatives which may be used in nerve-enfeeblement.

The *bromides* here take the first rank. Every one is familiar with their value. Some statements about them, however, will bear repetition. They should be given generally in larger doses than is ordinarily done, viz. gr. xxx. to gr. xl. or 3 j. The physician should understand that bromization is often the thing needed, not simply giving bromides. Bromization will secure therapeutic results, when simply giving bromides is of no effect at all. A convenient test for bromization is in many cases the production of faucial anæsthesia, so that the finger or a pencil can be thrust into the back of the throat without provoking reflexes. The bromization need not be kept up long, but may need to be repeated. It has seemed to me beneficial to put a patient through a "storm" of bromides just as is done in epilepsy.

Much larger doses of bromide can be taken and the drug can be kept up longer by giving digitalis, or cod-liver oil and iron, or coca at the same time. One patient who was only comfortable when nearly bromidized, felt less depressed while chewing coca leaves. A frail and somewhat anæmic patient of mine takes gr. xl. of bromide three or four times a day with iron, oil, quinine,

and digitalis, and does not seem to suffer seriously from bromide depression.

The most powerful bromide is the lithium salt. But this is expensive and not always obtainable. Bromides are more powerful in combination, and one of the best combinations is, I think, that devised by Dr. Beard, and known as "Bromidi comp." The formula is as follows:

R. Brom. sodium,
Brom. potass.,
Brom. calc. āā gr. x.
Brom. lithiæ gr. v.
Iod. potass gr. ijss.
Fowler's solution gtt. ij.
Tr. capsici gtt. j.
Aqua q. s. ad ʒj.

M. Sig.—One dose.

Acne is to some extent prevented by drinking large quantities of water with each dose and by the addition of Fowler's solution.

If bromide of sodium be dissolved in carbonic acid water, ʒss. to a tumbler of the water, it makes a mixture very much like Saratoga Geyser, and New York ladies will drink it with much satisfaction. It is an improvement on the bromides with Vichy, as suggested by Dr. E. C. Seguin.

Hydrobromic acid.—For a year and a half I have been using hydrobromic acid quite extensively as a substitute for the bromides.

I find that it is a sedative like the bromides, that it does not produce acne nor constipation, nor does it often disturb the stomach. It may be substituted for the bromides in milder cases, even in treating epilepsy. It is convenient, because it can be given with iron, quinine, and other tonics. The objections to it are that in order to get powerful sedative effects one must give it in disagreeably large doses. The ordinary so-called Fothergill's solution has a strength of three per cent. of the pure acid, and it is altogether too weak to have much sedative effect. The doses which I usually employ are from ℥xl. to ʒij. of the ten per cent. solution. I have given ʒij. four times a day without causing any but sedative effects.

With some persons the bromides do not act well. They will even increase irritability and cause insomnia. For these a very efficient sedative is one suggested by Dr. Beard,¹ of which the formula is as follows:

R. Fluid extract scullcap,
Fluid extract cypripedii,
Fluid extract blue cohosh,
Fluid extract lupulin āā ʒj.
Fluid extract cannab. ind. ʒjss.

Sig.—One drachm dose. The cannabis indica can be omitted.

The value of *ergot* is well known. It sometimes increases the sedative action of the bromides, especially when there is venous hyperæmia at the bottom of the trouble. In the insomnia occurring in certain cases of hypochondria, hysteria, and melancholia, and in congestive headaches, it acts when even chloral and bromides fail.

Yet on the whole, ergot has not a very wide range of usefulness in chronic nerve-weakness, and its value, given alone, according to my experience, is not great.

Caffein is not generally considered a sedative, but in the first homœopathic dilution I have known it to relieve an obstinate case of insomnia with bad dreams. In other cases it has failed.

Paraldehyde is a new hypnotic recently introduced by Cerverlo, and tested in numerous cases by Morselli. It is claimed to be an excellent and safe hypnotic, acting like chloral upon the brain, but rather stimulating the heart. It seems to be a good hypnotic, perhaps not so

powerful as chloral, except in disagreeably large doses. In two cases it appeared to have a general sedative and anodyne effect. A nervous, hysterical woman, who had been taking it, said she had not felt so well for a long time. The dose is from ʒss. to ʒij.

Hyoscyamia is not a very trustworthy drug, and need rarely be resorted to in the nervous troubles of the kind under consideration.

The oleate of aconitia and aconitia internally, but especially the former, are often very useful in relieving some of the neuralgic pains. Nothing special need be said about the other sedatives, chloral, cannabis indica, etc.

Tonics and stimulants.—Of the tonics and stimulants to the general system I have nothing especial to say. One of the best of the bitter tonics is salicin in rather large doses. A formula which is not particularly original is the following:

R. Acid. hydrobromic. dil., 10% or 3%,
Tinct. ferri muriat.,
Acid. phosphor. dil. āā ʒj.
Strychniæ sulph. gr. ʒ
Salicin ʒjss.

Sig.—One drachm t.i.d.

The drugs which especially affect the nutrition of the nervous system are the following:

Arsenic.—In cases where the nervous troubles are kept up by a prostatic or urethral irritation the following formula was used by Dr. Beard:

R. Liquor potas. arsenit. ℥ v.
Tinct. cantharid. ℥ ʒ.
Tinct. hydrastis ℥ x.
Tinct. nuc. vomic. ℥ x.
Tinct. cannabis indica ℥ x.
Aque q. s. ad ʒj.

Sig.—A teaspoonful.

I have had prepared and used in several cases the liquor brom. arsenic. of Dr. Theo. Clemens, but have not been able to get any good results from it.

Zinc.—This may be given in a formula which includes a number of the zinc salts, as follows:

R. Zinci bromid.,
Zinci valerianat.,
Zinci lactate. āā gr. j.
Zinci phosphid. gr. ʒ.
Extr. belladon.,
Extr. nucis vomic. āā gr. ʒ.
Ft. one capsule.

The belladonna and nux vomica may be added or left off in accordance with the indications.

This combination is, I think, more efficacious than the single salt, yet I cannot say that I have used it often enough to speak dogmatically regarding it.

Coca is a very useful medicine if a good quality can only be got. It temporarily brightens up a patient. It is only palliative however. Dr. Beard several times told me that it had greatly disappointed him.

Caffein, in my experience, has not been of much service as a nerve-stimulant.

Damiana I have been disappointed in. Dr. Beard told me he had found it of about as much value as so much water. Possibly samples differ. *Celerma*, in my opinion, is a humbug.

In the treatment of old-standing nervous disorders of the class in question, I have learnt that there is little to be expected from nerve-tonics. Only rarely is our work brightened by a meteoric success apparently due to these medicines alone, except the cases where there is anæmia or chlorosis, and where large doses of iron often act remarkably well.

External medication.—*Static electricity* has markedly helped cases of hypochondria, hysteria, and general nerve-weakness. It is not so useful, however, as other forms

¹ During the summers of 1881 and 1882 I took charge of Dr. Beard's practice during his absence in Europe. He kindly gave me access to his private formulae, and described some of his special therapeutic methods. Hence my frequent reference to them now.

of electricity in most cases of nervousness and neurasthenia proper.

General electrization by the faradic and galvanic currents, it is well known, acts as a tonic to the nervous system and to the general nutrition of the body. My experience is that this electrization ought to be given oftener than is usually done, *e.g.*, every day or even two or three times a day. This is the view also of many German electro-therapeutists. It is known that electricity by improving the nutrition allays irritability and acts as a sedative. But I think it is demonstrated that by the "polar method" and by special electrodes we can undoubtedly get specific sedative effects on the brain and cord at each application.

In cases of unilateral chorea I have in numerous instances applied a large stable anodal electrode to the scalp over the region of the motor convolutions, the cathode is held in the hand of the opposite and affected side. A current of two to eight Stoecher's cells has been allowed to pass for about five minutes. In this way I have produced distinct amelioration in the choreic movements lasting for about twenty-four hours.

I have not had an opportunity of using anodal galvanism of the brain alone in cases of mental irritability and weakness, but others have done so, and Althaus especially recommends the measure most enthusiastically.

In some forms of very severe chronic headache, strong anodal galvanization with the foot on the cathode will, I believe, prove beneficial.

I have had made a special electrode by which I can get the anodal effects upon the spinal cord. The spinal electrode is a long narrow sheet of brass, tempered so that its shape can be changed. This is covered with sponge. It is placed over the spine, covering the whole length, and the indifferent electrode held in the patient's hands. Before turning on the current the superficial or skin reflexes of the thorax are tested; then a strong current of twenty-five or thirty cells is passed, and the reflexes tried again. If the irritability of the spinal cord is really reduced by the anode, the reflexes which are purely spinal would be less easily elicited. This has proved to be the case in some cases but not in others.

We have, I think, in electricity, an agent by which direct sedation of the over-irritable nerve-centres can be obtained. In a case of irritable sexual weakness with premature emissions, the patient after a few applications of my spinal electrode was greatly improved, though electricity had been tried before for a long time in vain.

I have here a special appliance for the treatment of sexual nerve-weakness. It was devised by Clemens, of Frankford, and was used upon a most obstinate case of impotence, a case which had been in the hands of many prominent neurologists in New York. The patient rapidly recovered and is now a new man. This which I know to be a fact is my excuse for showing the apparatus, which apparently has a good deal of hocus-pocus about it.

It consists of a zinc cylinder made to enclose the penis, with a funnel attached so that it can be filled with Rhine wine or weak alcohol. The positive pole is connected with it, and the negative pole, which is attached to a very large electrode, is placed over the spine. It is to be used three times a day for five or six minutes, a current of five to eight cells being employed. It is supplemented with a set of magnetic apparatus which seems to be of subsidiary importance. There is no doubt that the patient gets the sedative effects of the galvanic current very thoroughly. I am at present treating a case with it. The patient, who is a very intelligent man, in fact a doctor himself, was very decidedly improved, and is indeed now almost well.

Hydrotherapy.—As a *stimulant and tonic* we administer general cool and cold baths, medicated or otherwise; general tepid baths, gradually making them cooler; local baths of various kinds; cool and cold douches, hot douches or jets, and alternately hot and cold douches or jets; baths with massage or electricity.

Cold baths increase the oxidation of tissue and thereby act as a stimulus to nutrition. They increase the flow of urine. Reflexly they may relieve congestions and inhibit pains. Cold baths act as a tonic to irritable weak nerve-centres by thus relieving congestion, improving nutrition. Cold baths are invaluable to the nervous and neurasthenic when the general system is strong enough to react.

In sexual neurasthenia, with emissions, where the irritability is more prominent than the actual loss of power, cold sitz baths once or twice a day, or cold douches are indicated.

Cold douches to the back are of help to cerebral asthenia, with insomnia, morbid fears, hypochondriasis. Persons who cannot endure cold baths at first can be made to do so by beginning with tepid or cool water, and gradually lowering the temperature. Medicating the baths with salt and alcohol, or aromatics, adds to their effect.

Warm baths.—These also may be local or general. Warm baths relax the blood-vessels, weaken the heart-beat, increase diaphoresis, lessen the amount of urine passed, act sedatively upon the nervous system. The sedation is that of exhaustion, however. Warm baths are to be used temporarily and intermittently, therefore.

I have known warm baths at night to help greatly in relieving insomnia. I have not known much benefit to come from Russian or Turkish baths.

Electrical baths furnish a good way to apply electrization. They are not in high repute among electro-therapeutists. In my very limited experience they have acted well.

Revulsives and inhibitants.—Of these, the cautery applied at the back of the neck and along the spine often gives excellent results in cerebral or sexual nerve-weakness. It stands at the head of counter-irritants.

After the cautery come blisters. Large blisters spread thin or in spots, so that they keep up a slight vesication for a long time, are one of the best forms.

Of the value of acupuncture, ignipuncture, the electric brush or moxa, the seton, I have nothing to say. If there is reason to suspect cerebral or spinal venous hyperæmia, counter-irritants ought to be freely used.

They are often also very potent in arousing dormant or enfeebled centres, or dispelling unpleasant symptoms, acting perhaps by reflex inhibition; I have, therefore, referred to them as "inhibitants."

Dry cups.—A patient of Dr. Beard's, who suffered from a most exaggerated anthropophobia, was treated for some time with little success. He went home finally, and being a mechanic, made himself a kind of air-pump with large cups attached. These he applied upon himself daily and with the result of becoming almost well. Dr. Beard had one of these appliances made and had used it considerably. At the time of his death he had an article prepared giving his results. It had helped a number of cases, but by no means all. A patient of my own—a neurasthenic with hypochondriacal symptoms—dated his steady improvement from a systematic cupping which I gave him.

Massage.—Massage alone does not give much success. It is a luxury in therapeutics. Some neurasthenics cannot endure it. The *masseur*, if experienced, can tell after a few trials whether he can help the patient.

The *Weir-Mitchell treatment* by isolation, rest, massage, electricity, and overfeeding, is oftener applicable to women than men. The majority of male neurasthenics are, I think, not benefited by it, or, at least, will not submit to it. I believe that its good results are chiefly from the psychical effects of a rigid system of eating and living.

Diet.—Dr. Beard, just previous to his death, had been studying the subject of food, and had written a chapter upon the philosophy of diet, based on the principles of evolution. In it he announced the following very original views:

"First, living beings feed on that which is below them in the scale of development.

"Second, the best food for man is that which is just below him or nearest to him in the scale of development.

"Third, food is difficult of assimilation for man in proportion to its distance below man in the scale of development."

The following propositions he also announced as verifiable: "First, the earth feeds on gases; fruits and cereals feed on the earth; the lower animals feed on fruits and cereals, and on other animals; man, therefore, should feed mainly on the lower animals, with a small proportion of fruits and cereals. Second, in proportion as man grows sensitive through civilization or through disease he should diminish the quantity of cereals and fruits and increase the quantity of animal food."

According to this theory and the doctrine of evolution the best food for nervous invalids would be as follows: beef, mutton and lamb, fowl, eggs, milk, fish, butter, wheaten bread.

In discussing the above theory Dr. Beard brings evidence to show that monkeys are good eating, that man is good food for man, and that cannibals are the strongest and healthiest of savages!

Without discussing this subject now, it has been generally admitted that a nitrogenous diet is best for those of unstable nervous energy. We can explain this from the fact that nitrogenous food has more to do with structure and nutrition, non-nitrogenous with function, or discharge of energy. In the nervous we want a food that will give more stability to cell and axis-cylinder, and not a food which feeds the function and really increases instability. To return to an old simile, the nervous system may be compared to a delicately vibrating rod fastened at one end. Normally, vibrations take place without waste of the metal of the rod, or of the tissue of the nerve. In the case of this latter, however, over-vibration, too persistent vibration, and other causes finally wear away its textures. It becomes, so to speak, thinner, weaker, yet it vibrates more readily and delicately, just as does the rod when made thin.

The object of radical curative treatment is to make the nerve more, so to speak, solid. Nitrogenous food supplies tissue to the wasted nerve, and thus helps to do this. Fatty food is also essential, because fat also is a constituent of nerve-tissue, and a help to nerve-action.

I believe, however, that too much stress may be put upon special diets, and that after all a mixed diet of thoroughly digestible and palatable food is often quite as good as a special diet, unless some special gastric or intestinal trouble be present. The nervous system is not the only thing that has to be dieted.

Mental therapeutics.—I am profoundly convinced of the prominent place of mental influence in the therapeutics of functional nervous diseases. "The most powerful single remedy that can be used in the treatment of neurasthenia is the mind," was an aphorism of the late Dr. Beard, and all experience acknowledges its truth. Witness the success of faith-cures. I have seen a hypnotic fall very nearly lifeless when told to shoot himself with a stick which he thought was a loaded pistol. This mental therapeutics is the mainstay of charlatanry and the backbone of many a genuine professional success. Some persons are spoken of as born physicians, and I conceive it is because they have the tact and skill to manipulate the *psyche* of their patients. Such skill is particularly needed in treating chronic functional troubles. "It is not everybody," says Holmes, in describing Dr. Kittridge, "that enters into the soul of Mozart's or Beethoven's harmonies; and there are vital symphonies in B flat and other low, sad keys which a doctor may know as little of as a hurdy-gurdy player of the essence of those divine musical mysteries." One must get a mental grip upon the patient, and if the patient is intractable he had better have a change of environment.

It will not do in treating the undervitalized neurotic

to scoff at his troubles, or to try and "bulldoze" his symptoms. He must be persuaded that you understand his case, appreciate the reality of his suffering, and made to feel that you can help and perhaps cure him.

The application of remedies must be made also, so that some psychical stimulus, if possible, shall be mingled with their administration. It is not an easy thing to touch the stops and strings of an enfeebled nervous system so as finally to evoke harmonies. He who succeeds is more than a specialist, he is a true physician.

DISTURBANCES OF THE SEXUAL ORGANS IN THEIR RELATION TO AFFECTIONS OF THE EYE.¹

By HENRY S. OPPENHEIMER, M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE BELLEVUE HOSPITAL (OUTDOOR DEPARTMENT), ETC., NEW YORK.

It has been said that every specialist exaggerates the importance of the diseases coming under his own observation and treatment. Doubtless many reasons could be advanced why this should be true. To one who had not thought over the subject of this paper, or had had little experience with the disturbances of which it treats, it could well seem rather far-fetched to trace connection between the sexual and the visual apparatus or their affections. I hope, however, to convince any skeptic on the subject that there is more than simple coincidence in the occurrence of such, and I expect to show that almost every tissue of the eye is at times subject to change produced by certain conditions of the sexual organs; from the superficial and transient coloring of the skin of the eyelids during the menstrual period of many women, to disturbances of circulation in the retina and optic nerve of so serious a nature as to produce complete blindness. The study of the subject is connected with some difficulty, and this will explain the limited literature of the subject, as compared with its importance. Patients' statements (always to be taken *cum grano*) are particularly unreliable in this class of cases. It is not easy, and far from pleasant, to ask a girl, or woman, who comes for trouble of the eyes, about the condition of her sexual organs. Even with men the seeker after truths of this description is apt to be treated as inquisitive. The patient cannot see the use of the inquiry, and is apt to avoid a doctor who asks such irrelevant questions. In all disorders of the sexual system women are much oftener sufferers than men. The functions of menstruation, gestation, and lactation in the normal, healthy woman are of such magnitude and importance in her life, as compared with the sexual functions of the man, that naturally, due to the normal and abnormal, physiological and pathological changes in these functions and organs, the female sex furnishes a much larger number of the cases to be treated of here than the male. In the statistics prepared by Dr. Ludowigs² there were, out of 5,507 eye patients treated at Dr. Mooren's clinic in Düsseldorf, in 1880, of spontaneous troubles of the eye coming on after the years of puberty, 67½ per cent. women to 32½ per cent. men. There were naturally excluded from this calculation all cases of traumatism, of which men were the most frequent victims, and also all syphilitic affections. This percentage, however, is general. In certain affections of the eye there is a much greater preponderance of women. Of Basedow's disease there were 2 women to 0 men; episcleritis, 9 to 2; deep keratitis, 20 to 5; punctate keratitis and iritis serosa, 7 to 0; myodesopsia, 21 to 8; vitreous opacities, 12 to 4; hyperemia of nerve or retina, with hyperemia of the meninges or irregular menses, 36 to 7; amblyopia and metrorrhagia, 5 to 0; asthenopia from anemia, 40 to 5.

By these figures we see women in the proportion of from two to eight to one man. Eye affections can be produced either by reflex, nervous irritation, started in some

¹ Read before the East River Medical Association, May 9, 1883.

² Arch. of Ophthal., vol. xi., No. 3.

part of the sexual organism, or by changes in the circulation; or by both in the same individual. Irritation of certain kinds in one part of the nervous system can produce reflex disturbances of various kinds in the most distant part of the organism. Given an irritation of an afferent nerve, no one can tell where the reflex symptoms shall show themselves. A man steps onto a rusty nail, which produces the slightest punctured wound of the foot. In consequence of this injury he shall have tonic contractions of his risorius, masseter, and temporal muscles, and clonic spasms of different muscles of the trunk and limbs, joined to such exquisite hyperæsthesia of nerves of ordinary and special sensibility that a draught or a noise shall bring on a convulsion. This picture is familiar enough to us under the name of tetanus, and prepares us a little more for this statement: From irritation of the genital apparatus you can have spasm of the orbicularis muscle (blepharospasm), spasm or paresis of almost any muscle of the eye proper, affections of the conjunctiva, of the cornea, of the sclera, of the iris (mydriasis), of the ciliary muscle, of the choroid and vitreous, of the retina, of the optic nerve, and of the brain. Of this last, however, I mean to speak only incidentally, as it may be necessary to illustrate my subject. Of changes in the circulation I will speak later.

Spasm of the orbicularis muscle (blepharospasm) has been attributed of late, by most authors, to reflex origin. As early as 1810 Faurel (Sedillot's *Journal Gen. de Med.*) notices spasm of the lids so often accompanying chorea. He claims that all his choreic patients were onanists. Wendt (in his book on "Kinderkrankheiten," 1835) holds the same opinion. Michael (*Graefe-Saemisch*, vol. iv.), speaking of the etiology of these clonic spasms, says: "Increased predisposition is created by excesses in *venere et Baccho*, strong excitement." Ziemssen¹ thinks the statements of these patients too unreliable to found a positive opinion as to the cause of chorea thereon. Hermann Cohen (*Archives of Ophthal.*, vol. xi., No. 4) says: "I find so frequently the note in my journal, 'Confesses excessive onanism,' in cases of chronic blepharospasm (9-12 per 1,000 in 30,000 patients) that I cannot deny the probability of the connection between the spasms and onanism." There are cases on record in which the spasm occurred only when the patient attempted to speak and was spoken to.

Diseases of the conjunctiva, usually of a most stubborn kind, are not uncommon from these causes. Förster (*Graefe-Saemisch*, vol. vii.) mentions having seen a number of such in confessed onanists, from twelve to twenty years of age. They were mainly catarrhal and trachomatous inflammations with persistent hyperæmia. In this connection he calls attention to the intractable cases of pharyngeal catarrh, so often met in patients with spermatorrhœa.

H. Cohen (loc. cit.) gives six such cases, one of which had been treated for five years by himself and others with applications of copper sulphate and other astringents. Two of these patients were commercial travellers, who noticed in the morning, after having committed sexual excesses, great redness of the margin of the lids and of the conjunctiva. I have myself seen two similar cases in young men about town. I thought, however, that in their cases the loss of sleep and consumption of champagne was sufficient to explain the conjunctivitis.

Inflammations of the cornea are very much influenced by changes in the sexual organs. Parenchymatous keratitis shows itself more frequently at puberty than at any other period of life. Mooren² relates the case of a woman, twenty-eight years of age, who had never menstruated. She had a parenchymatous keratitis since she was fifteen years of age, much aggravated every four weeks. By strong emmenagogues an insignificant menstruation was induced a few times in succession, and "she was freed of her pain and photophobia as if by

magic." I can recall the case of a French-Canadian girl, twenty years of age, under my care at the New York Eye Infirmary during my resident surgeonship there, who had a keratitis and still showed extensive posterior synechiæ (I believe she was in Dr. Derby's division). She had violent exacerbations of her trouble at each period. I had overlooked the cause at the first exacerbation, but had my attention called to it by the nurse, who saw me puzzling over it. I may say that I observed this connection closely afterward, and in order to economize time and avoid tiring you with details I can give it as my experience that there is hardly any disease of the eye, or a wound after any operation in menstruating women which I have not seen influenced, more or less, during the monthly flow; or rather just before the beginning of the flow. I have seen wounds take on such alarming inflammatory action during this period that I am very careful now to ascertain the time when this is expected before operating. I would not operate for cataract at such a time as to have the catamenia appear during the healing process; unless there were some special reason for urgency.

Mooren³ tells the case of a woman, forty-five years of age, who had a retroflexion with a tumor of the cervix uteri. When she began being treated for this her right eye became affected with an episcleritis. Every touch of the cervix and every insertion of a pessary aggravated the episcleritis. This was cured and remained so for a year. Then fresh uterine trouble brought on an episcleritis in the *left* eye, which grew worse on each local application to the uterus. I have observed a vigorous German woman, of about the same age, who had a mimic spasm of the right side of her face for years. This was complicated at times by trifacial neuralgia and a sclero-keratitis of the same side. This woman volunteered to me the statement that she had noticed severe exacerbations of the pain and eye trouble during her periods. (I presented her at that time to the Ophthalmological Society.) When I lost sight of her her spasms and eye trouble had been relieved very much, but not completely, by antirheumatic remedies and massage.

The iris is never, so far as I know, inflamed by reflex irritation. In septic or puerperal metastatic attacks, however, it is usually implicated in the purulent inflammation; which has, as a rule, its beginning in the ureal tract and extends commonly to every tissue of the eyeball and even to the cellular tissue of the orbit. There are cases, however, of such irritation in which the muscular structure of the iris is affected, either by paresis or spasm. I refer to the cases on record of mydriasis (dilatation of the pupil) which is due either to irritation of the sympathetic nerve, or to paresis of the twig supplying the iris from the oculomotorius. These cases may be uni- or bilateral. Parametritis, of which I shall speak later if the time permit, endometritis, retroflexion, and hyperæsthesia with scanty menstruation are among the causes given. While interne in Charity Hospital I treated a young woman for granular vaginitis. The pupil of her left eye dilated at times without evident cause. She had no trace of brain trouble, goitre, or aneurism, for which I examined her carefully.

Her vision was not affected at the time. I examined the eye by the ophthalmoscope; but I do not think that my experience with the instrument was sufficient *then* to make my opinion reliable. I *thought* the fundus was normal. The connection between the vaginitis and the mydriasis did not occur to me at that time. Mooren² saw one case of myosis (contraction of the pupil) in a woman, sixty-eight years of age, whose uterus had been prolapsed for years, without paralysis of the legs or bladder. She had also a slight atrophy of the optic nerve.

The ciliary muscle may be partially or completely paralyzed by irritation of the genital organs. Miss N—, ³ twenty-four years of age, practised onanism since she was

¹ Handbuch, vol. xii., 2.² Arch. of Ophthal., vol. xi., No. 3.³ Ibid.² Loc. cit.³ From Mooren, loc. cit.

fifteen years of age. Her power of accommodation has decreased from year to year. Her labia minora were unusually large, her clitoris was prominent and so excitable that amputation was advised.

A South American woman who had masturbated since her early youth had complete loss of accommodation. In both of these cases the genitals were so excitable as to give rise to great dyspnoea at times. A single woman, thirty years of age, had the same symptoms produced by intense irritation of the mucous membrane of the vulva from acne pustules and the constant scratching provoked by them. Pregnancy and lactation are held by several authors to be the cause of accommodative asthenopia. Hutchison ("Oph. Hosp. Rep.," vol. vii.) thinks it not infrequent.

The *vitreous humor* is usually affected in connection with diseases of the choroid or retina, so I shall speak of it only in connection with these tissues.

Hyperæsthesia of the retina has been observed very often in cases of parametritis. In the three cases just mentioned with deficient accommodative power this hyperæsthesia was very marked. The South American woman could hardly bear the lustre of the eyes of other persons. A fourth, a French woman, could hardly enter an illuminated room. After the cauterization of one of these sensitive, papillary swellings she had at the mouth of her urethra, and the use of bromide for some time, her eye troubles disappeared. In another woman a rupture of the perineum and descent of the uterus seems to have been the cause of hyperæsthesia and *spasm* of accommodation. She had four children, and the birth of each seems to have aggravated the condition of the perineum and eyes. A girl, twenty-one years of age, with infantile uterus was a victim of this same trouble. Mooren says¹ it is most often met with in congenital stenosis of the orifice of the uterus and can be caused by inflammation producing alteration in the shape or dimensions in any part of the genital tract.

From retinal hyperæsthesia we come naturally to *photopsia*, which may be, at times, only an increase of the same irritation. H. Cohen² records seven cases, four men and three girls, addicted to onanism. All were between the ages of fifteen and thirty-one. Each one of these gave a history of subjective perceptions of light, such as the sensation of dazzling by some bright moving figure, as a window, for instance, or bright rings, or dots, or stars, or snowflakes. In all these cases the eyes were in other respects normal, all having $V=1$, or over. In all but two both eyes were affected, and the dazzling vanished when the eyes were closed. Most of them complained of neurasthenia, insomnia, and pollutions.

Strictly speaking this need not necessarily be a retinal trouble. An irritation of any part of the fibres of the optic nerve will produce these subjective symptoms. This point of irritation may be anywhere from their peripheral expansion in the retina, along the optic tracts, the ganglia, the cortex of the occipital lobe, the cerebellum, or the olivary body in the medulla, to all of which points fibres have been traced by recent investigators. Therefore, unless other symptoms (herdsymptome) will indicate it, it is always impossible to say exactly where the point of irritation exists. I will not mention here retinitis as due to pregnancy, because usually albuminuria exists in these cases. We are certain, however, that pregnancy predisposes to both these troubles and I have no doubt every one present has seen them.

Two very interesting cases of retinal detachment (Mooren) will end my remarks on retinal troubles. In the first, a few years after marriage the introduction of a speculum, for the removal of some prominent Nabothian follicles, produced violent pain in the back and legs and obscuration of sight. Later, injections of warm salt-water produced inability to move the legs, ice-cold ex-

trémities from the hip down, objectively as well as subjectively, while the upper part of the body was very hot. She was often absolutely blind for a few minutes at a time. A large detachment of the retina was observed, and seemed to be the result. The patient had, however, before this time sclerochoroiditis posterior in one eye and exudation in the other choroid. The second patient, unmarried, had always had scanty and painful menstruation. General health good. In her right eye she had an anæsthetic retina with reduced vision and field, and a rosy injection around the papilla. The left eye showed atrophy of the optic nerve and partial detachment of the retina.

In the *choroid* we have a condition of chronic inflammation, which seems to be caused by uterine disorders. This has been denied. I have now under observation a dispensary patient with this choroidal picture, who has a chronic metritis. I can find no other apparent cause for her choroiditis. A second patient, a lady at the climacteric, who is myopic $\frac{1}{2}$, has aggravated choroiditis and vitreous opacities since her menses began to be irregular.

Now as regards the *optic nerve*, we have on record all grades of changes which seem to be produced, either by reflex irritation, or vascular changes in the uterus or ovaries. These can show themselves functionally in all degrees, from the slight narrowing of the field, or the least reduction of vision or color sense by weak illuminations, to the fulminating attacks of blindness by the sudden cessation of the menses, or a phlebitis of the central retinal vein.

Samelsohn (*Berl. Klin. Wochenschrift*, 1875) tells of a woman, twenty-one years of age, whose standing in the water with bare feet caused a sudden menostasis. She complained of an unpleasant pressure behind the eyes the same evening. Within the month she was completely blind. Samelsohn thinks it was a transudation into the orbit compressing the optic nerve. The ophthalmoscope showed engorged veins. The woman's sight returned in a week. Congestion of the optic nerve in cases of chronic uterine trouble has been observed very often. These may terminate in recovery, or atrophy of the nerve.

Since Rokitsky has made his contribution to the study of chronic congestion, it is easy to understand how a chronic hyperæmia can cause an atrophy. He describes a condition which he insists is the result of hyperæmia and not of inflammation. It is a deposit of new, gelatinous, connective tissue; which in time becomes fibrillated, then contracts, and becomes cicatricial, destroying the nerve-tissue in the course of this contraction. This process he has observed in the brain and in the spinal, olfactory, and optic nerves. If, as we have seen, the physiological flux can produce such changes in a woman's eye, it must follow that any of the chronic engorgements of the pelvic tissues and sinuses is certainly capable of producing a chronic congestion of the optic nerve. Displacement and flexions of the uterus, chronic engorgement of this organ, and the extensive venous network filling the pelvis, from inflammations or what not, can thus become causes of eye-troubles. Let us look for a moment at the venous connection between the parts. We have the spinal veins, carrying four longitudinal columns of blood the whole length of the spinal canal, from the foramen magnum to the coccyx. These veins ramify and communicate in all directions. They have no valves. They connect with the uterine and pampiniform plexuses and the ovarian veins through the lumbar and sacral veins. At its upper end this column of blood is joined to the vertebral and inferior cerebellar veins, and the occipital and petrosal sinuses.

Thus we see that the cerebral, the spinal, and the pelvic venous system of a woman is practically continuous. Hence, we have the almost universal backaches and headaches in woman, with the most trifling menstrual disorders, and, in fact, in those whose catamenia are nor-

¹ Loc. cit.² Loc. cit.

mal, as far as we can tell. We know that both the origin and the course of the optic-nerve is in great part superficial, and therefore easily accessible to disturbances from irregular circulation in the meninges. Many facts of the clinical picture have been given, although necessarily short and imperfectly.

Lastly, I desire to call your attention for a moment to the fact that Graves' disease (exophthalmic goitre) has been considered by some authorities as having its origin through reflex action in disturbances of the sexual system.

We know that women are much more subject to the disorder than men: Emmert counts one man in ten, Von Graefe makes it one in seven, Mooren one in thirteen, Geigel one in seven, Von Dusch about one in five (11 in 57.5).¹

The only writer who has these proportions reversed, so far as I have looked, is Chvostek, an Austrian army surgeon. He naturally saw more men than women. If I make a grand average of all these it gives us about one man to eight women. Laycock calls attention to the fact that old women (after the menopause) never have Basedow's disease. Other arguments are that frequently the thyroid gland enlarges in girls at the time of puberty. H. Cohen (loc. cit.) has recorded one such case in which a regularly recurring exophthalmos during the menstrual period was verified by measurements.

These facts warrant us in concluding that Basedow's disease is influenced by sex and some changes and disturbances of the sexual organs. Freund, who has made an exhaustive study of some of these diseases states that in the last ten or twelve years he has not examined a single case of morbus Basedowi in women without finding a parametritis in the contracting stage. Förster (loc. cit.) gives an account of one case which seems to show that the female sex does not exclusively show this disease in consequence of sexual excitement. The case is so extraordinary a one that I thought it would be interesting to give it here translated in full. "In July, 1866, I saw a clerk, twenty-four years of age, with exquisite morbus Basedowi. Pulse 120, strong cardiac impulse, moderate swelling of the thyroid gland, with pulsation in it, and considerable protrusion of both eyeballs. The last symptoms brought him to me. The symptoms dated back three weeks, and appeared suddenly. He gave the following history: 'About the middle of June he struggled for about half an hour with a girl in the effort to have connection; but her energetic resistance prevented the consummation. He so overexerted himself with this effort that he finally felt very faint and had to take several glasses of Madeira to restore him partially. The violent heart action which began during the struggle has continued since. Two days later he first noticed the prominence of his eyes, which has steadily increased since then.' Both epididymes were painful and swollen. Professor Freund, who also examined the patient, corroborates this. Quinine, in large doses, was ordered and moderation in the exercise of the sexual function advised. The patient departed and presented himself again nine months later. He stated that the exophthalmos and violent heart action had gradually subsided after taking about 9.00 of quinine. However, in October (four months after the first appearance), the former, and in December (six months), the latter symptom had begun to show itself again. I found in April, 1867, essentially the same condition as in July, the exophthalmos even increased. The patient looked well, felt strong, and had retained a good appetite. No sign of anemia had developed. The inquiry into his sexual behavior was evidently disagreeable to him. He went off and I have not seen him again."

Finally, gentlemen, I should have liked to say something about a most troublesome class of cases, which are the terror of ophthalmologists. If I were to undertake

to tell you a tenth of all the symptoms of which they complain, I should have to detain you too long. The most careful examination rarely shows objective basis for the violence of the symptoms complained of. Phobias, pain on using the eyes, pains in various parts of the eyes and orbit, changing in character, but always of the most hyperbolic severity, inability to wear their glasses, etc., are at the bottom of the long tale of woe. These pains are never so severe as to prevent attendance at the theatre or ball and rarely intrude themselves when there is pleasant company in the house. The name of the disorder is kopiopia hysterica. For fear it should prejudice you against the female sex I will read you a case from Förster (loc. cit.) in your own sex. "A married man, thirty-seven years of age, with a long list of the most pronounced symptoms and no lesion to explain them, admitted that his sexual capacity had very much decreased. Coitus barely once a month, never a firm erection, immissio penis always problematical, ejaculation usually took place without it. The man had strikingly small testes and a thin, milky discharge from the urethra." Förster says that this case is not single, only that the patients' statements are usually unreliable on the subject. He suggests that one obtains more reliable data from their wives, who seem more carefully to note the difference between the past and the present. Kopiopia hysterica in women is almost always connected with a lesion in the pelvis; which Prof. Freund, who first noticed it, and who gives a most interesting clinical and pathological picture of it in his publications, calls "parametritis chronica atrophicans." I can do no better than to close with a quotation from Mooren: "According to my own experience," says he, "I would say that of all the eye affections of choroid, retina, optic nerve, etc., there are none which are not influenced either by the normal or pathological workings of the uterus."

189 SECOND AVENUE, NEW YORK.

AN ERYTHEMATOUS ERUPTION FROM CHLORATE OF POTASSIUM.

By HENRY W. STELWAGON, M.D.,

PHYSICIAN TO THE PHILADELPHIA DISPENSARY FOR SKIN DISEASES, ETC., PHILADELPHIA, PA.

THE subject of "medicinal eruptions" has received considerable attention during the past few years, and at the hands of several writers has been exhaustively presented.¹ The excuse, therefore, of reporting fresh examples must lie either in the fact that the observation is one respecting a drug heretofore unsuspected, or that the eruption is characterized by unusual features. So far as I can ascertain, the chlorate of potassium has not been recorded as capable of causing cutaneous disturbance, and the former reason, therefore, is answerable for this communication. The patient—a male—in whom the eruption was observed was suffering from secondary syphilis, and had been under treatment for several months. The symptoms of the disease were of a mild type, and treatment had consisted in the administration of small doses of the corrosive chloride of mercury. About this time a few mucous patches showed themselves in the mouth. The stick of nitrate of silver was used, and tablets of potassium chlorate ordered, several daily; these were to be allowed to dissolve in the mouth slowly. Four days later the gentleman returned, much annoyed and worried concerning a fiery erythematous and papular eruption, which had made its appearance over the trunk and neck, especially well marked on the upper part of the back. There were no subjective symptoms. The eruption was similar in character to that of erythema multiforme, and of this nature I was inclined to

¹ Behrend: Zur Allg. Diagnostik der Arznei Ausschläge; Berlin, klin. Wochs., p. 714, vol. xvi., 1879. Morrow: On Drug Exanthemata; N. Y. Med. Jour., p. 224, vol. xxxi., 1880. Van Harlingen: Medicinal Eruptions; Arch. Derm., p. 337, October, 1880.

¹ Sattler in Graefe-Saemisch, vol. vi;

consider it. The possibility of its being due to the mercury was entertained, but as this had been taken off and on for several months without any such result before, and as, moreover, the dose had been very small, the idea was dismissed. At this time, the potassium chlorate, as a cause, was not even considered. Treatment with the mercury was continued. The tablets had all been used, and as the mucous patches had disappeared they were not renewed. In two days the eruption was gone. Six weeks later several mucous patches were again seen. These were cauterized and attention called to renewing the tablets. Three days afterward the patient returned with an eruption the same in character as before; the trunk and neck were involved, and several slightly raised erythematous spots were seen on the legs. The chlorate was immediately suspected, and its discontinuance ordered. In less than forty-eight hours the eruption had subsided. Since this outbreak the patient has, at my solicitation, twice used the tablets for a few days, and at both times its action on the skin followed. The tablets consisted of five grains each, and it required but fifteen to twenty to call forth the eruption. A similar rash has been recorded as occasionally following the use of mercury. The case here mentioned has suggested the idea that, in some of these instances, the eruption may have been due to the chlorate of potassium: as is well known, this is frequently employed to modify or lessen the action of the mercury on the mouth, and also for the purpose of influencing mucous patches. At all events, this possible action of the chlorate, as related in the above case, is well worth bearing in mind.

SURGICAL FRACTURE OF THE FEMUR.

By G. P. HACHENBERG, M.D.,

AUSTIN, TEX.

A SHORT time after the close of the late civil war the Surgeon-General of the United States army directed to be made to him army surgical reports of cases that might be of sufficient importance to incorporate into the "Medical and Surgical History of the War of the Rebellion." Of the number of cases I reported, whether from some oversight or of a disapproval of the surgical treatment of the case, my report of a surgical fracture of the femur did not make its appearance in the work among the operations of the lower extremities.

As the case was one of a formidable nature, and attracted at the time the attention of surgeons of both armies, I deem it of sufficient interest to place it on record, even at this late day.

In 1862-3, when in winter quarters at Buckhannon, W. Va., some of the surgeons of the brigade directed my attention to a Sergeant P—, of the First Virginia Infantry, who was shot with a musket-ball, through both thighs, fracturing the right femur, a little below the lesser trochanter, the ball being lost in the same limb. The case was generally considered as a suitable one for amputation at the hip-joint. As I had performed that operation a few years previously in civil practice, the patient was advised to place himself under my care. Following this advice he sent for me, requesting my services. Although he was confined at his home, about fifteen miles outside of our lines, from the general interest that was felt in the case I concluded to run the risk to reach him and perform the operation. It was strictly a volunteer duty, as the patient was never officially assigned to me.

By the aid of a guide I reached my patient in safety. I was there met by a neighborhood physician. I found the patient in bed, much emaciated, with the right thigh enormously distended and here and there perforated with fistulous openings. The ball passed through the left upper thigh (inflicting a wound that had healed up when I saw him) and penetrated the right thigh at Scarpa's triangle and fractured the femur.

He was wounded in a skirmish with the enemy, nine

months before the time I saw him. He fell into their hands and was examined by quite a number of their surgeons, but from the unfavorable prognosis of the case, no operation was attempted. His friends finally got permission to take him home, and to do so he was carried one hundred miles on stretchers. Not long afterward he was taken to a United States hospital at Wheeling, Va. Here, according to the patient's statement, he was examined by more than fifty visiting surgeons, and they, like their Confederate *confrères*, deemed it best not to operate on him, and under unfavorable prognosis he was held under a strictly surgical conservation. He gradually got weaker, as the suppuration and inflammation extended itself in the leg, and was finally permitted to return to his home.

Taking into consideration the condition of the patient I concluded not to amputate, but to enter into a dissection in search of the ball. By a careful palpation, I detected an ill-defined fluctuation, anterior to the upper third of the thigh. It took in a space nearly the size of my hand. The patient was placed under the influence of chloroform. I made here an incision in line with the femur into the deep fasciæ, and entered a large abscess. I carefully removed its contents, which was about a pint of sanious pus and a few spiculæ of bones that had exfoliated from the main bone. With my fingers I carefully explored the parts in search of the ball, and finally passed my finger into a sinus that terminated on the outside of the femur, where I detected by the touch a sharp projection of the ball. From the lower end of the longitudinal incision I made a transverse incision to the right, about six inches long. This gave me ample room to reach the ball and the necrosed bones. These incisions had necessarily to be extensive to correspond with the morbid enlargement of the limb. I applied bullet-forceps to the ball and made firm traction for its extirpation. But it was so firmly imbedded in ossification that I could not move it in the least. Persisting in my efforts to get it out, I broke and bent two bullet-forceps in the attempt, which were all the instruments of the kind I had with me. Here a painful crisis presented itself. There was but one question at issue, and that was that the ball and all foreign material in the limb had to come out and, owing to the condition of the patient, very quickly too.

To meet this terrible emergency I placed my left knee as a fulcrum under the hip-joint, or rather somewhat a little in advance of it, and struck the knee of the affected limb a sharp, firm blow, causing a fracture of the bone at the place where the ball was imbedded. This surgical fracture was easily effected at the proper place, owing to the presence of the ball and necrosed bones. I was now able to pick out with my fingers the ball, which was in two pieces, very much flattened out, and with the same facility removed all necrosed bones. I cleansed with care the entire wound with tepid water, and closed it up as the patient emerged from the influence of the chloroform, thus giving him more or less pain to favor reaction. Drainage from the cavity of the abscess was established, and to the outside of the wound I applied light compresses saturated with a weak solution of Labarraque's disinfecting liquid. The shock that followed the operation gave us much anxiety. For many weeks he was in a most critical condition, but being kept under a stimulating and sustaining treatment, finally convalescence was established, though long and tedious.

The cure terminated with considerable shortening of the limb, as might be expected, both from the original gun-shot fracture and the subsequent surgical fracture that was treated by position and not by splints. As I left the patient in an extremely exhausted condition, barely alive, so to speak, I advised the attending physician not to resort to splints, but to maintain the limb in the best and easiest position he could with the least tax to the patient. It was the life of the patient we struggled to save, and not the limb at the risk of life.

Progress of Medical Science.

THE INFLUENCE OF THE ELECTRIC LIGHT ON THE HUMAN EYE.—In discussing the value of any particular source of artificial light, says Professor Mauthner (*Wien. Allgem. Med. Zeit.*, No. 10, 1883), three qualities should be especially regarded: 1, the steadiness of the light; 2, the strength of the light; 3, its composition. From its complete failure in point of steadiness, the arc-light must be at once rejected from the category of lights suitable for the human eye. The incandescent lamp, on the other hand, deserves a prominent position. As regards its strength or intensity, it also fulfils all requirements, since it can be modified or intensified at will. The composition of the lights habitually used hitherto has shown a preponderance of yellow rays. In the electric light, however, the short-wave rays predominate—i.e., the violet rays. To the human retina, blue or violet tints are more agreeable than yellow, and hence from its composition, as well as from its steadiness and adaptability, the light of the incandescent lamp is especially adapted for the use of the human eye. Distinctness of vision and the perception of color are both increased under the electric light—facts which might be theoretically held to involve an overstrained retina. Such a theory is not, however, borne out by practical experience; it is only where the light employed is unsteady that any ill effects have been observed. It may be considered as an established axiom, that the brilliancy and composition of any light are as nothing, in respect of its value as an illuminating medium for ordinary uses, compared with its constancy and steadiness. In the incandescent lamp no combustion takes place, and hence no consumption or vitiation of atmospheric air is induced. From a theoretic point of view, therefore, no objection can be raised against the use of the incandescent electric lamp. Its full value as an illuminator is, however, not yet ascertained.

AEDOMINAL INUNCTION DURING PREGNANCY.—Dr. Burke, in the *New England Med. Monthly*, says: "In the last three or four months of pregnancy all women suffer discomfort from the distention of the abdominal walls, which I have found greatly relieved by the free use, at least once a day, of some unctuous material, as vaseline or sweet lard, and in many cases the formation of the lineæ albicantes is prevented."

THE SECRETIONS IN MORPHIA POISONING.—Dr. Marmé, of Göttingen, communicates (*Deutsche Med. Wochens.*, April 4th) a paper on his investigations of the urine and other excretions in morphia poisoning, undertaken partly on patients, partly on animals. He finds that morphia can be recovered unaltered from the urine when the amount taken is not less than one-seventh grain daily. When larger doses are taken, it is found also in the fæces. Instead of morphia, Dr. Marmé sometimes found "oxydimorphin" in the excretions and in the tissues, and he found by experiment that this substance was present when a poisonous dose had been administered in very small quantities at a time, and the symptoms resembled those of the abstinence stage of morphia intoxication. From his experiments Dr. Marmé has formed the opinion that morphia may be left off suddenly in very strong well-nourished individuals, but that in weakly persons it is necessary to diminish the dose gradually.

EXTIRPATION OF THE LARYNX.—Dr. Müller reports upon this subject in the *Gaz. Méd. de Strasbourg*. In April, 1881, extirpation of the larynx was performed by Professor von Winiwarter for an adeno-carcinoma of the larynx, with diffused epithelial infiltration. There was no return eleven months after the operation. The patient did not use her artificial larynx, finding that deglutition was impeded thereby. She wore a fenestrated tracheal

canula, communicating by the opening with the pharynx and provided with a mouth at its external orifice. She breathed quite freely and could swallow both liquids and solids with ease. Articulation was almost without sound, but was sufficiently distinct for her to be heard and understood. Of the forty-three cases of extirpation of the larynx hitherto published, thirty-two have been undertaken for carcinomatous, six for sarcomatous growths, and two for tertiary syphilis. Of the six performed for the removal of sarcomata in only one has the growth returned, the other patients up to this time having remained free six years, two years, seventeen, fifteen, six, and four months respectively. In the removal of carcinomata the prognosis is less favorable; of the thirty-two cases published, there are only two in which the patient has remained free eleven months, the frequency and rapidity of the return being almost always due to the great extent of the lesion and invasion of the neighboring parts. The mortality, moreover, is much influenced by septic pneumonia, this having been the cause of death of nearly all the patients who have succumbed in the course of the first few days after the operation. To avoid the entrance of foreign bodies into the air-passages, Dr. von Winiwarter brings the anterior wall of the œsophagus over and in front of the trachea, and fixes it with sutures to the cutaneous wound. To avoid septic pneumonia, the parts are dressed with iodoform and covered with iodoform gauze. Practised early, in the absence of glandular infiltration, and with the employment of iodoform to remove the danger of septic pneumonia, extirpation of the larynx would appear to be a more hopeful procedure than is generally supposed.

NITROUS OXIDE AS AN ANÆSTHETIC IN LABOR.—Dr. Tittel gives a report (*Wiener Med. Blätter*, March 15th) of over fifty trials which he has made of the inhalation of nitrous oxide gas in parturition. He employed it chiefly in primiparæ with very severe pains, and found a diminution of the suffering in every case. He found it acted better when given in the first stage, as its effects lasted into the second, and quiet inhalation was more difficult when it was attempted to be given in the second stage. The pulse was generally retarded, and the foetal pulsations, on the contrary, generally accelerated. The pains were in many cases increased in strength and frequency, and Dr. Tittel found this action of the gas very serviceable in multiparæ with few and weak pains. Vomiting was arrested in four cases by the inhalation of the gas, and the only evil results which were observed were two cases of convulsions, one hysterical and the other true epileptic.

MELÆNA NEONATORUM.—Dr. Epstein, of Prague, discusses this subject in the *Allgem. Wiener Med. Zeit.*, and points out that the occurrence of hemorrhage from the stomach and intestines of new-born children is by no means uncommon. He considers that a distinct disposition to hemorrhage from various organs must be recognized as belonging to the first few days of life. This disposition is made manifest or increased, when either disturbance of circulation, or disease of vessels, or of the blood itself, is present. The notable alteration in the circulation which takes place at birth must therefore be regarded as a principal cause of the hemorrhage, and especially in cases of protracted labor, or of children born in a state of partial asphyxia, or of weakly children with atelectasis of the lungs. Various conditions have been found in the gastro-intestinal mucous membrane: hyperæmia, hemorrhagic erosions, ulcerations, and actual hemorrhage. In many cases, where the mucous membrane of the stomach has been found sprinkled with small ecchymoses, small rounded ulcers have been discovered; and these have by some authors been regarded as the real cause of melæna neonatorum, the ulcers themselves being brought about by thrombosis or embolism of the gastro-duodenal vessels, secondary to thrombosis in the umbilical vein. This is probably, however, the

rarest cause for the hemorrhage; the most common cause being the hyperæmia and temporary congestion of the finer capillary vessels. Although ulceration may take place with extreme rapidity after birth, it would appear that it is usually of intra-uterine origin; and several cases are recorded where such ulceration has led to actual perforation of the intestine or stomach. Another group of cases is formed by those of children infected with septic diseases or the subjects of hereditary syphilis. In the latter cases the hemorrhage may be the only evidence of the disease, the liver being found free from any syphilitic mischief. In the cases in this group, the prognosis has been clearly shown to be unfavorable. About half of the cases end fatally, and the immediate cause of death is usually the hemorrhage itself. A few cases, however, recover with marked rapidity.

CERVICAL PACHYMEINGITIS.—Charcot (*Le Progrès Méd.* No. 19, 1883) describes a case of paralysis due to cervical pachymeningitis. He points out that such cases pass through three stages: 1, the neuralgic period, characterized by severe pains and sense of constriction in the chest, a stage which lasts four, five, or six months; 2, the paralytic period in which paralysis occurs, accompanied by muscular atrophy; and 3, the spasmodic period, in which the lower limbs are affected by a spasmodic paraplegia, the result of a transverse myelitis with descending degeneration of the lateral columns. The pathology of this affection is an inflammatory thickening of the dura mater, which may involve to some extent the nerves passing through it and the adjacent end, but in the main the symptoms are due to the compression of the inflamed membrane. Such cases occur independently of any diathesis or specific cause, often as the result of living in a damp place. Ultimately recovery may take place. In the case quoted this occurred partly spontaneously, partly as the result of treatment which chiefly consisted of the actual cautery over the seat of the disease. Afterward there remained great contraction of the hamstring muscles, but these were divided subcutaneously, and by electricity and friction the patient recovered so far that he could walk about the hospital and go the distance of a mile without much fatigue.

LAPAROTOMY IN THE NEW-BORN.—At a recent meeting of a medical society in Vienna (*Wiener Med. Blätter*, Dr. Felsenreich showed a child, two weeks old, on whom he had performed a radical operation for the cure of umbilical hernia. The birth had been easy and natural, and the child itself was strong and healthy, with no other malformation. A tumor of the size of a lemon was situated in the abdominal wall, the umbilical cord being attached to its summit. The separation between the recti muscles was eight centimetres long and four centimetres broad, and contained intestines and the margin of the liver. Twelve hours after birth the operation was made in the usual way, the hernial sac being attached to the edge of the skin-wound, which was closed by twelve silk sutures, and dressed with iodoform. The operation was completed in twenty minutes, without much sign of pain on the part of the child, which took the breast immediately afterward, and had a normal stool on the second day. The progress of the case was very satisfactory throughout, although the healing of the skin was somewhat slow.

INVISIBLE CUTANEOUS PERSPIRATION IN HEALTHY AND FEBRILE CHILDREN.—Dr. Eckert, in the *Pratch*, publishes the results of her observations on thirty healthy children from two to fourteen years of age, and on twenty-seven suffering from various febrile diseases. The age of the febrile children varied from eighteen months to thirteen years. The conclusions at which the author has arrived are summed up thus: *a. For healthy children.*—1, invisible loss of water by the skin in children proceeds with greater energy than in adults; 2, the loss is greatest in children of younger age (under five years), and gradu-

ally becomes less as age, height, and weight advance; 3, all conditions being equal, any rise of barometric pressure increases loss of water by the cutaneous surface, while any increase of the humidity of the surrounding air inhibits invisible perspiration. *b. For febrile children.*—1, in the febrile state invisible perspiration is augmented; 2, in enteric fever, the greatest loss of water by the skin coincides with the period of maximal mean daily temperature, afterward invisible perspiration decreases with the fall of febrile temperature, and in the period of convalescence it descends considerably below the normal level; 3, similarly, in the course of relapsing fever, there is observed more or less considerable increase in invisible perspiration during the attacks; having reached its maximum at the time of crisis the amount of evaporation rapidly falls, though during the first twenty-four or thirty-six hours after the crisis it remains still rather increased above the standard. During the apyretic intervals and after the termination of the disease cutaneous loss of water falls below the usual level; 4, in scarlatina invisible perspiration is considerably increased.

TROPHIC DISTURBANCES OF THE SKIN IN ATAXIA.—Drs. Ballet and Dutil report (*Le Progrès Médical*, No. 20, 1883) three cases of a sort of ichthyosis of the skin of the anæsthetic or hyperæsthetic regions in tabes. The skin was usually reddened, lax, thrown into folds, and the epidermis was increased in amount and sometimes desquamating. They summarize these results in the following propositions: 1. In tabes we may observe permanent trophic disturbances of the cutaneous system. 2. These trophic disturbances are very different in appearance and evolution from those hitherto described. The skin-eruptions (herpes, etc.), ecchymoses, and even perforating ulcer, are the effects of simply transient and accidental phases. Ichthyosis is, on the contrary, a dystrophy of slow evolution, apparently progressive, like the lesions of bone. 3. This dystrophy is manifested by a kind of thickening of the skin, with more or less deepening of its color, laxity of the integuments, desquamation of the epidermis, the *débris* of which sometimes accumulate so as to form true scales on the surface of the skin. 4. The regions in which these changes are observed are also those in which marked disturbances of sensation may be found, lightning-pain, anæsthesia, hyperæsthesia to cold, to pricking, sometimes to simple contact. The extremities are the parts generally attacked. The skin of the back of the hand may come to resemble the skin in pellagra. 5. The loss of the nails and their alterations, as described by Joffroy, Pitres, Roques, and Dorneaux-Juron, seem to be examples of this cutaneous dystrophy, affecting the matrix of the nail.

GALIUM APARINE AS A REMEDY FOR CHRONIC ULCERS.—Dr. Quinlan (*British Medical Journal*) has treated cases of chronic ulcer with great success, by means of poultices made from "Cleaver's" (*galium aparine*). It has been, he states, used with the most marked success in the following manner. Grasping in the left hand a bundle of ten or twelve stalks, with a scissors held in the right hand, the bundle is cut into pieces about half an inch long. These are thrown into a mortar, and pounded into a paste. This paste, which has an acrid taste and slightly acrid smell, is made up into a large poultice, applied to the ulcer, and secured with a bandage. It is renewed three times a day. Its action appears to be a slight, steady stimulant, and powerful promoter of healthy granulation. Its effect in one most unhelpful case was decisive and plain to all. Healthy action ensued, and has since steadily continued: and, after a month of treatment, the two ulcers have been reduced to considerably less than half their original size. A difficulty at once suggests itself as to its general employment, viz., that in winter and spring it is not to be had at all. It appears, however, that this difficulty can be effectually met by the method of ensilage, by

means of which green food for cattle has for the last few years been kept perfectly sweet and fresh by burying it in silos under the ground. This plan is generally known, but all particulars about it can be learned in the pamphlet of Mr. Thomas Christy, F.L.S. (Christy & Co., 155 Fenchurch Street, London, E.C.). In the case of the galium, the process would consist of cutting the herb very fine, ramming it down by screw-pressure into a glazed earthenware jar with an air-tight cover, and burying it in the ground. Thus secured from air, moisture, and heat, it would be likely to keep through the winter. This plan, if successful, might be extended to other pharmaceutical herbs; for Dr. Quinlan has always had the idea that green herbs are more powerful than dried ones. Indeed, the late Mr. Donovan, of Dublin, used to maintain that, to make tincture of digitalis properly, the alcohol should be brought to where the foxglove was growing, and the live plant plunged into it.

IMPERFORATE HYMEN PERSISTENT IN LABOR.—In the *British Medical Journal*, May 12, 1883, Dr. Edwards describes the following case: At 11 P.M., April 25, 1883, he was called to see S. O——, primipara, aged thirty-two, said to have been in labor since Monday morning, the 23d ultimo. He found the patient suffering from severe "pains." On digital examination, he was somewhat surprised to find that the orifice of the vagina was completely closed by a tough membrane. Anteriorly, it was comparatively thin, and attached to the edge of the vaginal orifice, whence it sloped gradually backward until, at the posterior wall, it was attached an inch and a half from the orifice. Here it was very thick, and gave the same sensation to the finger as the walls of the vagina itself. The foetal head could be easily felt through the tissue, which was perfectly lax, resisting all efforts at rupture with the finger. Having decided to give the uterus time to do its best, he left, calling again at 4 A.M.; but, though the pains had been strong and frequent, things were much in the same condition. By sawing with the nail at the thinnest part, he eventually got the end of his finger in, and tore the hymen by drawing the finger backward, until about half way across, but he could not manage it farther. He then waited an hour, in the hope that the remaining half would not be sufficient obstruction to delivery; but, "pains" becoming short and slight, he put on a forceps, and delivered without difficulty. The patient went on satisfactorily. This case is medico-legally interesting, as showing that one single act of copulation, in spite of the seeming difficulties of the case, sufficed for impregnation.

CYSTOTOMY BY A MODIFIED LATERAL METHOD.—Mr. Reginald Harrison writes to the *British Medical Journal* that the selection of a method for opening the bladder should have reference only to the object to be attained, or the contingencies that may arise. If, for instance, we desire merely to introduce the finger into it, as a preliminary to extracting a small stone, the median operation answers perfectly; while, if a larger stone, or an unknown quantity of anything has to be dealt with, the lateral incision will, as a rule, be preferable. It has been advanced by those who favor the median incision, which is practically an urethrotomy, that it is both simple and safe; its admitted disadvantage lies in the comparatively small space it provides for manipulating and extracting; while, on the other hand, the lateral incision, though affording more room, is considered to be attended with an increased risk and a greater degree of difficulty, so far as its performance is concerned. The median operation need not necessarily involve anything more than the opening of the membranous urethra. The completed lateral operation further includes the division of structures constituting the neck of the bladder; and it is to this part of the proceeding that any increased risk or difficulty is to be attached. A little reflection shows that it is possible to closely assimilate the lateral with the median operation, that is to say, to dispense with the incision, not to the

staff, but along the staff, should it be found, on exploration with the finger, that the additional room which the latter part provides is unnecessary for the object in view. It need hardly be said that this modification of the lateral method, where it is found, on digital exploration, to be feasible, frees the operator from executing the only portion of the operation to which any increased risk is attached; while, on the other hand, he has the consciousness that, should it turn out to be necessary, he can, by the completion of the deep incision along the staff, avail himself of all the advantages which are conceded by surgeons to the lateral method of opening the bladder.

THE OXYTIC ACTION OF QUININE.—Dr. Hartigan, in the *British Medical Journal*, June 2, 1883, says that, in three different cases he had to discontinue the use of quinine, because it brought on "labor-pains," though the doses used were small, varying from three to five grains. In one of these, during a previous pregnancy, another medical man used quinine, and discontinued it for a similar reason. All three were in fair general health, suffering only from slight malarious fever, and had never aborted. One case has come under his notice in which abortion took place, without apparent cause, after a ten-grain dose of quinine. The patient was the mother of several children, had not previously aborted, was in good health, and took the quinine to cure facial neuralgia. This action of the drug is known to the Chinese, who take it for the purpose of producing abortion, following its use by copious draughts of hot tea. Quinine certainly, in some cases, increases the menstrual flow.

HYSTERICAL TRANCE.—Dr. Rosenthal reports an interesting case of hysterical trance in which a country practitioner declared death to have ensued. A looking-glass held to the mouth did not show any moisture, and melted sealing-wax dropped on the skin caused no reflex movements. Rosenthal, who was accidentally present, found the skin pale and cold, the pupils contracted and insensible to light, the upper and lower extremities relaxed, the heart's impulse and the radial pulse imperceptible. Auscultation, however, showed a feeble, dull, and intermittent sound in the cardiac region. No respiratory murmurs were audible. All the muscles of the face and extremities responded well to the faradic current. Although the patient had been apparently dead for thirty-two hours, he thereupon informed the relations that it was only a trance, and recommended that attempts at resuscitation should be perseveringly followed. On the following day he received a telegram to say that the patient awoke spontaneously twelve hours afterward, and gradually recovered her speech and movements. Four months afterward the patient called upon him, and informed him that she knew nothing of the commencement of her attack of lethargy; that she had afterward heard the people about her talk of her, but had been utterly unable to give the slightest sign of life. Two years afterward she was still alive and tolerably well. Rosenthal appropriately likens this condition to that of "nightmare," where, in spite of distressing sensations, the dreamer is unable to call for help or to make any movement which might save him from some imaginary impending danger.

EFFECTS UPON LOCAL TEMPERATURE OF NERVE-STRETCHING.—Dr. Redard has determined, from experiments upon dogs and rabbits, that the temperature of a leg falls 1° to 2° C. immediately upon stretching the sciatic nerve. Exceptionally there is at first a slight rise, followed speedily by a lowering of the heat of the part. It is worthy of note that the temperature of the opposite leg also falls slightly, a fact which would go to show that nerve-stretching exerts some influence upon the central nervous system. The temperature of the sound side rises to the normal in a few days, while that of the other side requires months for its restoration.—*Centralbl. für Chirurgie*, April 21, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 21, 1883.

CONCERNING HOSPITAL INTERNES.

THE letter of a late resident in one of our metropolitan hospitals brings up some questions which are not often discussed. They are eminently proper ones and can be viewed consistently from several stand-points. There is no doubting the fact that the relations at present existing between the visiting and house staffs of many of our large charities could be much improved by a better appreciation of mutual obligations.

It is too often supposed by the visiting physicians and surgeons that their whole duties are performed when the patients are simply prescribed for, and the necessary directions to such an end are given to the resident. By a large majority of men holding hospital appointments little else is done. The consequence is that the house staff becomes careless, apathetic, and shiftless. There is not that interest in the cases which they would, under other circumstances, gladly feel, not that incentive to study, which is always associated with the reception of new ideas with the opening up of new fields of inquiry. An interesting practical teacher always develops earnest and energetic learners. The steel and the flint are made for each other, and when each fulfils its function there is no trouble in getting the spark. But there are men in this city who occupy positions in some of our large hospitals who make no pretence at teaching; who feel no more concern for the resident than for the chief nurse. Hence the cause for just complaint on the part of our correspondent. The interne has a right to feel that something is due him in the way of practical and painstaking instruction at the bedside. There are many ways of doing this, but the nearer the student can get to the patient the better. There is nothing like feeling disease, so to speak. The house staff should have the fullest opportunities for this sort of study at the bedside, and under the direction of the attending physician or surgeon. It should be an education of the senses as well as of the intellect. As no one can get too much of such training nothing can be wasted on the student. No one feels a pulse intelligently, listens to a râle or murmur, appreciates a crepitus, recognizes a cast, passes a catheter, or even opens an abscess without learning something more each time. But how few of our hospital teachers care to take this trouble goes without the saying. There is altogether too much catering to the ordinary medical student, too much ambition to feed large clinics, too much of a desire to secure interesting cases for the amphitheatre to

allow of that more practical and profitable teaching in the ward, and in actual contact with the patient, which every student who wishes to treat disease finds sooner or later to be a fundamental necessity of his medical education. When so much is done by wholesale and long range, when patients are seen only through an opera glass, and the student merely told what he should hear and see, there is, of course, considerable difficulty in bringing the producer and consumer together. But the hospital interne has gone through this kind of instruction, he knows how little there is in it, and has a right to ask for better opportunities.

We should be sorry to say that this neglect of the internes was the rule, we hope it is not. We know that there are many hospital teachers who are doing this kind of teaching quietly and efficiently, and with very satisfactory results. But on general principles the foundation of the complaint of the ex-resident is a good one, and there is a great chance for the necessary improvement. The show of benefits is retroactive all around. Patients are better cared for, visiting physicians and surgeons become more attentive, internes more zealous, science more advanced, and the reputations of the hospitals better established.

It is not our intention to do more than allude to one or two points in the ex-resident's letter. Certainly a very important one is that which refers to the necessity of giving necessary instruction to gentlemen who are to administer anæsthetics. We are surprised to learn that this is not done more universally. To know how to administer an anæsthetic properly is high art. It requires knowledge in the first place and experience in the second place. From all accounts, those who administer anæsthetics, have as a rule neither of these advantages. Next to that of the operator himself, the administrator of ether or chloroform has the greatest responsibility of any around the table. In view of this fact, acknowledged by all experienced surgeons, it is certainly strange indeed that the junior assistant should be selected for this duty and that too without any other instruction than he can pick up from his own experimental endeavors. This certainly should not be. The most experienced man of all should be selected for this duty; in fact it would be wiser and better to have an anæsthetizer attached to each hospital. But the least of all that can be said when nothing better can be done, is that the juniors should be most carefully instructed before being intrusted with lives of patients during the critical periods of formidable surgical operations. And yet such is done in almost every large hospital in this city, and under the eyes of the most experienced surgeons. One is almost made to think that the administration of ether is a matter of very little consequence, that deaths do not occur from carelessness, and that the patient has little if any right to careful and skilled treatment during a time of utter helplessness and dangerous probabilities. Our correspondent does not put the case a whit too strongly, in urging a radical change in our ordinary methods of ether administration.

THE PROFESSION'S GREATEST NEED.

IF we were to ask the average practitioner in city or country what was the greatest single obstacle to his progress, he would doubtless say, a field too much occupied. It is the constant appearance of new men,

young, eager, and hopeful, which cuts off here and there the extension of his practice, and which threatens to narrow down that which he already possesses.

Protection against a horde of superfluous rivals is what the general practitioner, who is himself well equipped and competent, most needs.

How can he secure this protection? There is but one way which is at all practicable, and that is by elevating the barriers, so-called, which now mark the entrance to the medical profession.

If every college in New York State was obliged to give a four years' course, if the graduates and outsiders were obliged to submit to an examination by a Board before they could get a license, should we have ten thousand doctors in this State with only three thousand fit to go in the Green Book?

Now, since there is in our State, as well as in most others, an evil so palpable, so obtrusive, so pernicious, that not an educated physician fails to see and feel it; and since there is also a partial remedy for it at least, we say that the profession ought to devote its strongest energies to applying this remedy, to elevating the status of medical education, and to keeping incompetent excess from its ranks. Here is "something worth fighting for," as our contemporary of Buffalo has well said.

The practical result of changing the old Code to the new Code, or the reverse, will now be trivial. Doctors will act as their characters determine them to act. The President of the American Medical Association says that the by-laws of that association permit consultations with irregulars, others think they do not. He (the president) thinks these by-laws should be changed; the Judicial Council think not. The matter as it stands is in an admirable state of complexity.

Meanwhile we say to our readers and to physicians everywhere, work for what most affects your daily bread; protect yourselves by reforming the methods of educating and licensing medical students, by laying a hand upon the colleges, and saying, "We protest against college professors growing rich on the fees of these half-educated, two-term doctors whom you turn abroad every year to compete with us."

In the light of the real needs of the profession few things could be more scandalous, than that medical colleges should advertise themselves as supremely ethical when they have not the courage to sustain long courses or even to demand preliminary examinations. The matter is in a nutshell. There is money in being orthodoxly ethical; but a three-term course, a careful educational system, is expensive.

THE PRODUCTION OF HEAT IN THE BODY.

A DISCUSSION of certain heat problems is particularly appropriate at this season. The investigations of Helmholtz, Dulong, Frankland, and Barral have shown quite definitely the source, amount, and loss of heat in the animal body, in other words, the heat-balance during the twenty-four hours. The unit usually employed now in these measurements is the "Calorie," which is the amount of heat required to raise one kilogramme of water one degree Centigrade. An adult man breathes in daily about ten thousand quarts of air, of which one-fifth is oxygen.

This oxygen is distributed through the body, firing the different tissues. It is at last thrown off in union with C, as CO₂, of which the amount is 878 grammes daily (Scharling), and in union with H, as water, 13,615 grammes daily. The total amount of heat produced by this chemical action of the inspired oxygen is estimated by Helmholtz to be about 2,050 calories. It is an amount of heat that would raise 4,200 pounds of ice-cold water from 32° F. to 33.8° F.

But besides this, it is estimated by Dulong that about twenty-five per cent. more of heat is produced from other sources, *i.e.*, from the food. This makes a total of 2,550 heat units produced daily by an adult man who is not engaged in muscular work.

The heat thus produced is almost entirely lost by radiation and conduction (seventy-three per cent.) and by evaporation of sweat (14.5 per cent.) from the skin. Only about ten per cent. is lost by the lungs, and two per cent. by the excretions and the introduction of cold food and drinks.

The difference, however, between the amount of heat produced during a day of rest and one of work is very great, and the figures are suggestive, if not instructive at this particular time. During active muscular work the amount of heat developed by an adult is more than half as much again as when one is at rest. The ratio can be best expressed as follows: A man sitting quietly in his room, indulging in no excessive vituperation against obtrusive flies, generates about one hundred heat units (calories) an hour. If he falls asleep, this amount sinks to forty or fifty calories per hour. If he wakes up and insanely attempts to chop wood, the amount rises to one hundred and fifty calories or more per hour.

The hygienic deductions to be drawn from the foregoing are: Keep the body quiet, and the skin active. It is a fact, which should be mentioned here, that large draughts of water do not necessarily produce diaphoresis unless the water is hot. The absolute cooling effect of a large tumbler of ice-water is trivial. In raising it to the temperature of the body the equivalent of about ten units of heat is abstracted.

THE DIAGNOSIS OF MOVABLE KIDNEYS.

It is an evidence of the minuteness and care with which modern medical science attacks the various problems before it when we find a whole book devoted to the diagnosis of "l'ectopie renale," or misplaced movable kidney. Dr. Frédéric Buret is the author of such a work,¹ and it is a contribution of practical value to physicians. Although less than one hundred cases of movable kidney have been, so far, reported, it is a trouble which is no doubt much more frequent than is supposed. Such is the opinion of Buret, and Dr. William Roberts, and others, and it is strongly supported by the investigations of Oppolzer, who in a series of five thousand five hundred patients found that twenty-two had movable kidneys, giving a proportion of one in two hundred and fifty. It is not improbable, as Roberts says, that many cases of obscure abdominal pain and of gastro-enteric disturbance are due

¹ Du Diagnostic de l'Ectopie Rénale, par le Dr. Frédéric Buret, Aux Bureaux du Progrès Médical, pp. 93. Paris, 1883.

to this cause. Movable kidney occurs in women much oftener than in men, the proportion being as six to one. It is generally an acquired trouble, and its existence is due chiefly to parturition, tight-lacing, sympathetic renal congestion during menstruation, and violent exercise or injury. The most prominent symptoms are, a dragging pain in the loin, and gastro-intestinal disturbances, nervous symptoms, hysteria, and hypochondriasis may also be provoked by it. Epigastric pulsation is often present, but the only certain evidence of the trouble is, of course, the presence of a movable tumor which can be felt.

The chief value of Dr. Buret's work is in the collection of cases which he has made illustrating mistakes in diagnosis. These cases, fifty in all, he divides into three classes: 1st, those in which no tumor was recognized, and no idea of the real trouble was obtained; 2d, those in which a diagnosis was vaguely formulated; 3d, those in which a tumor was discovered but its nature not recognized.

In the first class he cites fifteen cases. These had been treated as cases of crural, or lumbo-abdominal neuralgia, of renal colic, hepatic colic, *embarras gastrique*, hysteria, and chronic peritonitis.

In the second class, the trouble had been mistaken for "abdominal tumor," and "affection of the liver." Moxæ were applied in some cases and operation suggested.

In the third case, a diagnosis was made of biliary obstruction, enlarged liver, tumor of right lobe of the liver, cancer of the liver, enlarged gall-bladder, biliary calculus, cancer of the pylorus, displaced spleen, and ovarian cyst.

The list thus given sufficiently illustrates both the inventive imagination of the doctor and the various symptoms which renal ectopia may produce.

SEXUAL ADVERTISEMENTS.

SOME time ago we called attention to the fact that certain enterprising medicine-vendors were hiring men to promenade Broadway, bearing dorsal and ventral placards, which announced the virtues of a certain drug in sexual weakness. The erotic procession referred to appeared then, as it does now, strikingly suggestive of the ancient orgies of Priapus; but it was only a sign of the times.

The Americans are the most advertising of all nations, and it is to be expected that helps for the erring and erythritic should nor be left out. Nevertheless, a line should be drawn, and we submit that remedies for sexual disease are now being forced before the public to an excessive, disgusting, and injurious extent. A person walking one of the side avenues of this city is liable to have thrust into his hand the card of a gonorrhœa specialist, or the advertisement of a safe, sure, and speedy cure for certain sexual ills. Telegraph poles and fences are placarded with condensed but significant descriptions of choice measures in urethral therapeutics; our larger concert gardens, in which beer and music are dispensed to the temporary comfort of the flesh, contain upon their programmes notices of potent "urethrines" and pocket syringes. As for the press, we have already commented on the drift of the religious impulse as evidenced by the advertisement of gonorrhœa cures in the religious

weeklies. The secular papers have long been filled with every sort of sexual advertisement.

Perhaps all this is part of our evolution and cannot be helped; nevertheless, it might be worth while making a little effort to check it. It is injurious to public morals and public health, this constant obtrusive forcing forward of sexual drugs and the sexual system. Besides, decent men and women would like to be able to look at a fence or a telegraph pole without finding the cut of "The Perfect Syringe" focussed on their retina. There is a law against committing nuisances, which perhaps Mr. Comstock might interpret to the public's advantage here.

THE NATURE OF PEPTONE, AND ITS FORMATION OUTSIDE THE DIGESTIVE TRACT.

DR. ALEXANDER POEHL, of St. Petersburg, in an inaugural thesis, has presented the results of his researches into the nature and formation of peptone. Some of the results which he announces are novel and deserve consideration.

Poehl investigated different tissues and fluids of the body in order to discover whether peptone could be found outside of the gastro-intestinal tract. His results confirmed what had already, to some extent, been shown, that peptone does exist in these places. Thus, it is found in appreciable quantity in the blood, in urine, sweat, sputa, the fluid of ovarian cysts, in hydrocele, in cancerous tissue, in the pus of cold abscesses, and in pleuritic exudation. Poehl found peptone in sixty-five per cent. of the specimens of urine obtained from two hundred and thirty-three febrile cases in Eichwald's clinic. He found it in cases where the urine was neutral or alkaline, thus disproving, as he thinks, the view that it is the result of a digestive action occurring in that fluid. He also found that normal filtered acid urine had no peptic acid when brought in contact with albumen.

In order to explain the presence of peptone in these various fluids, Poehl undertook a series of experiments for the purpose of finding whether there was not some peptic ferment in the tissues themselves. His results corresponded with his expectations. Fresh macerated kidney, acidulated and placed in solution with albumen, displayed a peptic action, considerable peptone being produced after a few hours. The same result was obtained with lung-tissue and with pieces of the small and large intestine. Poehl concludes, therefore, that the tissues of the body all (!) have some peptic power. In croupous pneumonia the ingenious hypothesis is offered that the ferment of the lung-tissue digests and dissolves the exuded fibrin. In confirmation of this view he cites the fact that in croupous pneumonia peptone is present in considerable amount in the urine. Our author also brings some evidence to show that not only animal but vegetable tissues have this digestive power. He seems to have experimented himself only with lettuce leaves, however, and it must be confessed that he draws his conclusions from a rather small series of experiments.

A chapter is devoted to the methods of turning peptone back into albumen, a process which is no longer new.

Poehl offers some original suggestions as to the real nature of peptone and the peptonizing process. There

have been three views held by physiological chemists as to this matter.

Thiry considered albumen and peptone to be simply isomeric. Herth, also Loew and Bokorny, consider the albumen, into which peptone is turned back, a "polymerization-product" of the latter.

Most physiologists, however, have of late held that the peptonization of albumen is simply a hydration and doubling-up of the proteid molecule. All admit that a certain amount of chemical action takes place.

Poehl contends, however, that peptonization, or, in other words, gastric and tryptic digestion, is a purely physical process, and consists simply in a soaking of the albumen with water to its utmost capacity. He finds that the ease with which the different albumens are digested or peptonized is in proportion to the rapidity with which this capillary imbibition takes place.

His view is based upon the fact that chemical analysis reveals no characteristic difference between albumen and peptone, and that the optical properties of the two bodies are also entirely alike. This latter fact he thinks could not be true if the two bodies possessed any real chemical differences.

News of the Week.

SUING FOR A DEGREE OF DOCTOR IN MEDICINE.—A medical student, Mr. Jacob M. Davis, applied for a mandamus to compel the Faculty of the Baltimore College of Physicians and Surgeons to confer on him the degree of M.D. Mr. Davis alleged that the Faculty refused to graduate him after he had attended a two years' course of lectures, on account of his parents, and not for any personal unfitness on his part. It was urged by his counsel, C. Dodd McFarland and H. M. Tiralla, that even if the objection to parents was a valid reason for rejection, it should have been made when he entered as a student. Mr. John T. Morris, for the Faculty, said the Faculty may not have known of the ground of objection earlier. He contended that the act of the Faculty could not be inquired into by the court. Judge Phelps said a mandamus ought not to be granted when there is a remedy by suit, and hence it was denied.

AN EPIDEMIC OF GLANDERS.—The State Veterinarian of Illinois reports that glanders is prevalent among the horses in nineteen counties in that State. He claims to have been prevented from killing the animals afflicted, the attorneys of the owners contending that he could only resort to this measure after the governor had issued a proclamation declaring the glanders epidemic. The Attorney-General is now expected to give an opinion as to the powers of the State Veterinarian under the State laws.

EIGHT MORE ASSISTANT SANITARY INSPECTORS were appointed by the City Board of Health this week.

THE PROGRESS OF THE CHOLERA.—The probability that cholera would reach Cairo, which we suggested last week, turns out to be realized. On July 15th the disease appeared in a suburb of Cairo, and on the 16th several cases were discovered in the city itself. The

number of deaths in Damietta has fallen to about thirty or forty a day, simply because the population has flown or has already been destroyed. The disease has been steadily going up the Damietta branch of the Nile. It has appeared in a few outlying towns. The efforts to limit it by military sanitary cordons have been failures, because the lines were broken through. Some of the soldiers themselves have been attacked by the disease. Cholera has appeared among the British troops at Malta, and caused great consternation. The English are trying to justify their alleged negligence in the matter of quarantine by throwing the blame on the medical officers. There is said to be great difference of opinion among the Indian Government's medical advisers as to the question of human propagation of the disease, and the utility of quarantine. This is mere cavilling and casuistry, however, since there is no question that the weight of medical opinion throughout the world is in favor of the view of the utility of quarantine, and a government should accept the safest view, not the one most acceptable to its mercantile interests.

DR. JOHN A. WARDER, of North Bend, O., died on July 14th in the seventy-second year of his age. He was a prominent member of the American Forestry Congress, and the author of several works on fruit-growing and tree-culture.

ROYALTY AT A MEDICAL SOCIETY.—The discovery of the *bacillus* appears to have lent additional dignity and social favor to medicine. The Emperor William has deigned to apply his imperial and presbyopic eye to a microscope in order to see these organisms. And recently the Prince of Wales and Prince Lucien Bonaparte attended a *conversazione* given at the rooms of the London Medical Society on the occasion of the opening of an addition to the old buildings. The annual oration was delivered this year by Dr. Edward Lund, of Manchester, who discussed and advocated Listerism. His Royal Highness, with great judiciousness, waited until the oration was over, and then came in to the sound of music. A number of interesting objects were shown. Among them were some microscopic specimens shown by Dr. H. Gibbes, including the fungoid growth or organism, producing what is popularly known as the salmon disease (this preparation being illuminated by a cleverly arranged adaptation of the incandescent electric lamp); the *bacillus tuberculosis* in sputum, magnified 1,350 diameters; the bacilli found, in cases of typhoid fever, magnified 1,200 diameters; the *bacillus anthracis* and *spirilla vibrionis*. Other parasites specially affecting the lower animals were shown by Dr. Cobbold, and Dr. Francis Warner lent apparatus for obtaining graphic records of the movements of various parts of the body, and for enumerating these movements and their combinations. The honorary librarian, Dr. Allchin, had selected for exhibition some books from the valuable collection of old works belonging to the society, which comprises many dated in the fifteenth and sixteenth centuries from the library of Dr. Sims. Among these was the manuscript diary of the Rev. John Ward, in one of the fifteen volumes of which, under date of the years 1661-63, the writer had made the following entry: "Shakespeare, Drayton, and Ben Jonson had a merry

meeting, and it seems drank too hard, for Shakespeare died of a 'feavour' then contracted." Another interesting work was Dr. Mead's imperfect reprint of the "Restitutio Christianismi" of Michael Servetus, in which that ardent theologian and observant doctor illustrates an argument by a reference to the passing of the blood from the right side to the left through the lungs.

THE LEGAL VALUE OF HUMAN BLOOD—A CURIOUS SUIT.—A novel law-suit has recently been decided in the District Court of this city. Last February, a man went to a hotel, engaged a room, went to bed and blew out the gas. He was found in a condition of advanced asphyxiation, and lay for hours in an unconscious condition. Drs. Garrigues, Valentine, and Anderson were summoned to attend him, and after consultation decided that the only way to save the man's life was by transfusion. The proprietor of the hotel was accordingly instructed to hunt up a healthy subject who was willing to undergo the operation, and a colored porter, named Edward Banks, was called upon. The proposed subject was by no means inclined to serve at first, but when he was told that only about eight or ten ounces of blood would be needed, and that the blood would be paid for at the rate of ten cents a drop, his cupidity overcame his fears, and he submitted his arm to the instrument. Dr. Garrigues drew eight ounces and transfused it into the arm of the patient, who rapidly convalesced. Banks afterward served the patient as nurse, and claims that he was so overcome by a sense of the obligation which he owed to his preserver that he promised to reward him to his satisfaction. All that Banks received, however, was a five-dollar note in discharge of all obligations, and accordingly he brought suit for \$250 which his counsel claimed was the value of the blood at the price agreed upon, 10 cents a drop, together with the value of the nursing given the sick man by the plaintiff. It was estimated that an ounce of blood contained 240 drops, and 8 ounces at 10 cents a drop would thus be appraised at \$192, the value of the attendance, etc., bringing the bill up to \$250. The examination showed that the promise to pay 10 cents a drop was given in a joking way by one of the physicians, that the plaintiff was a poor man, and that he was nursed by his wife after the first day. Decision for the defendant.

YELLOW FEVER.—Reports of cases being brought to American ports are constantly printed. At date of writing, however, no case seems to have eluded the vigilance of the quarantine officers.

DR. THOMAS F. SCOTT, the oldest and one of the most eminent physicians of Petersburg, Va., died lately, aged eighty years. He was a nephew of General Winfield Scott and an uncle of General P. B. Starke. He was a member of the Virginia Medical Association and was widely known.

A PHYSICIAN'S SELF-DESTRUCTION.—Dr. Lee Pinkston, residing about fifteen miles from Montgomery, Ala., committed suicide recently, by placing a double-barrel shot-gun to his head and discharging it. He was suffering from mental aberration, caused by giving one of his children a fatal dose of morphine for quinine some time ago.

PASTEUR has offered to go to Egypt and study the cholera. Since the Pasteur-Koch controversy pathologists will want Pasteur to refurbish his old-fashioned methods a little before undertaking new fields of investigation.

DR. HENEAGE GIBBES has been appointed to the Chair of Physiology and Histology at the Westminster Hospital. His microscopic work is too well known to call for comment.

THE AMERICAN OPHTHALMOLOGICAL AND OTOLOGICAL ASSOCIATION held its sixteenth annual session at the Hôtel Kaaterskill, beginning July 18th.

DR. DONALD MCLEAN, of Ann Arbor, has been appointed Surgeon-in-Chief of the Michigan Central System of Railroads.

DR. W. E. QUINE, late of the Chicago Medical College, has been elected to the Chair of Practice of Medicine in the College of Physicians and Surgeons of Chicago.

PROFESSOR ALFRED C. POST has been formally requested to resign from membership in the American Medical Association on the ground that he has signed a paper stating that he is opposed to the present Code of Medical Ethics of the American Medical Association.

Dr. Post has for years sustained the reputation of being one of the best surgeons in the country, as well as being a gentleman of very extensive learning, and of the purest personal character.

It is evident now, however, that he is not a really good man.

THE NEW YORK POST-GRADUATE MEDICAL COLLEGE.—Dr. Charles L. Dana has been appointed to the Chair of Diseases of the Mind and Nervous System. Dr. J. Leonard Corning has been appointed Lecturer on the same branch.

DR. W. T. BELFIELD has been appointed Assistant Pathologist to the Cook County Hospital.

THE SUPPORTERS OF THE OLD CODE IN THE STATE OF NEW YORK.—The Council of the New York State Medical Association for Upholding the National Code of Ethics has issued a circular, dated June 21st, in which the numbers of those who uphold the old Code in the various counties of the State are given as follows: Albany, 40; Alleghany, 14; Broome, 28; Cattaraugus, 14; Cayuga, 20; Chautauqua, 26; Chemung, 21; Chenango, 46; Clinton, 27; Columbia, 14; Cortlandt, 22; Delaware, 16; Dutchess, 40; Erie, 107; Essex, 14; Franklin, 15; Fulton, 10; Genesee, 15; Greene, 17; Herkimer, 25; Jefferson, 23; Kings, 148; Lewis, 11; Livingston, 11; Madison, 19; Montgomery, 16; Monroe, 53; New York, 742; Niagara, 25; Oneida, 58; Onondaga, 66; Ontario, 21; Orange, 18; Orleans, 16; Oswego, 20; Otsego, 15; Putnam, 7; Queens, 44; Rensselaer, 74; Richmond, 11; Rockland, 9; St. Lawrence, 13; Saratoga, 27; Schenectady, 12; Schoharie, 12; Schuyler, 12; Seneca, 21; Steuben, 18; Suffolk, 18; Sullivan, 17; Tioga, 19; Tompkins, 13; Ulster, 19; Warren, 18; Washington, 10; Wayne, 24; Westchester, 44; Wyoming, 12; Yates, 9.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 23, 1883.

ALFRED C. POST, M.D., PRESIDENT, *pro tem.*

DR. SATTERTHWAITHE presented, in behalf of a candidate, a specimen of *pulmonary tuberculosis with marked thickening of the pleura, slight endocarditis, and acute nephritis.*

DR. FERGUSON presented, in behalf of a candidate, a specimen illustrating *subinvolution of the uterus.*

DR. SATTERTHWAITHE, from the Committee on Microscopy, reported that the tumor presented by Dr. Robert Newman, at the stated meeting held February 28, 1883 (see MEDICAL RECORD, vol. xxiii., p. 331), was carcinomatous.

DR. FERGUSON presented a specimen of

ANEURISMAL DILATATION OF THE HEART AND MITRAL STENOSIS—FIBROID INDURATION.

It was removed from the body of a man twenty-seven years of age, a native of Germany, single, and a clerk by occupation. Both his parents suffered from rheumatism, and his father, he said, died from asthma. Three years ago the patient first suffered from rheumatism, and at that time and ever since has been troubled with dyspnoea and cardiac palpitation. Three weeks previous to his admission into the New York Hospital, on March 12, 1883, his palpitation and dyspnoea became so aggravated that he was unable to attend even to light work. At the same time he began to suffer from a severe cough, the expectoration being scanty, white and frothy, and at times streaked with blood. His general condition was poor, and his respiration was much embarrassed. The apex-beat was in the mammary line and sixth space. There was a sound, presystolic and systolic in character, heard most distinctly at the apex, and transmitted to the right toward the sternum and axilla on the left side. The præcordial area of dulness was greater than normal. He was put on tonics and stimulants, and improved considerably, although he constantly complained of præcordial pain. In the latter part of March and during the month of April he was allowed to sit in his chair, and at times to walk about the ward. His cough almost entirely disappeared, there was no dyspnoea except on exertion, and his heart-action was considerably improved.

While in the hospital, temperature ranged between 99° and 102°; his respiration was slightly accelerated, and his pulse, feeble and easily compressible, ranged between 80 and 140 beats per minute.

The latter part of April he began to feel very weak, and was more closely confined to his bed and chair, but did not need any special attention. On May 2d, at 6 A.M., he died suddenly, without aggravation of the symptoms of which he complained since his admission.

Autopsy was five hours after death. There were one hundred and seventy-five cubic centimetres of bloody serum in the left pleural cavity, and seventy-five cubic centimetres of fluid similar in character in the right pleural cavity. There were old adhesions all over the surface of the left lung. Both lungs were congested and cedematous and deeply bronzed. The heart is large; the anterior wall of the left ventricle is bound to the pericardium by a firm band of connective tissue. The left ventricle is enormously dilated, and the left ventricular wall, in places, is less than one-eighth of an inch in thickness, and at the apex there is a portion of the left ventricular wall where the endocardium and pericardium are separated only by the interposition of a thin layer of fat. Posteriorly the ventricular wall is much thicker, being uniformly nearly one inch. The papillary muscles are much hypertrophied. The right ventricle is moderately dilated; the valves on the right side of the heart are

normal. The segments of the aortic valve are slightly thickened and retracted. There is stenosis of the mitral valve, admitting only a cylinder one-half inch in diameter. The endocardium is markedly thickened, and throughout the entire left ventricular wall there is increase of the fibrous tissue between the muscle-cells (fibroid induration of the heart), especially marked where the ventricular wall is thinnest, except at the apex, where there is no muscular tissue to be found. There is atrophy of the fibre-cells and much pigment arranged around the poles of their nuclei. The cells in places contain a small amount of fat, but generally the transverse striæ are well preserved.

DR. H. KNAPP presented a specimen of

MELANO-SARCOMA OF THE CHOROID.

The eyeball was removed a few days ago, from a man of about fifty-eight, who two years previously had noticed a cloud in the centre of the visual field of his left eye. The cloud became more intense, was perfectly black in the course of some months, and spread toward both sides, so that six months after the beginning he could see objects only in the upper and lower parts of his field of vision. An oculist diagnosticated detachment of the retina. In a year the sight in his left eye was completely destroyed. He consulted several oculists: the diagnosis was detachment of the retina. When he came to Dr. Knapp, two weeks ago, the external appearance of the eye was normal; the fundus not to be illuminated; sight lost, the eyeball tension moderately increased; other eye healthy. From the symptoms, Dr. Knapp thought the diagnosis of melano-sarcoma behind the detached retina in the posterior part of the choroid was about as sure as it could be without directly seeing the tumor. The enucleation proved the diagnosis correct: a flat, slightly nodular, black growth occupies the posterior third of the choroid, encircles the optic nerve. The retina is united to its surface, thence passes through the vitreous contracted into a cord, and attaches itself to the posterior diaphragm of the eye ciliary processes, zonula zinnii and posterior capsule of the lens. Dr. Knapp pointed out the typically clear clinical history of the case. During the first six months it must have been possible to recognize the tumor directly with the ophthalmoscope; in the last stage the diagnosis was secured by the increased eyeball tension in connection with the detached retina.

DR. GARRISH asked why Dr. Knapp diagnosticated so confidently a melano-sarcoma of the choroid without mentioning the possibility of a retinal tumor. He asked further at what age choroidal sarcoma was observed.

DR. KNAPP said that the intra-ocular tumors, with rare exceptions, were either gliomas of the retina, or sarcomas of the choroid. Glioma of the retina was a disease of childhood, no authenticated cases having been observed beyond the age of twelve years. Sarcoma was met with in young persons, though rarely; in middle life it was commonly unpigmented and past middle life pigmented.

DR. BEVERLY LIVINGSTON presented a specimen which illustrated

MULTIPLE UTERINE FIBROIDS.

It was removed from the body of a colored woman aged thirty years, who was admitted to the Home May 21, 1883. The patient on admission, in the afternoon, did not complain of any severe pain. In the evening a diffuse swelling of the left lower extremities was discovered, extending from the lower third of the thigh to the tips of the toes. The skin was thick, of a livid color; there was marked pitting on pressure, and at numerous points the sense of fluctuation could be detected. On the internal surface, just above the ankle, there was a large circular ulceration, the edges of which were irregular, and the base had a grayish color. There were a number of bullæ filled with blood-stained serum upon the lower third of the leg, and one very large one covering the entire dorsal surface of the foot. The right limb

was œdematous and pitted on pressure. Pulse, 120; respiration, 30; temperature, $101\frac{3}{10}^{\circ}$ F. Urine, yellow, cloudy, acid; specific gravity, 1012, and contained *seven* per cent. of albumen, hyaline and granular casts, but no sugar. Heart and lungs not examined, because of the great size and feebleness of the patient. Diagnosis, erysipelas of leg.

March 22, 1883.—About 9.30 A.M., as the doctor was going through the ward, pulse, 90; respiration, 22; temperature, 98.2° ; a few minutes later the doctor was summoned, but on arriving found the patient dead. *Autopsy*, sixteen hours after death. Body well nourished; rigor mortis well marked; lower extremities markedly œdematous. Woman very fat. Some discharge from vagina; pericardium normal. Heart: Ceased in diastole; tissue soft, fatty, and pale; cavities dilated; aorta showed commencing atheroma, otherwise healthy. All the valves normal. Right lung: Pigmented on surface, irregular congestion; œdema and congestion in posterior portion of lower lobe. Left lung: Pigmented on surface; one small thrombus in posterior part of lower lobe; œdematous and congested like the other. Abdominal cavity—spleen: Not enlarged; post-mortem softening. Right kidney: Two small and one large cyst at upper end; very fatty; cortex irregular and granular; capsule partially adherent. Left kidney: Large cyst, holding one-half ounce of clear fluid in lower portion of kidney, which occupied whole thickness of organ; large, irregularly congested; on section granular appearance of cortex; capsule as in the other. Liver: Small; on section fatty and softened, partly due to post-mortem change.

The uterus was enormously enlarged and contains numerous fibroids, the largest of which is evidently calcareous. One was distinctly intramural. The walls of the uterus were very much thinned, the inner surface was of a grayish color, and emitted an exceedingly offensive odor. Within the cavity were two or three small fibroids, only very slightly attached to the uterus, and undergoing the process of softening. The external os was small, probably would not admit the little finger. The uterus contained a little over one quart of very offensive pus.

The leg did not contain any pus at all, it was simply œdematous, and in the hasty examination made he did not discover any thrombi in the veins.

APOPLEXY—FATTY LIVER.

DR. ROBERT T. NEWMAN presented the liver removed from the body of a man who died suddenly May 12th. The patient, so long as he could recollect, had suffered from derangement of digestion. Ten years ago he had an apoplectic stroke, was unconscious for a few days, the mouth was drawn to one side, and he was paralyzed upon one side, but subsequently regained his intellectual faculties entirely, and also fully recovered his motion. About sixteen weeks ago he was again found unconscious, and it was supposed that he had had another apoplectic stroke. When Dr. Newman first saw him, his abdomen was immensely enlarged, but there was no evidence of accumulation of fluid. The patient's stools were clay-colored, he suffered from diarrhœa, his urine was loaded with bile, and parts of the body were slightly jaundiced. Percussion gave evidence of enlargement of the spleen. At that time Dr. Newman was not able to find any evidence of paralysis, although the patient was unable to move himself in bed. Defecation and micturition were voluntary. He died suddenly eight days afterward from what appeared to be, from the description given, an apoplectic stroke. During life, so far as auscultation and percussion went, the heart seemed to be normal; at the autopsy, only a very limited one being permitted, the liver was removed, and found on microscopical examination to be fatty. It was increased in size, the gall bladder was empty, and there seemed to be some stenosis of the common bile-duct.

DR. SATTERTHWAITE remarked that the liver seemed to be of the nutmeg variety, and apparently indicated that

there was some obstruction of either the cardiac or the pulmonary circulation; probably also there was some increase of connective tissue, as was usually the case with this lesion.

The Society then went into executive session.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, May 5, 1883.

JAMES B. HUNTER, M.D., PRESIDENT, IN THE CHAIR.

DR. BEVERLY ROBINSON presented a patient with

DEFLECTED NASAL SEPTUM—OBSTRUCTED BREATHING—
—ADENOID GROWTH IN THE LARYNX.

The patient was a young woman who had been suffering for a year and a half from obstruction in the left nostril, for which she had recently applied for treatment. There was a suspicion of her having had syphilis. The nasal septum was deflected to the left, so that the air could not be drawn through the nostril of that side. There was a small adenoid growth in the vault of the pharynx. The patient was considerably more deaf, to the ticking of a watch, in the right ear than in the left. The points of interest were, that despite the obstruction and the adenoid growth in the pharynx, the patient's voice was not at all affected, and that the ear affected was on the opposite side from the obstructed nostril with its deflected and ulcerated septum.

DR. SEXTON examined the drum-heads and found evidence of an old inflammatory change which had probably occurred some years before, when the patient had had an attack of scarlet fever.

DR. C. L. DANA read a paper entitled

THE NATURE AND TREATMENT OF CERTAIN FORMS OF
CHRONIC NERVE-WEAKNESS.

[The paper is published in full on p. 57 of THE RECORD.]

The paper being open for discussion Dr. H. F. WALKER said that he had used the fluid extract of coca considerably. He had found it to act far better with men than with women, a fact which he was inclined to attribute to the more extensive use of tea by women.

DR. HUNTER said that he had once imported some of the fresh leaves, having been told by gentlemen who had lived in South America that these alone were of any value. They had given good results.

DR. BEVERLY ROBINSON had used a good deal of the Mariani wine of coca, and thought that it had acted very satisfactorily. He happened to have met M. Mariani several years ago, and had been led to place confidence in the genuineness of his preparation.

The speaker had used

HYDROBROMIC ACID

in two conditions: that of vertigo, presumably from stomach trouble, and that of dyspepsia. Its use in stomachal vertigo he had taken from a suggestion by Woakes. He had employed the Fothergill solution.

DR. W. P. GIBNEY, referring to the

PROGNOSIS

in these conditions of nervous invalidism, asked if these patients ever got well. In his experience the cases were most untractable, and however one helped them they were apt to fall back to their former condition.

DR. DANA said that he had once been inclined to take a very gloomy view of the prognosis. He did not know that now he could recall cases of pronounced and long-standing neurassthenia proper which he was sure had permanently recovered. He thought the prognosis better, however, than Dr. Gibney was inclined to paint it. He believed that almost every patient could be greatly im-

proved and life made more comfortable to him. Some cases, undoubtedly, got well.

DR. KINNICUTT said that in his experience these cases do improve, and even become to all intents and purposes well, continuing so for several years. He thought, however, that there was always a tendency to relapse. A case in point had occurred in his experience recently.

DR. POLK said that he supposed the nature of the troubles that go under the name of neurasthenia had never been very definitely made out. He asked if anything of importance had been written on the subject aside from the work of Beard.

DR. GIBNEY said that it was the same old group of symptoms which had been known for a long time. In women we are apt to call it spinal irritation, in men nervous prostration. Some authorities called it hyperæmia, etc.

DR. DANA said that in the first part of his paper he had discussed this question and endeavored to throw some light upon it.

So far as the literature was concerned, the subject had been treated by Bouchut, of Paris, in a work entitled "Du Nervosisme," published in 1877, and by Möbius, of Leipzig, in a work entitled "Nervosität," published in 1882. Erb also discusses it, and of late years many German writers (Glax, Burkart, etc.) had been studying the special forms of neurasthenia.

The speaker thought it would be long before we knew the morbid anatomy or chemistry of nervousness and chronic nerve-weakness. We could speak, however, much more definitely about its morbid physiology, and he had ventured to make a contribution to that subject.

DR. SAMUEL SEXTON referred to a case where he had used coca with benefit. He had found it difficult to get patients to take large doses of hydrobromic acid on account of its powerfully acid taste.

DR. HUNTER said that with reference to those cases of nerve-prostration and hysteria which were submitted to the Weir-Mitchell treatment, he had observed that even in patients who were improved, the symptoms often returned soon after passing from the treatment.

ONTARIO MEDICAL ASSOCIATION.

Annual Meeting, held at Toronto, June 6 and 7, 1883.

(From our Canadian Correspondent.)

DR. J. E. GRAHAM, of Toronto, read an exhaustive paper on

THE BACILLI OF PHTHISIS.

The paper treated fully of the question in its present bearings to medical opinion. From a careful analysis of forty cases in Dr. Graham's own practice he concluded that the bacilli are constant in cases of true phthisis. In some cases where they are not found at first, repeated examinations would reveal them. The second point of importance in the paper was that its author leaned very much in favor of the view that phthisis is contagious. He strongly recommended antiseptic inhalations and everything which was of any real value in sustaining the powers of the system.

DR. J. FERGUSON remarked that of 2,509 cases, the statistics of which he had collected, the bacilli had been found in 2,417. Of the cases in which the bacilli had not been found sufficient care was not taken, as in many of these cases few examinations of the sputa were made. After making all due deductions for error there seemed to be some relationship between the numbers of the bacilli and activity of the disease. Further he believed that phthisis is really a contagious disease; but thought observers might be led into error for the following reasons: 1, Phthisis from its very nature would be likely to have a long incubation period, and thus the true source of infection might be overlooked in many cases; 2, that the germs seemed, from carefully conducted experiments,

to lose their vitality soon after their ejection from the body in which they were produced; 3, few germs are contained in the expired air, yet if this be concentrated and passed through a cage holding small animals these can be rendered tubercular in this way; and 4, in many cases these germs came in contact with persons of sufficient power to resist them, just as in the contagion of other diseases. With regard to treatment he held: 1, that rest was of great importance, as the lungs had not so much work to perform; 2, good nourishment of every kind; 3, elevation to a height of about 4,000 feet; 4, antiseptic inhalations, which ought to be kept up almost constantly; and 5, isolation of the patient from sleeping with others in the family, or too close intimacy.

DR. I. H. RICHARDSON agreed in the view that phthisis was possibly one of the most contagious class of diseases.

DR. BURT, of Paris, exhibited a patient who had been a very severe example of

TRAUMATIC TETANUS.

The wound from which the disease originated was on the lower front part of the forearm. He practised complete insulation of the forearm by a thorough dividing of the nerves supplying it. The patient made an excellent recovery.

DR. STRANGE, of Toronto, read a paper on

ACETONÆMIA.

He thought that the presence of acetones in the blood was the cause of the coma in diabetes. He referred to the hopelessness of diabetic coma, and expressed the desire that ere long we would be in a better position regarding treatment.

In the discussion that followed DR. J. FERGUSON held that the coma was not due to acetones in the blood, and further that the acetones did not depend upon the sugar condition of the urine for its existence in the system. Jaksch, of Vienna, has found acetones to exist in the blood in febrile states of the body, in cases of carcinoma, and in hydrophobia. Frerichs, of Berlin, from an examination of four hundred cases, concludes that, 1, the nerve-centres are not the real cause of the coma; 2, that the changes in the blood do not sufficiently explain it; 3, that uræmia is not the cause, as coma is found without uræmia; 4, that fat emboli is not the cause, for in some cases of coma no evidence whatever existed to show that emboli had anything to do with the trouble; and 5, that acetonæmia is not the cause of the coma. Frerichs regards the necrotic changes in the kidneys as the real cause of the coma.

DR. J. FERGUSON read a paper on

THE LIGAMENTUM TERES IN ITS RELATION TO HIP-JOINT DISEASE.

He showed that the ligament prevented undue rotation of the leg outward; and secondly, that if of normal length it prevented the femur coming in contact with the acetabulum. In a normal hip-joint there is a slight interval between the femur and the os innominatum. Thus the pelvis is suspended from the thigh bones by the round ligaments. Should these ligaments be lengthened or ruptured from jumping or wrestling severe trouble may ensue. He gave an instance of a case where hip-joint disease was in its early stage. The boy had been greatly addicted to jumping from high places. The patient died of pneumonia; on a careful dissection of the joint the round ligament on the affected side was found slightly ruptured and lengthened, permitting the head of the femur and the acetabulum to come into close apposition.

DR. MCPHEDRAN showed

A CASE OF TRUE PRURIGO.

which he was treating with very good results by the hypodermic injections of nitrate of pilocarpine. As much as one-grain doses had to be given before diaphoresis could be produced.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

CHOLERA IN EGYPT—THE HARVEIAN ORATION BY DR. HABERSHON—MEDICINE AND RELIGION—THE SUMMER SESSION—THE COMING ELECTION AT THE COLLEGE OF SURGEONS.

LONDON, June 30, 1883.

SOME alarm has been caused by the report that an outbreak of cholera has occurred in Egypt. Later intelligence seems to show that many of the cases are rather cases of typhoid, and that no genuine epidemic of Asiatic cholera has taken place.

The Harveian Oration at the College of Physicians for this year was delivered on Wednesday last, 27th inst., by Dr. Habershon. After referring to the successive discoveries made by physiologists in different ages, Dr. Habershon spoke of Darwin and struck a different note to most of his predecessors when he maintained that though Darwin's facts are true, his deductions are not. Dr. Habershon is not alone in this. Many distinguished scientists do not accept Darwin's deductions as necessarily true. It is in fact but a theory. One of our weekly journals has, however, seen fit to call Dr. Habershon to account for his statements and also because his oration had a religious bearing. It is unfortunate that paragraphs of this description should promote the idea—already too prevalent amongst the public—that medical men as a body are opposed to religion. This popular fallacy is very widespread and at times gives rise to curious statements. Not long ago I heard a gentleman state that he only knew two medical men who took any interest in religious matters, although he was in a position which brought him in immediate contact with a large number of the prominent practitioners of London. A gentleman who was present at the time, immediately corrected him by naming half a dozen others, amongst whom was Dr. Habershon, long well-known for his activity in this direction. It is not long since Dr. Lauder Brunton produced a volume on "Religion and Science," and Dr. Mortimer Granville—who not long ago was conducting *The Lancet*—has just produced a volume on "Some Difficulties of Belief." Perhaps a more important example is that of the work done by Dr. Chance, who, on account of his great Hebrew scholarship, is serving as a member of the company of the revisers of the Old Testament.

The summer session is now drawing to a close, and doctors as well as their patients are discussing the great question where to go? Another indication of the season is seen in the publishers' lists, where books on spas are numerous. Within the last few days several books of this description have appeared.

The coming election (next week) of two Fellows to seats in the Council in the College of Surgeons promises to be an exciting one. The candidates are fairly equal as to merit, but the question of allowing country Fellows to vote by proxy or by voting papers is a burning one and will probably decide the election. The Association of Fellows of the College of Surgeons has brought pressure on the candidates to elicit their views on this important question. The justice of the demand made by the provincial Fellows seems self-evident.

SEA-SICKNESS AND ITS TREATMENT.—Dr. G. L. Walton, in an article on this subject (*Boston Medical and Surgical Journal*), argues against the value of bromide of sodium as recommended by Beard. In brief, his view is that in small doses the bromide is useless, in large doses it may be dangerous. The author brings very little evidence to illustrate his views and quite ignores the very large number of cases where the bromide does give vast relief.

THE INTERNES OF THE HOSPITALS—DO THEY DERIVE AS MUCH BENEFIT FROM THE SERVICE AS THEY SHOULD?

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The clinical advantages given to the medical student of this city are inadequate, and not in proportion to the immense amount of clinical material at hand.

There is seldom a time in the course of his college life when a student without special advantages can get the opportunity of examining a case of disease at his leisure after it has been demonstrated by the professor in charge. Take for example a medical clinic. There are perhaps sixty or eighty students seated at various distances from the pit. A patient is brought in, the professor asks his questions, makes his diagnosis, outlines the treatment, and the case is sent out. There is usually no time for the students to ask questions or to examine the case for themselves. The case passes from their view, and they, if at all skeptical, do not feel sure that the diagnosis is correct. No explanation is given as to why certain remedies are given in preference to others just as efficacious. In my mind, it would certainly be of greater advantage to the student to have one case thoroughly explained to him, giving the why and wherefore of questions asked and drugs prescribed, and then allowing him to examine the patient. Under the present arrangement it is perfectly possible, as was some time ago stated in one of our journals, for a student to pass three years at a medical college and graduate without having been near or questioned a single sick person.

The question I wish to ask, is this: "If the clinical advantages of the college student are so slight, do the Internes of our hospitals receive as much advantage from their positions (won by hard work) as they have a right to expect? I do not think they do. In such a matter a great deal depends on the character of the interne. But leaving that out of consideration, I ask, "Do the attending physicians and surgeons give their staff as much clinical instruction as they should? I think all who have experience in such matters will agree with me that they do not. The clinical advantages of the hospitals are very great, and in some of them they are taken advantage of to a limited extent. But in how many of them is it customary for the attending physician or surgeon to give the staff regular clinical instruction? It is certainly a rare thing to have a short lecture delivered on an ordinary case during the daily rounds with the attending physician. It does not seem to occur to the majority of them that it is their duty to give such instruction as often as it is possible. It is true that once in a while a few remarks are made on a case which is interesting either on account of its rarity or its severity. But such things are of no practical value to the young man just starting out in practice.

All ordinary cases are dismissed with a few words and their treatment is relegated to the gentleman at the head of the staff.

And how often is such a young man capable of treating the majority of cases unless he have received previous instruction from some one of experience? Because a person is intelligent and has a mind well stored with facts, it does not follow that he can apply these facts to the best advantage without a certain amount of guidance. But there is another side to the matter of instructing the staff. It is their duty to at least appear to enjoy and appreciate whatever it may please the attending physician to tell them.

One cannot expect a teacher to persevere long if his audience plainly show that they are bored. This is a trait more often found in the junior members of the staff. They are very apt to think that they know everything worth knowing and that it is hardly worth while to take up their time telling them things of apparently so trifling importance. These are the men who, after they have been in the routine of practice for a few years, regret the neglect of such advantage in the past.

Even the nurses in our training schools receive instruction in matters in which every physician should be proficient, but in which no instruction is given.

I refer to making and applying poultices, fomentations, stupes, blisters, in giving sponge-baths without endangering the patient's condition. No instruction is given in cupping and leeching. Where is there a young physician who can show their patients' friends or relatives how to change a sheet so as to disturb the patient the least? It may be said that the physicians of this city do not need to know such things. This may be true in a measure, but not all people, even in large cities, can afford to have a trained nurse to do them.

But the majority of physicians, graduates of the city colleges, are scattered over the South and West, and a country practitioner who cannot show his country nurses how to do these things is certainly wanting in his duties toward his patients.

Such things, trifling as they may seem, are practically of more importance to the country practitioner than a thorough knowledge of pathological appearances at autopsy. For, how often is a post-mortem examination made in the country? Hospital men, at least, should know how to do all these things.

Instruction in giving anæsthetics is practically unknown in this city, strange as it may seem. In hospitals the junior-assistant usually administers the anæsthetic. He may or may not have given it before entering the hospital. He has usually never seen it given except perhaps in the amphitheatre. He has not the remotest idea what symptoms indicate danger, but he gradually gains this by a sad experience. Under the present system there is great danger to the patient and a great waste of time and anæsthetics. I think all operating surgeons will agree with the assertion that ether and chloroform should be administered by a person specially trained and appointed for that purpose, or at least by the senior assistant, who has had six months in which to learn something about it in a practical way.

Respectfully,

AN EX-RESIDENT.

MEDICAL ADVERTISEMENTS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The criticisms of THE RECORD upon the practice of religious journals publishing advertisements of secret medicines prompted me to write to the managers of the Western Methodist Book Concern, Cincinnati, O., in regard to the loss to the income of their publications which they have sustained by their refusing to publish medical advertisements of any kind. There are published by this concern four papers, viz., *The Western Christian Advocate*, Cincinnati, O.; *Northwestern Christian Advocate*, Chicago; *Central Christian Advocate*, St. Louis, and *Christian Apologist*, Cincinnati, O. From all of these papers such advertisements have been excluded for three years. In answer to my inquiry they state that they lose annually several thousand dollars, and that during the week that my letter was received they refused such an advertisement, for the publishing of which they were offered one thousand dollars. They add, furthermore, that to exclude such advertisements does not pay financially. Be it said, though, to their credit, the present management have no idea of departing from their present course. I only send you this item to show that to the rule there are some exceptions. It is to be hoped that the example of the few religious papers that refuse to advertise a disreputable business, will be followed by others. And once these journals practise consistency, a great check will be put upon the actions of those ministers who so flippantly endorse such medicines. Evidently there is a brighter day dawning for the honorable practice of medicine, and since, as a profession, we are trying to educate the laity

above a belief in faith cures, patent medicines, etc., is it anything more than just that we should ourselves flee from the very appearance of evil?

Please allow me a few questions and thoughts upon the subject of medical advertisements in our own journals. Is it not a fact that to the readers of medical journals it has become almost obnoxious to see upon every page, and often half a dozen times on a page, such as this, "Beware of imitations." "Specify our make," and scores of other such admonitions? As though one were upon the brink of ruin and did not know it. Then the list of adjectives which appear in our advertisements compare favorably as expressing superlative worth with the laudations of the patent medicine vender. Do we not condemn patent medicines because they are advertised to cure almost every disease? And yet if we believe our own advertisers I can cure nearly all of the ills that flesh is heir to, with a few samples of mineral water, for instance, conditional only, as one professor says in his advertisement, "that it be taken in time." Can we with consistency, as long as we permit such things in our journals, say to the patent medicine advertisement in the religious paper, "Out, damned spot?" If these things are objectionable would not the manufacturers remedy the evil if the publishers declined to publish these advertisements? I would not presume to speak for any one else, but I would order A.'s pills just as often if he did not in his advertisement tell me in every other line to do so, and I would have as much confidence in their efficacy if a certain doctor had not said, "They are incomparably the best."

Please say to the manufacturer who is inclined to be exuberant in his praises of his goods, and to the physician who is already great enough to not need to advertise himself by thus publishing what may be nothing more than the pleasant effects of a good dinner—say to them, in the language of the boy upon the street, even though his language may not be strictly æsthetic, "Give us a rest."

T.

MILLBURY, O.

"A RARE CASE INDEED."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: An article under this title in the July number of THE MEDICAL RECORD, page 16, gives a case of extrusion of a foetus after burial of the mother; and the commentator offers as a reason for this unusual occurrence either that the woman was buried in a state of suspended animation or that the foetus was extruded immediately after death, leaving us to infer that uterine contraction is necessary to expel a foetus. In legal medicine this interesting subject has received much attention, and perhaps the best remarks upon it are to be found in "Tidy," vol. i., pages 71-72 (Wm. Wood & Co.): "It is important to note that the development of gases in the body has been known to produce certain effects closely simulating vital acts. Probably gaseous distention is the usual cause of the occasional movements of a corpse, such as its turning on the side after it has been 'settled' in the coffin. Again, it is recorded that the pressure of the gases generated in the abdomen has been sufficient to force feces from the bowels, urine from the bladder, and even a foetus from the uterus (Case 73). Dr. Aveling records a series of six cases collected from medical literature, where delivery is said to have occurred spontaneously after death. In one of the cases it is stated that the child was born alive. It is certain that, as a rule, this spontaneous post-mortem delivery results from the pressure exerted by the gases developed in the abdominal cavity, although another explanation of this unusual occurrence has been suggested."

"Tidy" here refers to the theory of post-mortem contractions of the uterus.

The author also refers to a case of inversion of the unimpregnated uterus from the pressure of gases devel-

oped after death in the abdominal cavity. It is perhaps hardly necessary to add that the development of gases of decomposition may be very great within a few hours after death.

I am, sir, etc.,

W. H. TAYLOR, M.D.

NEW BEDFORD, MASS.

HOT WATER IN THE TREATMENT OF INFLAMMATION OF MUCOUS MEMBRANES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In your issue of June 16th, you quote, from the *Medical Age*, Dr. Ritzy's method of treating throat troubles with hot-water gargles. I have used hot water as a gargle for the past six or eight years, having been led to do so from seeing its beneficial effects in gynecology.

In acute pharyngitis and tonsillitis, if properly used at the commencement of the attack, it constitutes one of our most effective remedies, being frequently promptly curative. If used later in the disease, or in chronic cases, it is always beneficial, though perhaps not so immediately curative. To be of service it should be used in considerable quantity (a half pint or pint) at a time, and *just as hot* as the throat will tolerate. I have seen many cases of acute disease thus aborted and can commend the method with great confidence.

I believe it may be taken as an established fact, that in the treatment of inflammations generally, and those of the mucous membranes in particular, moist heat is of service, and in most cases hot water is preferable to steam.

All are familiar with its use in ophthalmia and conjunctivitis, as also in inflammations of the external and middle ear, and I feel confident that those who employ it for that most annoying of all slight troubles to prescribe for, viz.: a cold in the head, or acute coryza, will seldom think of using the irritating drugs mentioned in the books, nor of inducing complete anæsthesia with chloroform in preference to the hot-water douche. It is important to recollect, however, that to be effective in aborting this disease, it must be employed during the first stage of hyperæmia.

Nor is the urethral mucous membrane any exception to the general rule. Cases of urethritis and gonorrhœa are benefited or cured by its use when applied at the commencement of the inflammation. In the cure of gleet, I know of no other agent so often serviceable. Where there is no stricture, almost any case of gleet will yield in a short time to the use of the hot-water douche followed by mild astringents.

Keep in mind the principle of its curative action, viz.: the removal of hyperæmia, and the local sedative influence, and there will be found few cases of inflammation of mucous membranes where it will not, at some stage of the disease, promote a cure.

GEORGE R. SHEPHERD, M.D.

HARTFORD, CONN., July 12, 1883.

THE ANTI-VIVISECTION AGITATION.—A recent number of the *Contemporary Review* contains an article on the anti-vivisection agitation by the celebrated physiologist, Dr. E. DeCyon, and a reply by Mr. Hutton. The former gives several examples of wholly dishonest use made by the anti-vivisectionists of England of diagrams and garbled or distorted sentences from his "Physiologische Methodik." Of course that was to be expected, but it makes the deed none the less disgraceful. When a party profess to be actuated by such high and lofty humane views as do these agitators, it certainly is most contemptible that they should use such dishonest means to prejudice the community. Cyon also shows that of the two German leaders against vivisection one knew absolutely nothing about the subject, and the other was actually insane, as is now known, when he attacked physiological experimentation so bitterly.—*Weekly Medical Review*.

New Instruments.

PREMATURE DELIVERY FORCEPS.

By STOYELL C. PARSONS, M.S., M.D.,

ATTENDING SURGEON TO NORTHEASTERN DISPENSARY, DEPARTMENT DISEASES OF WOMEN.

On several occasions, having to use forceps in premature delivery, with the misfortune of having the instrument slip off four to six times during the necessary manipulation, I thought it necessary to try and overcome the difficulty if possible, and after a successful experience of three cases with my forceps, as illustrated by accompanying woodcut, I think I have accomplished my object.

Dr. Brickel's, being about the only one of any merit, are excellent where the head is in the inferior strait, but in the superior they are at times applied with great difficulty on account of the handles being comparatively straight or without the pelvic or cradle curve, as used by

Dr. Sawyer, of Chicago. On being applied and tension made, the power is exerted in the line of the axis of the superior plane, thus forcing the head against the pubis and retarding instead of aiding delivery. As before stated, tension being made, the blades do not hold securely on account of their having a slight outward flare at the tip, thus weakening them where the greatest power of assistance is required. To obviate these difficulties, I have continued the original curve of the fenestra inward to the tip so that the power of resistance is equal throughout the entire blade, and the head once fairly inserted within it, it is impossible for it to slip, except by breaking or bending in consequence of poor material. The handles I give the cradle or pelvic curve, thus enabling the operator to introduce the same with less difficulty and exert all tension or force in the line of the axis of the pelvic canal. My thanks are due to Messrs. Shepard & Dudley, 150 William Street, New York, for their kindness in furnishing designs.

The forceps weigh two hundred and forty-two grammes and are illustrated by the accompanying cut, which is executed one-fourth scale.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 7, 1883, to July 14, 1883.

BAILY, E. I., Colonel and Surgeon. In addition to his present duties to take charge of the office of Medical Director, Military Division of the Pacific, during the absence of the Medical Director. S. O. 64, par. 2, Military Division of the Pacific, June 30, 1883.

SUTHERLAND, C., Colonel and Surgeon, Medical Director, Military Division of the Pacific. Granted leave of absence for one month with permission to apply to the Adjutant General of the Army for extension of two months. S. O. 64, par. 1, Military Division of the Pacific, June 30, 1883.

CAMPBELL, JOHN, Lieutenant-Colonel and Surgeon. Medical Director Department of the South. Leave of absence on surgeon's certificate of disability granted by S. O. 50, Department of the South, May 21, 1883, extended one month on surgeon's certificate of disability, with permission to leave the Department of the South. S. O. 156, par. 7, A. G. O., July 9, 1883.

PERLEY, HARRY O., Captain and Assistant Surgeon. Assigned to duty at Fort Pembina, D. T. S. O. 118, par. 1, Department of Dakota, July 5, 1883.

Official List of Changes in the Medical Corps of the Navy for the week ending July 14, 1883.

GREEN, E. H., Past Assistant Surgeon, granted leave of absence for one month.

GRIFFITH, S. H., Past Assistant Surgeon, granted leave of absence for one month.

HUDSON, A., Medical Inspector, Assistant to Bureau of Medicine and Surgery, granted leave of absence for one month.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending July 14, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
July 10, 1883.....	1	13	42	4	81	20	0	0
July 17, 1883.....	0	18	38	4	68	23	0	0
<i>Deaths.</i>								
July 10, 1883.....	1	6	12	4	19	13	0	0
July 17, 1883.....	1	10	7	4	21	16	0	0

MEDICAL PRACTICE IN ENGLAND.—The *Student's Journal* says: "There are great complaints in professional circles, both East and West, as to the scarcity of money. I hear that many of the West End physicians find their incomes this year very seriously reduced in consequence of the general depression in trade and the straitened circumstances of many of the landed proprietors of the country. Every one is obliged to be content with smaller fees, and unfortunately there are fewer of them."

AN ANÆSTHETIST is the latest medical title. It has been bestowed upon a medical officer of the Chelsea Hospital. An anæsthetist may be described as a person who excites no feeling.

THE TRICHINÆ IN CHICAGO PORK.—In the present agitation over trichinous pork and adulterated lard, the investigations made some years ago by Dr. W. T. Belkfield, and Mr. H. F. Atwood, of Chicago, may be cited. They examined the pork in the various packing-houses of that city, and found trichinæ present in eight per cent. of the specimens, the parasites averaging about 20,000 to the cubic inch. These gentlemen believe that infection of human beings with trichinæ is very much more common and less injurious than is commonly supposed. They have made the interesting discovery that a small portion of sulphurous acid dissolved in the brine in which hams are pickled will kill all the trichinæ.

NERVOUS CONSTIPATION.—In nervous constipation the *Rivista di Bologna* recommends the following pill:

R. Pulv. ferri sulphatis 0.10 (gr. 1½)
Aloës soccotrinæ..... 0.05 (gr. ¾)
Ext. belladonnæ..... 0.005-0.01 (gr. 1/3-1/6)

From one to four of such pills may be taken during the day. Should intestinal atony be suspected, the extract of belladonna is to be replaced by ext. nucis vomicæ, 0.005-0.01 (gr. 1/3-1/6).

SUICIDE IN EUROPE.—According to Legoyt, the number of suicides to each million inhabitants in the various

countries of Europe is as follows: Germany, 261; Denmark, 257; Switzerland, 215; France, 160; Austria, 121; Belgium, 87; England, 69; Holland, 45; Russia, 30; Italy, 37 (27?); Ireland, 21; Spain, 17. In almost all of these countries suicide by strangulation is preferred. In Germany, of 100 cases of suicide, 64 were cases of strangulation; in Austria, 47; in Hungary, 60; in Denmark, 77; in Russia, 73. Second in favor of strangulation stands drowning, a method, however, practised less in France than elsewhere. Poisoning is not employed much except in Ireland and Italy. Suicide by means of the gas from charcoal occurs more frequently in proportion in France, and especially in Paris, than elsewhere.—*Gior. Int. delle Scienze Med.*

WINTER AT CATANIA.—The advantages of Catania as a winter resort have as yet received but little attention, although the climate is by medical climatologists claimed to be one of the finest. Dr. Ughetti recommends the place on account of its uniform temperature (mean for the year, 18.5°, mean for the winter, 13.1°), with its slight and graded oscillations, its freedom from winds, and because of the number of serene days without rain, fog, or snow. The atmospheric pressure also varies but little (from 768 to 750).—*Gior. della Soc. It. d'Igiene.*

THE PHYSIOLOGY OF SLEEP.—M. Vulpian in his lectures upon the vaso-motor system seems to have demonstrated that the present popular theory of cerebral anæmia causing sleep is not correct. He argues first that insomnia is a frequent attendant of general anæmic conditions. The idea that drowsiness after meals is caused by derivation of blood to the stomach and intestines is disproved, he says, by looking at the turgid countenance and throbbing temporals of the sleeping gourmand. Vulpian was never able to produce sleep by compressing or ligating arteries that supply the encephalon, nor by galvanizing the cervical sympathetic, and thus producing cerebral anæmia. He examined the membranes of the brain of numerous animals whom he had placed under anæsthetics or hypnotics. In none of them was there any notable change in the vascular supply. He concludes that the vascular supply has nothing to do with the causation of sleep; that any slight anæmia which may accompany this condition is a result, not a cause. M. Vulpian furnishes no substitute for the theory he destroys. He simply considers sleep to be a *habit* of the nervous system of relapsing into a state of torpor.

The most generally accepted theory now is probably that of Prof. Preyer.

THE DEATH OF THE REV. CHAS. W. CALHOUN, M.D.—Rev. Charles W. Calhoun, M.D., a medical missionary of the Presbyterian Church, stationed at Tripoli, Syria, died about three weeks since at Shevcifat, Mt. Lebanon. He was the only son of the late Rev. Dr. S. H. Calhoun, and was educated at Williams College, Union Theological Seminary, and Bellevue Medical College. He was a native of Syria and an intimate acquaintance with the Arabic tongue gave him easy access to the hearts and homes of the people. About a year since he was subjected to a series of vexatious persecutions from the Turkish authorities at Tripoli, and since then he has spent most of his time travelling among the villages. One of the insults heaped on him was the removal of the sign on his office. The American Minister at Constantinople, Gen. Wallace, was requested to demand redress for this act from the Turkish Government, and almost at the same time with the news of his death came a telegram stating that an apology had been demanded.

HABITUAL CONSTIPATION.—In the *British Medical Journal* Dr. J. Mortimer Granville offers three prescriptions which he claims are generally applicable to the treatment of all the well-recognized forms of habitual constipation. He sees three forms of the disease, one due to deficient peristaltic action, one due to deficient

glandular secretion, and one due to interruption of the habit of periodic evacuation. For the relief of the first form he prescribes:

R. Sodæ valerianatis..... gr. xxxvj.
Tincturæ nucis vomicæ..... ℥. lx.
Tincturæ capsici..... ℥. xlvij.
Syrupi aurantii..... ℥. iss.
Aqua..... ad ℥. vi.

M. Ft. mistura. Sig.—Tablespoonful in water half an hour before meals.

For the second form:

R. Aluminis..... 3 iij.
Tincturæ quassiae..... 3 j.
Infusi quassiae..... 3 vij.

M. Sig.—Dessertspoonful after meals.

For the third form:

R. Ammonia carbonati..... 1 j.
Tincturæ valerianæ..... 1 j.
Aque camphoræ..... 3 v.

M. Sig.—Take ounce as directed on arising from bed.

Dr. Granville insists upon a regular hour for going to stool, at least to make an effort at evacuation. He proposes to establish in this way the normal habit, and thinks aperients in habitual constipation do no good. One naturally inquires, when reading the above, what is to be done if two or even all three of these forms are united.

FACTS FOR OUR RELIGIOUS WEEKLIES.—Prof. A. B. Prescott says that the use of patent medicines without a knowledge of their composition does injury to the health of the people, for the following reasons: 1, they may, and in fact sometimes do, contain powerful or poisonous articles unsuspected; 2, they always may be, and often are, inert, and become a false reliance to the neglect of other and due measures in the care of health; 3, they are liable to be changed in composition, so that any experience of their effects as they are purchased at one time is not conclusive as to the same named articles purchased another time; 4, it is submitting health to the treatment of a distant and irresponsible stranger, and learning to hazard health in an apparent game of chance; 5, they are trusted to act as antidotes to disease in the sense in which no medicines can antidote disease; 6, they favor excessive recourse to medication and thereby increase the resort to physicians.

THE TREATMENT OF ACUTE GOITRE WITH THE BINODIDE OF MERCURY.—Dr. Mouat, of Bengal, was the first to notice specially the value of the use of biniodide of mercury in combination with the rays of the sun in the cure of goitre. His practice was to use the mercury as an ointment of three drachms to a pound of lard; a portion was rubbed in an hour after sunrise, the patient afterward sitting with his goitre well exposed to the sun as long as he could endure it. After this a fresh layer of ointment was carefully applied, and in ordinary cases a single application was sufficient. Of the value of this treatment in India there can be no question. Surgeon-Major Albert A. Gore, reports (*Dublin Journal of Medical Science*) thirty cases which he successfully treated in this way.

PROFESSORSHIPS AT CAMBRIDGE.—Dr. Michael Foster has been elected to the newly established Chair of Physiology, at Cambridge. Dr. Alexander Macalister, of Dublin, was elected to the Chair of Anatomy, and Professor Humphrey has been appointed to the Chair of Surgery.

IN PHTHISIS AND BRONCHITIS, Renzi and Rimmio report good results from the inhalation by spray of iodoform dissolved in turpentine.

PHENORESORCIN is the name of a mixture composed of carbolic acid sixty-seven per cent, and resorcin thirty-three per cent. The addition of ten per cent. of water makes a fluid which can be diluted p. r. n., making a powerful antiseptic wash.

SOMETHING WORTH FIGHTING FOR.—A State board of examiners, the greatest need of the medical profession in the State of New York—a “mixed board” the only efficient one attainable under present conditions.—*Buffalo Medical and Surgical Journal*.

THE POISONOUS PROPERTIES OF THE CASTOR BEAN.—Dr. R. S. Harden, of Waverly, N. Y., writes: “Upon reading the account of poisoning from eating castor beans, in THE MEDICAL RECORD of June 30, 1883, I was reminded of my own (personal) experience with the bean. While a medical student at Bellevue in 1872, our professor of materia medica, Dr. McCready, picked a handful of the beans while passing through the hospital grounds and during his lecture upon cathartics he passed them around among the class, facetiously remarking that if any of us were in need of physic we could eat some of them. Not requiring a cathartic, but simply out of curiosity, I ate one bean, the results were very surprising and alarming. I vomited and purged violently all night, and purged during most of the next day, being so extremely prostrated that I was very much alarmed for fear of a fatal termination of my experience with the professor's innocent castor beans.”

OUR ALARMIST CONTEMPORARY, *The Lancet*, makes the extraordinary statement that “it would be difficult to imagine a more powerful apparatus for conveying disease than a book.” Our esteemed but over-earnest contemporary goes on to picture the circulating library as a chamber of insuppressible horrors, and borrowed books as containing the promise and potency of the most deadly contagions. The question follows, Is it better to live illiterate or die of the measles, whooping-cough, chicken-pox, mumps and all the other ills to which flesh is heir, and circulating libraries are testators to? If the *Lancet* had only taken the trouble to give its alarmed imagination a rest, and had consulted some of the facts, it would have found that the question of contagion by books has been carefully studied, in this country at least, and very little made out of it. The *Lancet* has got into a condition of sanitary erethism, and is bound to make its readers uncomfortable. We are reminded of *Punch's* verses, which might very well be directed against

“THAT DREADFUL JOURNAL.”

“It warns us in eating, it warns us in drinking,
It warns us in reading, and writing, and thinking;
It warns us in foot-ball, foot-race, eight-oar “stroking,”
It warns us in dancing and cigarette smoking;
It warns us in wearing red socks and shampooing.
It warns us in taking champagne and canoeing,
It warns us of drains in our snug country quarters,
It warns us of fever in mineral waters,
It warns us in everything mortal may mention,
But—what gives rise
To but little surprise,
Nobody pays it the slightest attention.”

The last is certainly wrong, as regards our valuable contemporary, however, since its views are always widely quoted, being always forcibly put forth.

IN PRURITUS OF THE GENITAL ORGANS, Scavenzio recommends local hypodermic injections of morphine.

BEER IN THE PARIS HOSPITALS.—The *Progrès Médical* (June 9) criticises a rather arbitrary circular which M. Quentin, the Director of the Assistance Publique, has just issued to the directors of the Paris hospitals, with instructions to communicate it to the medical officers. In this he declares that the consumption of beer in the hospitals has for some time past so increased as to become a very serious charge upon the budget and deranging its equilibrium. This abuse, as he terms it, he can no longer permit, for beer he declares to be neither a food nor a medicinal agent, and therefore it must from this date cease to be furnished as one of the current articles of diet, and only become procurable by means of exceptional prescriptions of the *chefs de service* under the surveillance of the Central Administration. The *Progrès* disputes the assertion that beer is neither food nor medi-

cine, and states that the medical officers find it of great value in the treatment of disease, and regards it as somewhat surprising that the Director should have issued this decree (which really means almost entirely stopping the use of beer) merely for economical reasons, without consulting the medical body as to its propriety. If economy is the object in view, there is said to be ample means of accomplishing it in the hospital administration, which is far too numerous. The hospital physicians have also signed a protest against the withdrawal of the beer. Nevertheless, it is abundantly demonstrated in America that beer is not an essential to a diet list of a hospital.

SUCCESSFUL OPERATION FOR STRANGULATED INGUINAL HERNIA ON A MAN EIGHTY-ONE YEARS OLD.—Dr. H. S. Hendee, of Louisville, N. Y., writes: "On June 6th I was called to an adjoining town to visit a well-known citizen, Mr. A. A—. Found him suffering from strangulated hernia, and had been in that condition for fifty hours. At once attempted its reduction, but failed. Gave chloroform, with the hope that under its influence parts might relax and reduction follow, but with the intention if reduction failed, to operate. Dr. C. P. Kirby of this place was called, and gave efficient aid. After making proper, but ineffectual efforts to reduce the hernia, the operation was at once commenced. The opening was made to the bowels and ring, with very little loss of blood, not exceeding half an ounce. The bowel was highly discolored. Dividing the ring was but a moment's work. The bowel was carefully sponged and returned to its place. Three deep ligatures united the wound. Carbolic acid lotions were applied; morphine internally. By June 20th the patient was practically well. The points which make this case worthy of note are, first, the age; second, the time which elapsed after the strangulation and before the operation. showing, as it does, that age and lapse of time need not deter the surgeon from making the operation."■

POLITICS AND MEDICINE.—The Dayton, O., Board of Health has discharged the Health Officer, Dr. Thos. L. Neal, and appointed a vigorous Democrat, Dr. A. H. Iddings, in his place. The Dayton *Journal* adds that "it was the deliberate opinion of the Board that the sanitary condition of their party demanded a Democratic doctor."

THE AMERICAN MEDICAL MAN ABROAD, AND HOW HE IS REGARDED.—A correspondent of the *Cincinnati Lancet and Clinic* writes home regarding the status of American medicine abroad, giving perhaps a rather one-sided view of it. He says: "They know one thing at least, and that is that medical diplomas can be bought in our country, and that almost every American has one of them concealed somewhere in his inside vest-pocket. 'How are the *Doctors Philadelphia* progressing?' I heard one of them remark to a friend of mine the other day. 'Finely,' he said, 'the American Government issues them to us as passports, and they thus serve as an easy means of identification, besides serving as a medical diploma.' 'You don't say so,' he replied, and probably went off to communicate the fact to Bismarck. They get the idea that bushel loads of these bogus medical diplomas, or D. P. (Doctor Philadelphiae), as they call them, are sold to the highest bidder, that most of our colleges engage in traffic with them by the fact that these quack professors advertise their institutions in the German papers, probably intending to attract the back-door German candidates to our shores. No wonder their faith in our colleges is shaken somewhat; no wonder they look with suspicious eye on the title of M.D. (*Genus Americanus*). Here is another sample of their thoughts. One of the most celebrated gynecologists of this city thus addressed the class one morning: 'Gentlemen, I present you a case of abortion of not unfrequent occurrence in this part of the country, our American neighbors, however, annually have six thousand

abortions, besides a large number that never reach publicity.' The German students look amazed and surprised, and if perchance an American is present, he is eyed to see how an abortionist looks. Is the medical profession in America so steeped in wickedness that a German professor allows his students to infer that every practitioner practises abortions, and that it is just as common a thing to have an abortion as a broken leg or a case of tuberculosis, for instance?

ANOTHER CASE OF TRANSPOSITION OF VISCERA.—Dr. G. Frank Lydston, of Chicago, sends us the following account of a case of transposed viscera: "J. M—, twenty-four years of age, barber by occupation, consulted me a short time since with reference to a slight attack of bronchitis, and stated casually that his heart was 'on the wrong side.' On examination, I found that his statement was correct. The heart occupies precisely the same relative position upon the right side that it ordinarily does upon the left, the apex being in the right fifth intercostal space. There are no evidences of cardiac hypertrophy, and the valves are apparently perfectly normal. The chest is perfectly symmetrical, there being no more than the normal disparity of measurement of the two sides. The lungs are normal, and no causes of cardiac displacement involving either an increase of weight or extraneous pressure are present. No dyspnoea is complained of, and the patient is to all appearances in perfect health. At my first examination, he had just climbed several flights of stairs, in preference to waiting for the elevator, but was not at all inconvenienced thereby. The abdominal viscera are in their normal positions, a point to which I will call especial attention, inasmuch as such cases are usually accompanied by a transposition of the liver and spleen. Niemeyer states that in dextro-cardia the liver usually occupies the left hypochondrium and the spleen the right. Taking the various features of the case into consideration, I think we are warranted in the conclusion that it is an instance of a quite rare anomaly, 'congenital dextro-cardia.' Pathological displacements of the heart are, of course, not infrequently seen, as the heart is a very movable organ, and slight causes may suffice to displace it, but the present case is certainly quite rare."

SIR JOHN HILL AGAIN.—A correspondent informs us somewhat dogmatically that the epigram on Sir John Hill, quoted by us recently, was not written by Garrick, but by Samuel Foote. Our authority was that of Mr. John Timbs, and we shall have to abide by it until a better is given.

Sir John Hill was one of the quasi-charlatans of the eighteenth century, a man of immense ability and industry, but of a waspish temper and irrepressible impudence. He was consequently the victim of many epigrams. A "Hilliad" was even written, in which Sir John was described as

"A wretch devoid of sense and grace,
The insolvent tenant of unnumbered space."

Another witty individual, who had been called "a wooden-headed booby" by the distinguished doctor, retorted with the following verse:

"The worst that we wish thee for all thy vile crimes,
Is to take thy own physic and read thy own rhymes."

Some other friendly poet caught up the last and wrote the following:

"No! let the order be reversed,
Or else unlash his crimes;
For if he takes his physic first
He'll never read his rhymes."

THE REWARD OF A GOOD ACTION.—Those who do not believe in a readjusting hereafter should read the story of the good doctor of Lyons: As Dr. Monnet, the good man referred to, was passing along the streets one cold day last January, he saw a drunken man fall down and seriously injure himself. The benevolent physician hurried to the fallen and stupefied man, helped him up, and

led him to a neighboring drug store, where he bound up his wounds and gave him a soothing potion. Scarcely had he finished his work when the drunken man turned and struck him violently in the face. The doctor left in disgust, but as he was hurrying on his way the druggist came running after him with a bill of one franc and eighty centimes for the medicine given to the patient. The doctor refused to pay it and went his way. Some days after the doctor received two official letters, one calling on him to pay the druggist's bill, the other summoning him to court to testify with regard to his drunken patient. The doctor, who was a busy man, neglected both letters. He was soon after visited by a bailiff and compelled to pay a fine of forty-eight francs and also for the prescription, a total of forty-nine francs eighty centimes. Worse than all, the scandal aroused by the visits of the police so damaged his reputation before a prospective father-in-law that he missed "un beau mariage."

THE BACILLUS TUBERCULOSIS may have killed many men—it has made two, Koch and Spina.

BACILLUS LEPRÆ.—Cornil has recently demonstrated the presence of bacilli in leprosy tissues, and announces that he has found a new staining reagent by which the decomposition bacteria can be differentiated.

GERMAN VS. FRENCH SURGERY.—The *Medical and Surgical Reporter* calls attention to the alleged decadence of French surgery and quotes Verneuil's refutation thereof as follows: "If we appear to have thrown back operative surgery to the second rank, this has been in order to advance surgical therapeutics into the first rank. If we have shown but little eagerness to extirpate cancers of the larynx and uterus, to excise the œsophagus, the pylorus, or the lung, to tie the aorta, etc., this has been because our Gallic good sense has enabled us without difficulty to foresee the inevitable destiny of these extravagant vivisections, and that it appears to us of no utility boasting to-day of that which will be rejected to-morrow. If in our surgical wards we greatly hesitate to transport the results obtained in laboratory experiments, that is because we do not assimilate man with batrachians and rodents, or even with the mammalia, the most elevated in the animal scale." For all this, the Frenchman does not make out his case. The chief contributions not only to operative surgery, but to surgical pathology and therapeutics, have come in late years from other countries than France.

A METHOD OF RENDERING THE SKIN INSENSIBLE IN OPERATIONS WITHOUT CHLOROFORM.—M. Jules Guérin read a note at the Académie des Sciences upon a method of rendering the skin insensible in those operations which do not admit of chloroform by inhalation, and cited a case in which he had employed it to advantage. A lady, aged sixty years, consulted him three months ago for a tumor in the right breast of eight years' standing, which, on examination, proved to be scirrhus. The general health was bad, bronchial and cardiac troubles were manifest, and the kidneys were not in a very satisfactory condition. However, the operation was urgent. Chloroform having been considered dangerous, M. Guérin applied around the tumor a circular layer of Vienna paste, limited by a double band of diachylon. At the end of twenty minutes the caustic was removed, leaving in its trace a black ribbon-like line. The knife was then applied, and the tumor removed without the patient feeling the slightest pain, and who did not seem to be aware of the operation. The results were all that could be desired.—*Medical Press*.

THE TREATMENT OF WARTS.—Vidal recommends bandaging the wart-covered hands in flannel and green soap. After a number of applications the warts become softened and can easily be removed.

THE SOUND IN THE DIAGNOSIS OF GASTRIC DISEASES.—Leube calls attention to the very vague methods now

in use for determining the different forms of gastric trouble. He recommends the use of the soft sound for the purpose of more careful investigation. A healthy stomach should be completely empty seven hours after a moderate meal. By the sound we can determine whether it is really empty at this time. Specimens of the gastric juice can also be obtained, and its acidity tested.

CHRONIC CONSTIPATION.—Cascara sagrada, in doses of twenty minims three times a day, is said by many observers to be very efficient in the treatment of obstinate chronic constipation.

A SUBSTITUTE FOR IODOFORM IN THE TREATMENT OF WOUNDS.—Professor Ferd. Petersen, of Kiel, claims that zinc oxide is just as good as iodoform in the treatment of wounds, that it is not so poisonous, and is cheaper.

THE TITLE OF DOCTOR AND M.B.—Dr. N. O'D. Parks, of Ashton, R. I., writes: "I trust you will pardon me again troubling you to make more plain how preposterous is your London correspondent's contention. The sole ground on which the right to the title of doctor is claimed for the M.B., is that it is a University degree. On that ground, above all others, the claim is most untenable. Nobody ever hears, for instance, of a B.D. or LL.B. arrogating to himself the right to be called doctor, and there is no valid reason why a special privilege should be conceded to an inferior degree in medicine which is not accorded to the corresponding degree in law or divinity, both of which take precedence of the medical degree. There is one way, and one only, in which an M.B. can acquire the right to the prefix Doctor, and that is by proceeding to the higher degree of M.D."

CONCERNING THE REGISTRATION OF REGULAR PRACTITIONERS AND THE MEDICAL REGISTER.—A correspondent sends us the following: "In your issue of July 7th, it is stated that, 'In what for distinction's sake may be called the Physicians' Medical Register for 1883-84, a list of only 2,684 names is given, which *number represents the regularly educated physicians in affiliation with regular medical societies* (italics mine). The remainder are composed of homœopaths, eclectics, and non-descripts.' The above statement is incorrect for the following reasons: First, it mentions the Physician's Medical Register, as if its list were an official one, which, as I understand, it does not claim to be; second, the list does *not include* all regularly educated physicians in affiliation with, and in good standing in the Regular Medical County Society, or the Academy of Medicine; third, it is controlled by a 'private organization,' claiming the privilege of permitting or refusing registration to whom it will—the latter in cases where, to the best of my knowledge, it has not even attempted to allege, much more to prove, as cause for such refusal anything derogatory to the character or ability of such applicants for registration."

TO STOP HICCUGH.—Dr. W. E. Shaw, of Cincinnati, Ohio, writes: "I noticed the item by Dr. Martin Burke, in *THE RECORD*, of the 30th ult., 'To Stop Hiccough' by compression over the lower ribs. I have used compression successfully in quite a number of cases of persistent hiccough. The idea is not original, but was given me by my preceptor, Dr. W. P. Kincaid, of New Richmond, Ohio, about 1870. His method was to place the tips of the fingers of both hands in position of complete supination against the abdominal muscles, at the lower and outer junctions of the epigastric with hypochondriac regions. With the finger-tips in this position, firm and very gradual pressure was to be made backward and upward against the diaphragm. This pressure should be continued for some little time after the diaphragm has ceased its spasmodic contractions, when the fingers should be very gradually withdrawn."

THE STATUS OF PROFESSIONAL OPINION AND POPULAR SENTIMENT REGARDING SEWER-GAS AND CONTAMINATED WATER AS CAUSES OF TYPHOID FEVER;

WITH ALLUSIONS TO A PAPER BY DR. ALFRED L.
CARROLL UPON THIS SUBJECT.¹

[By GEORGE HAMILTON, M.D.,
PHILADELPHIA, PA.]

IN the discussion following a lecture upon this subject before the College of Physicians, March 7th, by the writer, the pre-eminent sanitary engineer, George E. Waring, declared "that the sewer-gas theory in regard to typhoid fever was, in the opinion of sanitarians, exploded." This declaration is in opposition to the teaching and recommendations of not a few engineers, who insist "that every effort should be made to exclude the gas from dwellings, regarding it as the general, if not the sole cause, not only of typhoid, but also of scarlet fever and diphtheria." This doctrine and these recommendations are in accord with the opinions, and have gained the support of a large majority of physicians. Many professors and editors of medical journals coincide with this view, and successfully impress its alleged correctness upon the minds of the inexperienced student and practitioner. Recently there appeared in a medical journal a paragraph from a somewhat prominent physician to this effect: "Is it not surprising and incomprehensible that there can yet be found physicians who deny the agency of sewer-gas in causing typhoid fever, diphtheria, and scarlet fever?" When it is stated that the writer of this quotation is one of the most positive in regarding sewer-gas as the effective agent in giving origin to the diseases named, may we not imagine another and greater surprise when he learns that this cherished and popular theory is exploded!

The paper upon sewer-gas, by Prof. Frank H. Hamilton, published some months ago in the *Popular Science Monthly*, with its numerous quotations, cannot be regarded as antagonistic to the opinions heretofore and at present held by many physicians, sanitarians, and the public generally. The special object of that paper was, in fact, to devise more reliable measures to exclude from houses this asserted source of disease; and, to accomplish this object, scientific plumbing, with improved apparatus erected in an annex, outside of the residence, was recommended. Efforts to exclude the gas are unceasing up to the present moment; neither is this strange, in view of what has just been stated. Whether the typhoid, the scarlatinal, or the diphtheritic germ, or some special quality of the gas itself, dependent upon peculiar substances finding entrance to the sewers, and subjected to various degrees of warmth and moisture, be the supposed noxious agents in question, is immaterial; for, practically, to admit the gas is to admit one or all of these agents; to exclude the gas is to exclude them. Attempts have recently been made to underrate the agency of sewer-gas in causing typhoid fever and other diseases. Efforts in this direction are, doubtless, made by those who frankly confess that the reports of the Board of Health of this city, New York, and elsewhere, are strongly in opposition

thereto. Nor is this all; for a large majority of practitioners, who have had the most frequent and abundant opportunities to observe the origin, development, and progress of typhoid fever, either withhold their assent to the current views upon this subject or positively deny that sewer-gas is the sole cause of this fever, or that it exceeds all other agencies, combined, in its production.

In this connection, does it not seem passing strange that, while the Trousseaus, the Niemeyers, the Murchisons, the Bristowes, the Flints, the Jacksons, and many others of similar experience and capacity, entertain doubts in regard to certain points pertaining to the origin of typhoid fever, and express their opinions in relation thereto with calm, philosophic, commendable reserve, many others, of different qualifications and temperament, find no difficulty of this kind, but, on the contrary, armed *cap-à-pie*, are always ready and eager to solve any question in regard to this subject? Unfortunately, these attempted solutions are too often merely bold, positive assertions, having no real basis of support, as is exemplified in the declaration by some, "that the families located in the wealthy and fashionable parts of Philadelphia and New York, are most liable to attacks of typhoid fever;" while the reports of the Board of Health of both cities show, on the contrary, that the suburbs exhibit by far the largest number of cases. This accords perfectly with the testimony of the late distinguished Professor, John K. Mitchell, quoted in my paper of the 7th of March, who, in consultation, informed the writer and the late Dr. Louis P. Gebhardt, "that he seldom saw cases of typhoid fever except on the outskirts of the city," where water-closets were scarcely known. One of the chief embarrassments of those who would fain be wise above that which is written, is to account for the greater prevalence and fatality of this disease in the country, and to avoid this difficulty, *coûte que coûte*, a reason for this must be given. To escape the dilemma in which they are placed, the drinking-water in the country is declared to be contaminated from the adjacent or remote privy. Now, this assertion should, if believed, inspire far more dread than the sewer-gas theory ever did, even in its palmiest days, long before the recent decree that it had been exploded was announced. What must now be the state of mind of the laborious farmer and family in reflecting that to his own negligence or stupidity is he indebted for this sad condition of his household? But the mischief does not end here; for what, it may rationally be asked, is to become of the thousands upon thousands of our citizens who, every summer, gladly visit the country and seek boarding with the farmer, or select for a season the accommodations furnished by cottages or hotels, many of them for the express purpose of escaping, as they declare, the heated and impure air of the city, and the contaminated water of the Schuylkill, receiving, constantly, as it is said, an immense amount of impurity from Manayunk, and many other points nearer to Fairmount? As is well known, not a few of the country people, on visiting the city, alarmed by the exaggerated reports of the condition of the water, abstain as far as possible from its use. But admitting the supposition, and it is nothing more, to be true as to contamination of the water in the notably beautiful rolling country of the counties around Philadelphia, how are we to explain the fact that, at uncertain intervals, a severe epidemic will suddenly appear, fever sometimes, dysentery at other times, and will just as suddenly disappear, and neither of these

¹ See MEDICAL RECORD of June 9, 1883.

diseases again be seen to any extent for one or several years ; precisely as has often occurred in this city and elsewhere ? To suppose that the water has thus suddenly changed from purity to impurity, and again as suddenly to purity, without perceptible or conceivable cause, either by the family physician or the family, is simply absurd.

Such a statement as was made in the discussion alluded to, regarding the condition of what were termed country towns in New England, can have but limited application, and is completely at variance with the contents of a letter from a prominent physician in a New England State, who, after inquiry in reference to outbreaks of typhoid fever, had replies from about fifty practitioners in that State to this effect, that the rural sections suffered by far the most from epidemics of typhoid fever. Any one who has travelled over the rural sections of New England could not have failed to observe the generally good condition of the farms, whatever he may have noticed of an exceptional character in some places. But why go from our own city or vicinity ? Have we not in this city, or within an hour's journey, numerous factories and densely peopled districts, notorious, when compared with the country, for their filthiness ; with cesspools and innumerable privies almost in contact with dwellings ; and, in many cases, from the porous nature of the soil, filled to repletion, thus affording every opportunity for the contamination of the water in comparison with the country ?

To show how delusive plausibly written accounts of the origin and spread of typhoid fever may be, let the following suffice : A woman, after nursing a relative during several weeks, returned, after the death of the patient, to her own residence, distant three miles. In a few days she was prostrated with typhoid fever, the disease of the relative. In succession one after another was attacked until four out of seven members of the family were down with the disease, one death ensuing from perforation. In the discussion of the paper one of the speakers thought there could be no difficulty in accounting for the attacks of the last three patients, as the dejections from the bowels of the first patient were (probably) cast down in such way as to admit of drainage into the drinking-water, and that thus the typhoid germs were received into the stomachs of those last attacked. But, unfortunately for this solution, the drainage descended from the source of the water to the outhouse.

In another family of eight persons, quoted in the lecture of March 7th, seven were attacked with the fever, all of them dangerously, except a colored servant. As in the former case the disease did not originate upon the premises. A son had been sent into Maryland—distance forty miles—and after remaining there several weeks was brought home, affected with typhoid fever ; and in succession his two brothers, two sisters, and last of all, his father and the servant were attacked. The dwelling was upon the slope of a hill, and, as in the former case, the drainage descended from the water in the direction of the outhouse ; so that contamination of the water in either instance was impossible. Typhoid and scarlet fever, diphtheria and dysentery may not, under favorable conditions, be contagious ; but under opposite conditions, as when these diseases are malignant, and the patients crowded together—for example, three in the same room—as occurred in the family just alluded to, they are regarded by an immense majority of the most able, unprejudiced and experienced physicians as eminently contagious.

Colonel Waring, to his credit be it said, was commendably conservative in the discussion, not disposed to be dogmatic, and, in regard to this special point, said that "the literature of the subject *seems* to prove that typhoid fever in the country is due to drinking-water which has become contaminated," knowing, doubtless, full well that a score of probabilities are powerless when confronted by a single irrefutable fact.

To revert for a moment to sewer-gas, it appears from

the remarks of one of the disputants to be now placed in a worse position than ever ; for while it is admitted to be the *vehicle for conveying typhoid germs, when it contains them* (?), it is also declared to be "the most potent cause of the typhoid state." The importance of this statement will at once be appreciated when we call to mind that the typhoid condition is the almost invariable concomitant of the latter stages of nearly all dangerous and fatal diseases, whether acute or chronic. During the discussion repeated appeals were made on behalf of cleanliness. But who ever heard of any one, who had the least regard to the amenities of life, opposed to cleanliness ? for is it not said to be "akin to godliness ?"

The criticisms by Dr. Alfred L. Carroll upon my lecture of March 7th, published in THE MEDICAL RECORD of June 9th, are, the writer thinks, rendered in great measure nugatory by certain uncontroverted and incontrovertible facts above stated ; yet special notice will now be taken in reference to some points in the critique.

The diagnosis of typhoid fever is declared by Dr. C. to be unsettled. But why so ? Is it because it has been known to appear suddenly upon a mountain-peak in Tennessee or Western Virginia, in their almost pristine condition, far removed from sewers, or "the walled-up and leaching privies of cities or of filthy villages," where some may say it should not have appeared ; or, on the other hand, in the filthiest of cities in Asia and Africa it rarely appears, despite the filth and stench for which they are noted. The diagnosis depends upon no contingent, exceptional features in its history. Who that has ever read Louis, Andral, or Chomel, or Bartlett in our own country, and, in an especial manner, the works of that master-mind in medicine, Austin Flint, Sr., could say that the diagnosis of this disease is unsettled ? Like very many other affections, either from idiosyncrasy, or complications, doubts may arise ; yet this militates not against its normal aspect, one of most singular and pronounced character, so that he who is familiar with the disease will incur slight risk of a mistake in diagnosis. Error as to frequency and fatality in town or country is impossible, if statistics are consulted.

Dr. C. asserts that sanitarians have not ascribed prominence to sewer-gas as a cause of typhoid fever. The facts above stated on this point prove the contrary. According to Dr. C. a majority of cases of this disease have been *accurately* traced to contaminated food and water ; yet in my own extensive experience not one such case has (to my knowledge) ever occurred, and those reported are probably in the same predicament as those alluded to in the discussion as referable to contaminated water. The term sewer-gas is said to be misinterpreted, but is it not just as definite in signification as the terms spring-water, sea-water, river-water, mountain air, etc. ? Next it is declared that "the filth of the country is atrocious compared with that of the city, and that for one source of filth in the city there are three in the country ; and that one prolific cause of this may be found in the numerous unventilated vaults." In reply to this sum of abominations of the country and villages, compared with a city, the writer must declare that, after ten years of practice in the country, he has seen nothing that could present the shadow of a parallel to the statement just made. On the contrary, a walled, unventilated well was scarcely ever seen in the rural section where he practised, but in lieu thereof a simple fosse, not very deep, was dug, and from time to time the contents covered with fresh earth and in the fall or winter removed to the fields. This then is just the condition that Dr. C. regards as involving only slight danger, while the walled-up, unventilated privy is a nuisance worthy of the severest denunciation. Where then do we find these dangerous wells in great number ? As every one knows, in the cities, and in many cases, as in Philadelphia and New York, reaching to tens of thousands.

In my lecture it was stated that in "not more than one house out of five could any sign of sewer-gas be

detected. This, of course, had reference, to the city, not the country. While Dr. C. is quite excusable for this oversight, his thrust at the country physicians, in declaring that very few of them care to *learn how* to look for the causes of disease, may not be regarded in so favorable light, especially when we reflect that Trousseau designated the country physician as in the best position by far to discover the origin, development, and progress of typhoid fever; and truth compels me to assent to this declaration. In forty years of city practice no such opportunities for observing the origin and character of the disease were afforded the writer as during his ten years of country practice; and this may well appear from the fact that, in city practice, only one case in a family has occurred—three families alone excepted, in two of which two, and in the third family, four persons were affected. In this connection it may be stated that in the course of twelve months four cases of intestinal perforation occurred in my practice.

Dr. C. most truly informs us, "that facts are more forcible than words;" and what sane man can object to this forcible truism. Let us, however, put to the scrutiny a fact or two adduced: "Agricultural laborers," he tells us, "do not spend all their time in the fields," for they need sleep, and, thus far, very good. But when he asserts that "as a class they carefully exclude all ventilation from their rooms," we must dissent, *toto codo*. The most laborious and exhausting work of the laborer is during the hot weather of the harvest-time, and, as a rule he is apt to retire early in the evening. But, unfortunately, the room of the laborer is very often in the upper story or garret, and this very frequently is without ceiling, and the rays of the sun pouring down upon the roof during the long days of summer, renders the atmosphere of the room in a measure stifling; and, instead of excluding the air, he longs for the excessive heat of his room to pass away, as experience tells him it will, just as the night passes away, and the well-known refreshment of the morning hours draws near. In this connection it should be noted, that when epidemic dysentery prevails (in the country), many of the attacks are attributed to the excessive change of temperature from the early night to the morning hours, causing (during sleep) sudden and violent retrocession from the cutis to the abdominal organs. Healthy young males are said by Dr. C. to be especially prone to attacks of the fever, and here, we think, he is right, although in opposition to the view of Dr. F. H. Hamilton; but if, as he asserts, fragile women are better able to resist *infection* than strong women or men, it is contrary to general experience; for debility, no matter how produced, increases the liability to such infection or contagion; while it must be confessed that males or females of moderate physical conformation, if healthy, support acute diseases better, and are more likely to escape a fatal termination than the rugged and over-sanguine. Facts that have the appearance of causes are alluded to, but these, although constantly brought forward, can have, and should have but slight influence in determining questions of serious importance; for one proven, irrefutable fact, in contra-vention, outweighs a score of them.

About two columns of THE RECORD are taken up with a list of houses in which typhoid fever or diphtheria occurred. Every one of these houses, whether large, elegant, and furnished with conveniences, or small, and of an opposite character, had this in common, that in regard to filth, in one form or another they were simply abominations, and hence, were just the places (as many think) for an outbreak of these diseases, of which six were typhoid fever; and let it be borne in mind that Dr. C. has excluded cases where contaminated water might be thought to have had some influence in causing these outbreaks. But what of all this? If eleven cases of typhoid fever, as stated above, could occur in only two houses, having no such abominations of filth, nor of contaminated drinking-water, why may they not occur in houses

such as Dr. C. describes? for, beyond all question, filth should confer no exemption from these attacks. Dr. C. intimates that persons who are habituated to the influence of agents productive of typhoid fever are seldom quite well, and, on the contrary, my experience is that young and healthy men are, especially in the country, attacked despite their actual good health.

In connection with, and conclusion of this subject, the writer must again put on record the testimony of Dr. John Syer Bristowe, President of the Society of Medical Officers of Health, confessedly one of the most sagacious observers and logical thinkers of the day, who writes as follows: "If we look to the remarkable influence which *simple variations of temperature and peculiarities of season* exert on the mortuary returns, in respect both of the number of deaths and the character of the fatal diseases, and compare therewith the comparatively small effect on the death-rate of even one of the most fatal of the zymotic diseases, or with the insignificant influence of deaths from enteric fever, diphtheria, and other affections, *over which sanitary science is supposed to exert a specially valuable influence*, we can scarcely avoid seeing that, on similar grounds, the deaths saved directly by the sanitary labors on which we are engaged must, under any circumstances, be so few annually as to produce *no distinct and unmistakable effect on the mortuary rate.*"

This sincere and ingenuous avowal of opinion by one, not only distinguished as an author and teacher, but who, in his exalted official position, had every opportunity to scrutinize all facts regarding outbreaks of typhoid fever, scarlet fever, and diphtheria, as bearing upon the question of their prevention, may well be commended to the serious consideration of those who, for years past, have positively promised the extinction of these diseases, under certain impossible conditions, yet with no other result than that just presented by the above-named conscientious and eminent authority in medical science.

THE TREATMENT OF ECZEMA IN PRAGUE.

By ROBERT B. MORISON, M.D.,

BALTIMORE, MD.

SINCE the introduction by Professor Pick of medicated gelatines for the treatment of various skin diseases, there has been a most decided advance in the simplicity of such treatment and the results have been correspondingly good. Jarisch¹ said of chrysophanic acid gelatine, introduced a year ago: "The problem is solved of retaining the favorable action of chrysophanic acid upon psoriasis, and at the same time of eliminating any injurious secondary effect."

For more than a year eczema has been treated in the dermatological wards under Professor Pick in Prague, by the so-called medicated gelatine bandage, and an interesting article on this subject was read by Professor Pick² before the Verein deutscher Aertze, January 26, 1883. The difference in treatment of this disease between Vienna and Prague is striking in the extreme. In Vienna there has been no change made since the great Hebra gave the rules which are so universally followed. With the exception of the introduction of naphthol by Kaposi, and which is used only in his wards, tar still holds the chief place in the Vienna treatment of eczema.

Though being far from criticising the excellent results obtained from this agent, I could not but be struck with its uncleanness and disagreeable odor. As one passes through the wards in Vienna the patients are seen lying upon beds between two blankets, which, from the constant use of tar, have become so impregnated with it that the picture is anything but an agreeable one. Add to this the patient himself, covered often with a thin layer of this dirty-looking mass from head to foot, and

¹ Centralblatt für die gesammte Therapie, Heft I., 1883.

² Prager Medicinische Wochenschrift, No. 6, 1883.

one realizes that such treatment can only be used as a *dernier ressort*.

The importance of tar, however, being recognized by every dermatologist, it has been the desire of each one to obtain from it some essential ingredient which they hoped could be used as effectively and yet do away with its unpleasant application, but unfortunately neither the resinone, or resinin, or carbolic acid, or any of the other products of distillation contain all its virtues.

Even naphthol, so highly praised by Kaposi, and which certainly has some virtues, has not been able to take the place he first hoped it would.

This latter drug is now used almost exclusively in scabies alone, and even in this disease great care must be taken not to produce an inflammation leading to eczema from its universal application. The intensity of inflammation which it sometimes produces, and which far exceeds the application of tar itself, throws it entirely out of the field as a rival of the latter. This is the conclusion which all authors have arrived at after a somewhat prolonged trial since its introduction.

The general laws laid down by Hebra in the treatment of eczema were soothing applications in the acute stage, tar in the dry stage, and macerating applications in the chronic stage.

A patient was powdered with some inert powder until the acute inflammation and moist stage were passed, then tar applied and a cure accomplished.

The amount of labor and nursing required to treat the patient thoroughly according to these rules, to say nothing of the time lost by the patient when in the hospital, where it was necessary he should be, was very great. In chronic cases the time was lengthened so much the more because it was first necessary to render the disease acute by the various macerating applications before the regular treatment could be entered upon. That the results of this treatment, however, were most excellent could not be denied, but that it left nothing to be desired was far from the opinion of the author himself who was always trying to improve upon it.

The efficacious action of tar is generally conceded to be due to the mechanical protection which it affords to the skin and to its antiseptic qualities. There is so much chance for a mycotic appearance to be engrafted upon the moist stage of eczema (*e. madidans*), that it is one of the strongest arguments for the application of a drug if it has antiparasitic or antiseptic properties. Recognizing to the fullest extent this important property of tar, and being unable to find in any of its derivations a substitute for it, Professor Pick conceived the idea of supplying its place with some other medicine, which also possessed antiparasitic and antiseptic qualities.

For three months I have been studying closely and critically, through the kindness of Professor Pick, his gelatine treatment of this disease, and I have been greatly struck with the simplicity of its application, its cleanliness, and its most excellent results. Instead of the troublesome use of powders and salves, which in Vienna must be applied at least twice a day, the patient in Prague has immediately wrapped over his diseased parts linen bandages smeared with unguentum saponis containing five or ten per cent. salicylic acid. This is applied in any stage and left *in situ* for a week.

After the bandages are applied they are covered with what is known as tricot, and which is manufactured, in various sizes and at small expense, especially for Professor Pick in England. A patient thus dressed is able to go about his work with no inconvenience to himself, and no injury to his clothes. After a week's time he appears at the hospital, the bandage is removed, and the disease examined. If it is found necessary, from the still remaining inflammation and induration, a fresh bandage is applied and left on for another week. Then the gelatine is applied in the following manner: A portion of a mass made by dissolving fifty grammes of the purest gelatine in one hundred grammes of distilled water, and

which has been allowed to cool previously, is melted by putting it in a cup and placing the cup in hot water. To this is added the required strength of salicylic acid, usually five per cent. When sufficiently cool this mixture is painted upon the diseased parts with a painter's brush made of bristles, such as is used in applying tar. The layer of gelatine is made about as thick as a sheet of writing-paper, and after it has dried is gently covered with a minimum quantity of glycerine spread on with the hand.

The use of glycerine is found to be necessary to render the gelatine layer pliable and to prevent its contracting, which it otherwise would do with considerable force; sufficient to irritate the skin. It is also worthy of note that it is not practicable to mix the glycerine with the gelatine before it is applied, as it prevents its hardening sufficiently and renders it sticky. It takes a very small quantity only of glycerine, after the gelatine has dried upon the skin, to render it soft and pliable. A few trials teach the nurse the amount required. This use of glycerine obviates the only bad effect which the gelatine can possibly have. With such a gelatine bandage a patient seldom feels the slightest itching, the diseased parts are seen through the transparent layer, thus rendering the progress of the disease visible without the removal of the application, and, what is much more agreeable to the patient, an ordinary bath removes all traces of it. So easy is this method of treatment that the patient can make his own applications in most cases, and there is no fear of a too strong action to be produced by the drug. In many cases of chronic eczema the application of this medicated gelatine is made immediately without the previous use of the above-mentioned linen bandages. Also in acute eczema, especially in *crusta lactea*, this rule may often be followed. There is no reason why the medicated gelatine should not be immediately applied in any cases of eczema at any stage; but experience has shown that salicylic acid first applied in the moist stage of acute eczema in the form of salicylicated soap ointment for a period long enough to reduce the inflammation, renders the use of medicated gelatine more prompt in its results.

Through the kindness of Professor Pick's assistant, Dr. Strach, I have been able to obtain the history of the following cases, which, among many others, I have personally watched:

CASE I.—F. D.—, a man, aged fifty-eight, book agent, entered the hospital May 23, 1883, suffering from chronic eczema. This had troubled him for ten years; it first began with intense itching, and the skin soon became chronically inflamed from scratching. Also suffered from constipation. The patient is a large, well-built man, but somewhat pale and thin. On both legs, extending from the toes to a little above the knee-joints, the skin is livid, somewhat tense, and here and there covered with easily removed crusts, leaving a moist surface exposed, the skin of the thighs on both sides thickened, and in some places covered with pustules and vesicles. The corresponding situations upon the arms show the same changes. On the day of entrance was ordered a ten per cent. salicylic acid soap plaster, made according to method above described. On the 28th salicylicated gelatine smeared upon all the diseased portions, except the knee-joints, which still retained the plasters. On the 30th all the plasters were removed and the patient sent out so far cured that he could himself apply further treatment at home.

CASE II.—M. K.—, aged fourteen, daughter of a shoemaker, entered the hospital March 6, 1883, suffering from eczema capillitii. A year ago the patient came to this hospital for the same trouble, and was sent home cured after ten weeks' treatment with white ointment and tar. This attack has existed fourteen days. The scalp, especially the posterior portion, is covered with a thick mass of crusts, piled upon each other so that the hair is closely matted together. The skin of the ears tense and

inflamed, moist and painful. On the 7th salicylated soap plaster was ordered; internally, cod-liver oil. On the 15th tar was applied to the scalp, while the forehead and ears were treated with salicylated plaster, and this was done in order to compare the two methods conjointly. This treatment was continued until the 18th of the following month. In the meanwhile the plasters on forehead and ears, having performed their required work, were removed, salicylated gelatine applied in their place, and the disease cured. The scalp treated with tar was still quite inflamed, and though better, had not progressed as favorably as the other parts. At this time the tar was discontinued and salicylic acid used in its place. On April 30th the patient was so far cured as to be sent from the hospital.

CASE III.—J. L—, wife of a house-porter, entered the hospital April 4th, suffering from eczema universale. The patient has had the disease on both feet for two years, which began to spread to other parts four weeks ago. Home treatment was used, and also white ointment and tar, which was ordered by a physician, without any change for the better. She is a large, fat, well-nourished woman. On the forehead was a papular efflorescence, on the face a vesicular eruption, which in places was covered with crusts, exposing when removed a moist surface. The same appearances on the neck, legs, arms, and trunk. On the 10th was ordered a ten per cent. salicylated soap plaster.

On the 18th, plasters taken off; skin found much less inflamed, and only in some places was the epithelial regeneration imperfect. To such places fresh plasters were again applied, while a five per cent. salicylated gelatine was ordered for the rest of the body. On the 16th, the patient was so far cured as to be sent from the hospital with instructions how to apply the gelatine at home.

CASE IV.—A. F—, wife of a shoemaker, aged twenty-seven, entered the hospital March 20, 1883, suffering from eczema chronicum faciei. The patient had suffered for three years. It began during pregnancy, disappeared just before birth, and came on again while nursing. Was treated in this hospital a year ago with white ointment and tar. The eczema is situated upon the face and forehead, extending behind the ears and slightly into the hair, also upon elbow-joints and knees. Was ordered to be applied ten per cent. salicylated soap ointment immediately to all the diseased parts. This was changed twice in two weeks, and the condition of the patient much improved. Gradually increasing doses of Fowler's solution of arsenic were ordered, but after two weeks was discontinued on account of the gastro-enteritis which it caused. The third week after entrance salicylated gelatine was applied, and on May 1st the patient was dismissed cured.

CASE V.—W. K—, a girl, aged twenty-two, entered the hospital, suffering from eczema impetiginosum universale. Was immediately ordered ten per cent. salicylated soap ointment, which was applied in the following manner: The toes and fingers were closely wrapped with short, narrow bandages, smeared with the ointment; legs, arms, and trunk with longer and wider bandages, while the head and face were completely covered in the same way. Over this was drawn the closely fitting tricot bandages, made to fit all the irregularities of the body by the skilful use of a few stitches. Thus covered completely, with only holes left for eyes, nose, mouth, etc., she could lie comfortably in a clean bed, or be dressed and wander around the wards. On the 23d, the soap plaster was removed and reapplied to all parts, except the face, which was painted with a five per cent. salicylated gelatine. On May 14th, the infiltration had so far disappeared that the plaster was taken off and the gelatine applied everywhere. On June 9th, it was found advisable to reapply the plaster to the knees and elbow-joints, and these were easily kept in place by slightly overlapping them with the gelatine. On the 11th, all plasters were removed, and the treatment confined to the

use of gelatine. On the 14th, the patient was dismissed cured.

The most satisfactory results, however, both to patient and physician are obtained in the chronic cases which appear so frequently at dispensaries. For instance, in cases due to varicose veins, I have seen the greatest benefit follow it. Instead of taking the patient into the hospital, he is simply bandaged and sent off, to return in a week's time. Nothing could be simpler, and it is satisfactory in the extreme.

In trying this treatment, there are a few points in the method of application which it is necessary to insist upon.

The salicylic acid must be thoroughly well mixed with the soap ointment whilst warm, and this must be spread, when at about the consistency of butter, evenly upon short linen bandages, which should not be more than one and a half inch in width, and even much narrower when applied to fingers or toes. The ointment should not be in a thicker layer than the back of an ordinary table-knife, and should be spread fresh every time it is used. It is well not to mix up too large a quantity of the ointment, as upon standing it hardens and is more difficult of application.

The gelatine should be prepared by dissolving in distilled water and heated in a porcelain crucible. After stirring thoroughly it is allowed to cool, and forms a cake, which takes the form of the crucible. This cake can be kept for any length of time in paper, and the necessary quantity broken off every time it is to be used.

The salicylic acid must be kept separate from it, and only added to the gelatine when it is melted. The mixture should not be painted upon the skin unevenly or in a thick layer. When properly applied it can be torn from the skin in quite large pieces, and it comes off without pain to the patient, or irritation to the disease. It sounds like the tearing of tissue-paper, and when thus torn off looks as if the patient was having his epidermis removed by force.

Any holes or rents in the gelatine covering may be repaired from time to time by a fresh application. The indications for the renewal of the whole covering are when it has worn off or after a bath.

After having seen as many as a hundred cases of eczema treated by this method, I consider it fully equals the old tar treatment in the results obtained, and that it far surpasses it in the simplicity of its application and in its cleanliness, a quality which recommends it immediately to the patient.

With its introduction, Professor Pick has made a great advance in the treatment of this most common of all skin diseases, and it is worthy of a most thorough trial in the hands of others.

THE MEDICAL VOYAGE OF LIFE.—First year: icterus neonatorum, hyperkinesis intestinalis, and vaccination. Second year: dentition, croup, cholera infantum, and fits. Third year: diphtheria, whooping-cough, and bronchitis. Fourth year: scarlet fever, worms, and meningitis. Fifth year: measles. Now half the children are dead. Seventh year: mumps. Tenth year: chorea and typhoid fever. Fifteenth year: hyperæsthesia sexualis. Sixteenth year: spermatorrhœa, chlorosis, and spinal irritation. Eighteenth year: blennorrhœa urethralis. Twentieth year: bubo, alcoholic cephalalgia, vertigo. Twenty-fifth year: matrimony. Twenty-sixth year: insomnia de infanto. Thirtieth year: dyspepsia, nervous asthenia. Thirty-fifth year: pneumonia. Forty-fifth year: lumbago, presbyopia. Fifty-fifth year: rheumatism, alopecia. Sixtieth year: amnesia, deciduousness of teeth, bony arteries. Sixty-fifth year: apoplexy. Seventieth year: amblyopia, deafness, anosmia, general dyskinesia, atonic digestive tract, rheumatismus deformans. Seventy-fifth year: finis.

AN EAR-RING.—A convention of Otologists.—Puck.

THE SIGNIFICANCE OF THE TRANSMISSION OF SOUND TO THE EAR THROUGH THE TISSUES IN AURAL DISEASE.¹
